CELL OUT!

(by ultrasonics)

Our micrograph shows the membrane of a cell of baker's yeast, the contents of which have been expelled by means of an **MSE-MULLARD Ultrasonic Disintegrator.**

Scientists will readily appreciate from this simple example the advantages of the utilisation of sound energy for the disruption of plant and animal cells, bacteria, viruses and even large molecules This Disintegrator has, indeed, gained rapid recognition as an invaluable aid in the preparation of antigens, for the extraction of enzymes and toxins, and in the study of intercellular components

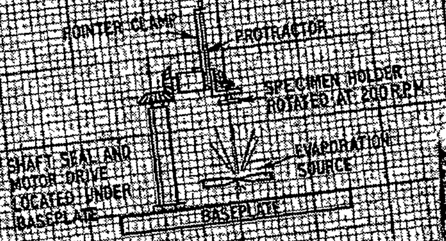
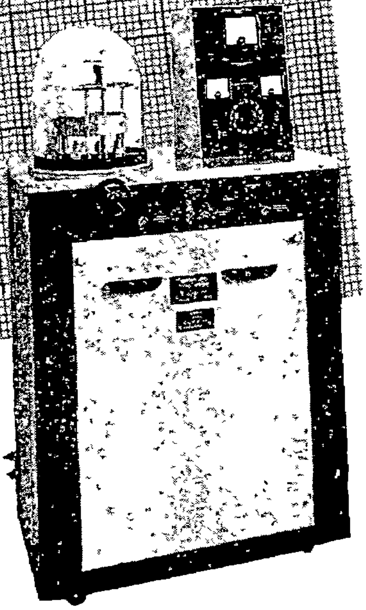
CONE SHADOW-CASTING ACCESSORY

ENABLES SPECIMENS TO BE ROTATED AT 200 R.P.M. DURING SHADOW-CASTING, E.G., PLATINUM-CARBON SHADOWING



POINTER CLAMP
PROTRACTOR
SPECIMEN HOLDER ROTATED AT 200 R.P.M.
EVAPORATION SOURCE
SHAFT SEAL AND MOTOR DRIVE LOCATED UNDER BASEPLATE
BASEPLATE

SPECIMEN HOLDERS AVAILABLE FOR GRIDS OF 2 3 mm AND 3 mm DIA.



The body of the rod is spectrographically pure graphite having a short core at one end of a mixture of finely powdered graphite and platinum (by weight 85% platinum and 15% carbon) Different film compositions can be obtained by using the rods in pairs or in conjunction with plain graphite when a smaller percentage of platinum in the film is necessary These rods can be fitted to the standard carbon evaporation source supplied with "Speedivac" 12E6 vacuum coating unit which has been specially designed for electron microscope work

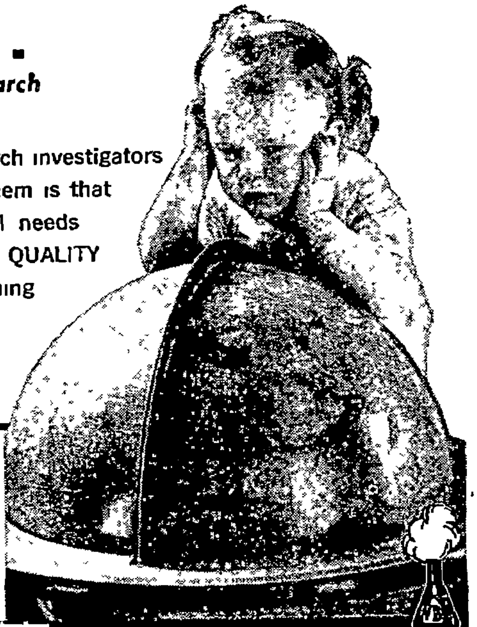
THERE'S A REASON . . .

why Nutritional Biochemicals Corp. is the largest research biochemical house in the world!



Yes . . there's a reason, actually several of them, why more research investigators rely on NBCo than any other biochemicals organization One of them is that NBCo is the most COMPLETE source for ALL their biochemical needs They can depend on every NBCo chemical to be of the HIGHEST QUALITY . . . at the LOWEST POSSIBLE PRICE! And finally . . NBCo's lightning FAST SERVICE (all orders shipped within 8 hours of receipt!) Yes, thousands of organizations are capitalizing on the many advantages Nutritional Biochemicals Corp can offer Are you?

Our stock of more than 2,500 items includes • OVER 300 AMINO ACIDS • OVER 90 PEPTIDES • MORE THAN 200 NUCLEOPROTEINS, PURINES, PYRIMIDINES • MISCELLANEOUS BIOCHEMICALS • VITAMINS • ENZYMES CRYSTALLINE, PURIFIED • GROWTH FACTORS • STEROID HORMONES • BIOLOGICAL SALT MIXTURES AND TEST MATERIALS • CARBOHYDRATES • PURIFIED PROTEINS • FATTY ACIDS • ANTIBIOTICS • ALKALOIDS • GLANDULAR SUBSTANCES

OUR NEW OCT. 1959 CATALOG
containing more than 2,500 items is now ready Fill out coupon below and mail today for your free copy.

* *Two new books from John Wiley & Sons, Inc* *

THE MOLECULAR BASIS OF EVOLUTION

by C[illegible]AN B. ANFINSEN

241 pages *Illustrated* *56s net*

This book proposes a biochemical approach to the study of evolution, the latter being considered as the integrated form of the sciences of genetics and protein chemistry The protein chemist, especially, will benefit from this view of what is happening in a fast growing area of chemistry and genetics, but the book will also be of interest to medical research workers and to students studying the general framework of evolution

SPACE TECHNOLOGY

Edited by HOWARD SEIFERT

1,048 pages *Illustrated* *180s net*

Thirty-eight experts in their respective fields present analytical treatments of all phases of space technology The subject of ballistics and flight dynamics—the foundation of space travel—is treated in an especially complete and analytical way, with 11 authors presenting new material The next most vital subject—propulsion—is treated by 7 authors and covers both present-day and future systems Major sections are also included on communications and guidance, man in space, and scientific uses of space.

Colour photography at *high speeds*

The introduction of a new colour film that is faster than many black-and-white photographic materials opens up interesting possibilities for research workers The film, Kodak High-Speed 'Ektachrome' Film, has a speed rating of ASA/BS 160 BS log 33°
Where coloured dyes are used as markers, in metallurgical analysis by flame propagation, in photo-recording where high-speed galvanometer traces overlap and need to be identified by colour, in photo-elastic stress analysis, in Schlieren photography, and in many other fields where high-speed transients and identification by colour go together, the unparalleled speed of this new colour film will be appreciated.

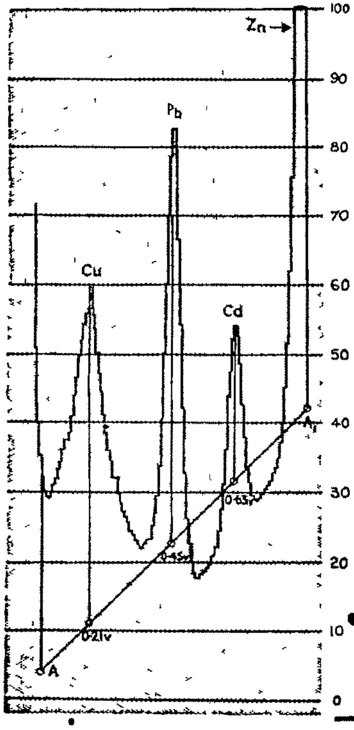
Kodak *high speed*

'Ektachrome' film

Full details from Kodak Limited, Industrial Sales Division, Kodak House, Kingsway, London, W C 2

*** COPPER · LEAD · CADMIUM....with ZINC**

How long would it take to analyse



by CONVENTIONAL METHODS, a solution having the following metals present —

COPPER	3 p.p m.	CADMIUM	2 p.p m.
LEAD	7 p p.m	ZINC	200,000 p p.m. ?

These Square Wave Polarograms recorded by the

MERVYN-HARWELL
SQUARE WAVE POLAROGRAPH Mk. III

are reproduced here to show the identification of these metals, in these proportions, in solution. Note the high ratio of Zn to Cd., without interference The peaks are identified by the automatic potential markers AA1, which enable half-wave potentials accurately to be established. Permanently recorded on a 10" wide chart.

**This was an actual problem presented to Mervyn Instruments by a leading chemical manufacturing organisation.*

Speediest, most Accurate, the Fundamental Development in Analysis—and therefore the most Economic Convenient in Design, Sensitive in Application.

Send for our full technical leaflets, quoting "Nature" to

LABORATORY INSTRUMENTS

Their Design and Application

by A ELLIOTT, PH D, D SC, & J HOME DICKSON, M SC

SECOND EDITION—REVISED

530 *pages* *Illustrated* 55*s* *net*

This book is based on the experience of many years of research work It presents the principles on which good design is based, and gives many examples of practical applications As in the previous edition, the authors have confined themselves wholly to mechanical and optical matters, but the original text has been thoroughly revised and much new material added

DETOXICATION MECHANISMS

The Metabolism and Detoxication of Drugs Toxic Substances and other Organic Compounds

by R TECWYN WILLIAMS, PH D, D SC

SECOND EDITION—REVISED AND ENLARGED

806 *pages* *Illustrated* 126*s* *net*

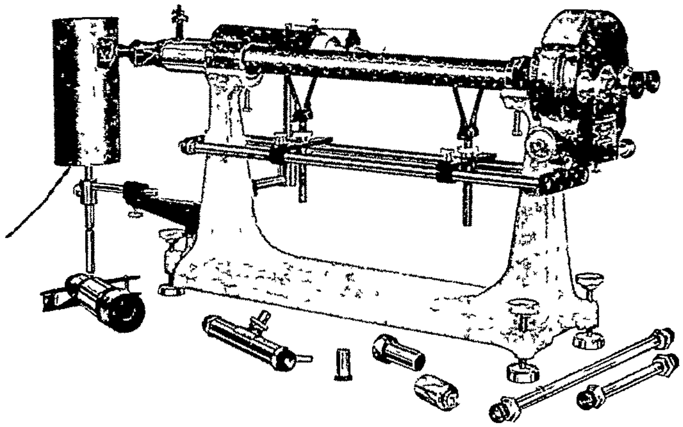
When the first edition of this book appeared twelve years ago, it was the first monograph to be published in English describing the chemical changes which drugs or other substances foreign to the body undergo when administered to animals At that time the available information on the fate of foreign organic compounds in the animal body was fragmentary Since then, the increase in the knowledge in this field has been so great, that the book has had to be completely rewritten and enlarged to two and a half times its original size

37 ESSEX STREET, LONDON, W C 2

PRECISION INSTRUMENTS

Polarimeter Model A

This instrument gives the highest degree of accuracy with divided circle on glass reading to 0·01 degree



- Circle centre on ball bearings
- Easily removable trough
- Divided drum replacing verniers
- Stationary observation telescope
- Circle reader enlarging image of scale
- Slow motion adjustment always in action
- Suitable, with additions, for measurement of rotatory dispersion

This polarimeter has been supplied in large numbers both in this country and abroad and has always been acclaimed as being of advanced design and workmanship

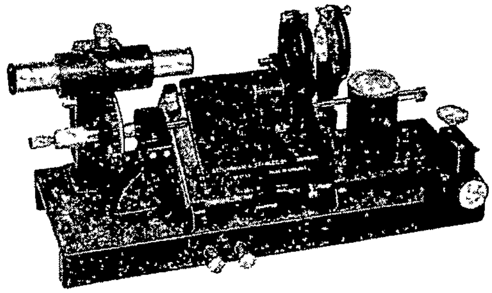
PRECISION B&S INSTRUMENTS

Fabry-Perot Interferometer



Although of very simple design, this instrument is suitable for much of the work usually carried out by more elaborate and costly apparatus, and reads directly to 1/250 mm It can be supplied with an attachment to convert to a Michelson interferometer, thus giving a dual purpose instrument

Price Complete	**£190 0s.**
Attachment for converting instrument into Michelson Interferometer, extra	£45 0s
Polished wooden case, extra	£9 10s

Colour photography at
high speeds

The introduction of a new colour film that is faster than many black-and-white photographic materials opens up interesting possibilities for research workers The film, Kodak High-Speed 'Ektachrome' Film, has a speed rating of ASA/BS 160 .. BS log 33°.
Where coloured dyes are used as markers, in metallurgical analysis by flame propagation, in photo-recording where high-speed galvanometer traces overlap and need to be identified by colour, in photo-elastic stress analysis, in Schlieren photography, and in many other fields where high-speed transients and identification by colour go together, the unparalleled speed of this new colour film will be appreciated.

Kodak *high speed*
'Ektachrome' film

DIFCO ***microbiological reagents and media***

Bacto-Dehydrated Media for Microbiological Assay of
VITAMINS and AMINO ACIDS

These *media* contain all the necessary nutriments for the growth of specified test organisms for the microbiological assay of vitamins and amino acids except for the component under assay These basal media require only the addition of specified increasing amounts of the vitamin or amino acid being assayed to obtain a growth response which may be measured by acidimetric or turbidimetric methods for the construction of standard curves The vitamin or amino acid content of the material under assay is determined by adding appropriate concentrations of the test substance to the basal medium and comparing the growth response obtained with that of the standard

BACTO-RIBOFLAVIN ASSAY MEDIUM
BACTO-NIACIN ASSAY MEDIUM
BACTO-THIAMIN ASSAY MEDIUM
BACTO-PANTOTHENATE ASSAY MEDIUM
BACTO-B_{12} ASSAY MEDIUM USP
BACTO-CS VITAMIN B_{12} AGAR
BACTO-FOLIC ACID ASSAY MEDIUM
BACTO-PYRIDOXINE ASSAY MEDIUM
BACTO-BIOTIN ASSAY MEDIUM
BACTO-CHOLINE ASSAY MEDIUM
BACTO-CF ASSAY MEDIUM
BACTO-TRYPTOPHANE ASSAY MEDIUM
BACTO-LEUCINE ASSAY MEDIUM
BACTO-METHIONINE ASSAY MEDIUM
BACTO-LYSINE ASSAY MEDIUM
BACTO-ISOLEUCINE ASSAY MEDIUM
BACTO-ARGININE ASSAY MEDIUM
BACTO-TYROSINE ASSAY MEDIUM
BACTO-CYSTINE ASSAY MEDIUM

The *method* employed in carrying stock cultures of the test organisms and preparing the inoculum for microbiological assay is important The following media have been developed especially for carrying stock cultures and for preparation of the inoculum

BACTO-MICRO ASSAY CULTURE AGAR
BACTO-MICRO INOCULUM BROTH
BACTO-B_{12} CULTURE AGAR USP
BACTO-B_{12} INOCULUM BROTH USP
BACTO-NEUROSPORA CULTURE AGAR

BACTO-VITAMIN FREE CASAMINO ACIDS, dehydrated, is an acid hydrolysate of vitamin-free casein prepared especially for laboratories investigating microbiological assay of vitamins

Over 60 years' experience assures UNIFORMITY STABILITY · ECONOMY

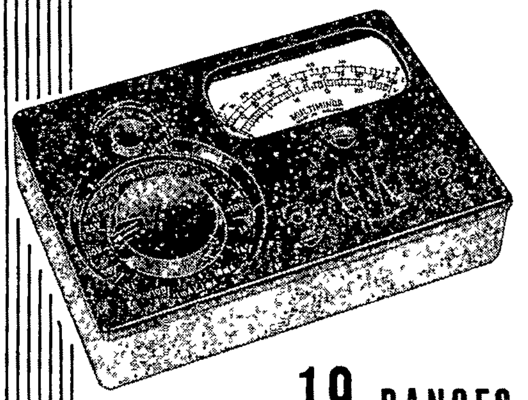
The

MULTIMINOR

A pocket-size instrument for the Laboratory worker



19 RANGES

THIS splendid AVO Instrument has been developed to meet a definite demand for a sturdy pocket-size multi-range test meter at a modest price, suitable for use on modern electronic apparatus as well as for radio and television receivers, motor vehicles, and all kinds of domestic appliances and workshop equipment.

Readings are obtainable quickly and easily on a very open scale, and range selection is by means of a robust clearly marked rotary switch of the characteristic AvoMeter type. Measurements of A.C and D.C Voltage, D C. Current, and Resistance are made by means of only two connection sockets.

Write for free illustrated leaflet

D C Voltage	A.C. Voltage
0— 100mV	0— 10 V
0— 2 5V	0— 25 V
0— 10 V	0— 100 V
0— 25 V	0— 250 V
0— 100 V	0—1000 V
0— 250 V	
0—1000 V	

Resistance	D C Current
	0—100μ A
	0— 1mA
0—20,000Ω	0— 10mA
0—2 MΩ	0—100mA
	0— 1 A

Sensitivity
10,000 ohms per volt on D C voltage ranges
1,000 ohms per volt on A C voltage ranges.

Accuracy
On D C 3% of full scale value
On A C 4% of full scale value

To meet special requirements, instruments can be supplied to a higher degree of accuracy for a small additional charge

Pocket Size 5⅝ x 3⅝ x 1⅝ inches
Weight 1 lb approx

"We strongly recommend"...

"The ever-widening field of Industrial Research requires more efficient and more accurate recording equipment, together with quicker methods of obtaining information.

"This demand has been satisfied by the production of our new highly-sensitive multi-channel galvanometer recorders of improved designs to give instantaneous records of electrical, mechanical and physiological phenomena

"We are indebted to Kodak Ltd who have produced a new "print-out" recording paper, called RP 12, which gives without processing, and in a few seconds, a visible image of good contrast.

"We strongly recommend Kodak RP 12 recording paper for use with our equipment both at home and abroad."

J Misrahi,
Research Engineer,
New Electronic Products Ltd.

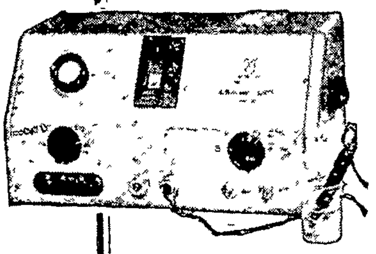
Conductance Bridge



CAT. NO. 11700

Pye Instruments

The Conductance Bridge is a mains operated instrument, designed for general laboratory work, including analytical and quality control determinations In addition to straightforward measurement of conductance, connections are provided for the comparison of two conductivity cells this is useful for finding the ratio between a standard cell and an unknown cell It is also possible to calibrate a number of cells against a known cell The range switch is arranged so that the circuitry is changed automatically to suit a comparison or an absolute measurement

Please write for full details on our range of chemical instruments—Argon Chromatograph, pH Meters, Conductivity Meters, Density Measuring Apparatus and Automatic Titrators.

NATIONAL PARKS AND NUCLEAR POWER STATIONS IN BRITAIN

IN addressing the Conference of National Park Authorities at Bakewell recently, then Minister of Housing and Local Government, Mr H Brooke, said that the national parks in Britain are not intended to be either museums without life in them or mere holiday resorts, and he emphasized once more the need to carry with us, in serving whatever purpose the national parks should meet, those who work and have their homes within those areas The vital necessity of public understanding and support has been clearly demonstrated during the first ten years of the operation of the National Parks and Access to the Countryside Act, but it has also been made abundantly plain that one of the major difficulties is that of finance The failure of successive Governments to provide the means has been the main cause of lack of progress, both through the impossible burden it has put on local authorities and by hindering or even preventing the work of educating public opinion

It would appear from his address to the Conference that the Minister was aware of much of this and it could be inferred from the tenor of his address that he had in mind the possibility of an amending or amplifying measure in the near future It is true he specified a clear conception of what the national parks are intended to be as a pre-condition of any fresh legislation, and it is obvious that the time is ripe for a good deal of clear and constructive thinking over this whole question of amenity, of the relation between national and local interest and the balance between various national interests which may or may not be irreconcilable

From this point of view alone, the report of the Forest of Dean Committee* merits attention This Committee was appointed in June 1955, under the chairmanship of Sir Thomas Creed, to review the situation in the Forest of Dean and, having regard to all existing rights and interests, to recommend such measures as are considered desirable and necessary to secure that the administration of the Forest, more particularly as regards the grazing of animals, may be adjusted to modern requirements The Forest of Dean is one of the ancient royal forests, second in area of woodland only to the New Forest, but although the forest does not lie in a national park area, it includes the first woodlands of the Forestry Commissioners to be designated a national forest park in England Its administration involves problems of reconciling such interests as afforestation, common grazing, and mineral and other development, which give the report of this Committee a profound interest to all concerned in the problems connected with the preservation of amenity and development generally

It is the recommendations of the report in regard to amenities, development and planning that are of chief interest here, although those relating to grazing, which occupy the greater part of the report, are of course equally important if damage either to sylviculture or features of special interest and beauty, which constitute the charm of the Forest and give it high amenity value, is to be minimized The report firmly opposes any proposal to carry out open-cast coal-working, in view of the grave effect such operations would have on the amenities of the Forest, and it will be noted that the National Coal Board on August 19 announced its intention of discontinuing such workings Likewise, the Committee recommends that the deputy surveyor, the officer responsible for the control of the Forest, should invariably be consulted when an application is made for a grant of land for mining or quarrying, or for the extension of the period of existing grants It is also recommended that the siting of overhead power lines should be planned to cause the least possible disturbance to the rural scene, and should be subject to the prior consent of the verderers

Many of the recommendations relate to matters of detail, such as the planting of the old colliery spoil heaps, the leaving of any disused railway track in a condition fit for other uses, the character of fencing and the immediate correction of such abuses of the open forest as the boiler works at Clearwell Meens (Sling) Tribute is paid to the valuable development work which has been done by the Development Association of the Forest of Dean, which should be encouraged to continue , but industrial development should be limited to that providing occupation for people who live in the immediate vicinity of the Forest and its surrounding villages and, so far as possible, should be concerned with the raw material of the Forest It is recognized that there is scope for further development of the tourist industry by providing more hotels, but the Committee recommends that the whole of the Forest should be declared an area of 'special control' under the Town and Country Planning Act, 1947, and particular attention paid to outdoor advertising. Provision of additional caravan sites and camping grounds and further facilities for car-parking and picnicing are also recommended, and the creation of additional points of view, with any necessary clearance of glades The Forest is fortunate in having soils universally recognized as favourable for the growth of the more exacting broad-leaved trees such as oak and beech, and it is recommended that the Forest should continue to be predominantly broad-leaved, and that the practice of placing tree name-boards where appropriate should be extended

The most cursory reading of the debate on national parks in the House of Lords on July 1 reveals the relevance of such details to the functioning, or even the existence, of national parks themselves, and there was a subsequent debate on nuclear power stations in the House of Commons on July 30 which was concerned specifically with the siting of overhead power lines This latter debate arose out of the decision to place a nuclear power station at Dungeness and to convey power, by overhead line or pylons, thence to Canterbury Other aspects of that decision are considered below, but the proposal to erect such overhead transmission lines from the power station to a sub-station at Lydd and to construct certain sections of an overhead transmission line from Lydd to a sub-station at Canterbury was also covered by the public inquiry on December 16–18, 1958 The Minister of Power, after consultation with the Minister of Housing and Local Government, announced on July 11 his intention to consent to the construction of the power station and of the overhead transmission lines

---

* Forestry Commission Report of the Forest of Dean Committee, 1958 Pp v+59+14 plates (Cmnd 686) (London H M Stationery Office, 1959) 8s net

The reports of the inspectors in charge of both these inquiries have been published, and that relating to the power station, a proposal which was uncompromisingly opposed by the Nature Conservancy, and its approval described by the Council for Nature as a scientific tragedy, merits close study by the scientist The debate on July 30, however, is of interest for the reply it drew from Sir Ian Horobin, then Parliamentary Secretary to the Ministry of Power, first defending the Government's siting policy and then explaining further the position regarding overhead transmission The Council for Nature had suggested that the Government should now review its policy of siting power stations on coast lands, as it would be impossible to continue indefinitely the siting of such stations away from built-up areas if any stretches of coast were to be preserved unspoiled

Sir Ian advanced no fresh arguments in defence of the present policy, though it is implicit in his statement that the policy should be reconsidered as soon as practical experience has demonstrated the extreme remoteness of any possibility of accident On the question of overhead transmission, he gave figures for underground transmission as of the order of £200,000 a mile, with a further 50 per cent to cover trenching and filling-in, and another £100,000 in certain circumstances to overcome instability due to the condenser properties of the cable He did not, however, disclose the basis of this estimate of, say, £300,000 a mile, which Mr W F Deedes had challenged, and, although he assured the House that the question of design is receiving very careful attention, in view of the strong objections to overhead transmission on amenity grounds and the misrepresentations of which the electricity boards have been guilty from time to time, it would seem somewhat unreasonable not to prepare independent figures from a source the impartiality and technical standing of which are alike above suspicion It was stated by Mr Reginald Maudling in a written reply in the House of Commons on July 13 that a decision on other parts of the transmission lines had been deferred, pending the examination of a possible alternative route which the Minister of Power had requested

The debate in the House of Lords preceded the announcement of the Minister's decision, but took place a few hours after work had been started on the Trawsfynydd nuclear power station—the outstanding example so far of the approval of the erection of a major industrial undertaking in the heart of a national park The debate was primarily on the ninth annual report of the National Parks Commission, and it was notable for an outstanding speech by Lord Birkett Lord Silkin, in opening the debate, had paid tribute to the value of the voluntary work now being done in the national parks, for example, by wardens, and in clearing away disfigurements, but after commenting that the Trawsfynydd decision was actually contrary to the opinion of the Ministry's own inspector, had stressed the need for adequate financial support from national rather than local sources Lord Silkin was strongly supported in all this by Lord Birkett, who commented that the Minister of Housing and Local Government should pay much more attention to the recommendations of the Commission, and that even as little as one-eighth of a penny a week per head of the population would suffice to preserve and guard natural beauty in our parks compared with the 11*s* a week at present required for national defence

The core of Lord Birkett's speech, however, did not lie in this plea for adequate financial support and publicity or even for the placing of the financial responsibility for a national interest where it properly belongs—on national and central rather than on local funds It was rather in his reasoned argument that the National Parks Commissioners should have adequate power This is partly a matter of appropriate administrative arrangements—national and not local—though Lord Birkett insisted on the need for local support and understanding, but it is much more a matter of recognizing that there are and must be occasions when amenity is the over-riding national interest, and on this point Lord Birkett supported the proposal to establish a special committee of the Privy Council as an appeal tribunal Over the years, he urged, a body of decisions would in this way be collected which would constitute a continuing guide, and with this, and certain modifications to the National Parks Act in respect of such matters as compensation, Lord Birkett seemed to think the situation might be met satisfactorily

While welcoming these speeches, the Earl of Dundee, in his reply on behalf of the Government, did not offer an assurance of legislation or meet the argument for the over-riding interest of amenity in certain circumstances Lord Silkin, indeed, dissociated himself afterwards from Lord Birkett's proposal for an appeal tribunal, but that merely strengthens the argument for adequate authority for the National Parks Commissioners themselves. Even more than the Trawsfynydd decision, that approving the erection of a nuclear power station at Dungeness demonstrates the inadequacy of the assurance of the Earl of Dundee that the Government is conscious of its duty to preserve and enhance the beauty of national parks, and that such problems will be carefully studied

The Dungeness proposal was strongly opposed on various grounds by the Kent County Council, the Botanical Society, the Royal Society for the Protection of Birds, the Council for the Preservation of Rural England, the National Farmers' Union, the Dungeness Fishermen's Association and others , but it is the opposition of the Nature Conservancy and the Council for Nature that is of main scientific interest, and even from the national point of view is most significant The Nature Conservancy did not oppose the proposal simply on the ground that the site chosen lay within a projected nature reserve Its opposition was based much more on the unique and irreplaceable permanent importance to science of the land in question, for which there is no adequate substitute in Europe As Mr E M Nicholson, director of the Nature Conservancy, explained in his evidence at the inquiry, the area, which is probably the most important stretch of new land added to England since 1600 and is the most suitable for tracing natural processes of coast-building as well as the largest cuspate foreland in the British Isles and probably in Europe, had long been treated throughout the world as a type example of a major coastal depositional feature It combines a history of major shore changes with records of other related changes such as river outlets, ports and settlements, and provides materials for research on the relations between the emergence of dry land and the variation of the shore-line Physiographers have made comprehensive studies of this area over a prolonged period, generally involving investigations of the shingle composition of the various ridges which appear on the Foreland There is still, however, a wide divergence of views on how and why this massive deposition of shingle at Dungeness occurs The presence of a power station on the site would probably prevent the continuance of the scientific work, while the destruction of the shingle ridges would destroy the evidence from which scientists could reach their conclusions

These studies, moreover, are of practical importance to coastal engineers, and their interruption would represent a great loss to the science of coastal studies A subsequent statement issued by the Council for Nature describing the decision as a scientific tragedy went so far as to assert that one result might well be the eventual disappearance into the sea of yet more villages on the east coast of Britain through lack of adequate knowledge of the means to check erosion Mr Nicholson emphasized that the site for the power station covered practically the whole of the remaining undisturbed area of shingle and coincided with the area where the recent ridges could be dated precisely from the nineteenth and twentieth century surveys Any large-scale interference with this shingle would thus make it impossible for any further studies on the ground to link the present to the past in uninterrupted sequence, and thus destroy for all time the area of scientific value to physiographers, sterilize the follow-up of past studies and prevent future work from which important results were anticipated and for which much fundamental material existed on the Dungeness site

Besides these reasons, which were fully supported by the Council for Nature, other objections to the proposal are minor Their force was fully admitted by the inspectors in charge of the inquiry, who recognized that the shingle ridges within the power station site would be destroyed , but though they thought that the work of the bird observatory at Dungeness might also be affected, they did not think that the area would be entirely impaired as a nature reserve, or that the work of botanists and entomologists would be upset Nevertheless, with some reluctance, the inspectors in their report recommended consent to the construction of the power station, and, as already noted, the Minister of Power has now given his decision accordingly

In announcing his decision, the Minister stated that he had had in mind the growth of the demand for electricity and the great importance of implementing the nuclear power programme He also pointed out that, even if there were no nuclear power programme, it would not be practicable to site new power stations on the coalfields, because of the very large quantities of cooling water required Nevertheless, he did not meet the essential point that from a physiographical point of view the Dungeness site is unique and its loss irreparable , alternative sites for power stations do exist and will ultimately have to be found This is indeed the key issue and might well justify the decision being described as something more than a national tragedy Until it is recognized that there are places where the national interest is primarily amenity or scientific, and where power development or even defence must be secondary, neither nature conservancy, national parks nor the planning of land development can have any real meaning It is of the utmost importance that the fullest possible use should be made of such reports as those of the Forest of Dean Committee, the National Parks Commission and of the Dungeness inquiry itself They demonstrate what is really involved and the price that has to be paid if in any part of this small island natural beauty, flora and fauna, or the scientific task of understanding and utilizing the natural resources of Britain are to be safeguarded against sectional and transient interests

THE EARTH AS VIEWED IN 1959

The Earth

Its Origin, History and Physical Constitution By Sir Harold Jeffreys Fourth edition Pp xvi+420+10 plates (Cambridge At the University Press, 1959) 75*s* net

GEOPHYSICAL research has proceeded so rapidly since publication of the third edition of Jeffreys's "The Earth" in 1952 that he decided to revise it Our information and hypotheses about the universe are changing rapidly, as any reader of *Nature* knows These hypotheses provide new ideas about the origin of the Earth and, consequently, change our notions of the Earth's history Use by geophysicists of electronic computers accelerates interpretation of new results in many fields of geophysics and permits rapid checking of hypotheses. Total funds available for geophysical research, even after the International Geophysical Year, are many times more than they used to be. New conclusions, many of them about properties of the oceanic crust of the Earth, mount rapidly and many of them are making apparently well-confirmed hypotheses obsolete. We have to consider the possibility that phase changes in silicates are responsible for discontinuities in the Earth which before have been attributed to sudden changes in material. Our hypotheses concerning the source of the Earth's magnetic field are in a state of flux. It has been found that the temperature inside the Earth may be greatly affected by radiation, especially across portions of the Earth's mantle. There are other examples for the fact that, at present, many of our hypotheses concerning the Earth are changing much faster than during any earlier period. Moreover, hypotheses about new fields in geophysics, for example on the outer atmosphere, are added. As a consequence, it is now impossible for one person to be expert over the whole of geophysics, as Jeffreys points out in the preface, and he does not discuss the problems mentioned above.

This rapid progress in geophysics requires that any geophysicist who wants to be up to date must consult new books and publications. Since Jeffreys's "The Earth" is the most used and best accessible book about geophysical problems, it is very gratifying that the fourth edition has been published. Every scientist working with problems which are discussed in the book will have to familiarize himself with the new edition. Among the problems, for which Jeffreys has revised earlier discussions, are some related to non-elastic processes. Unfortunately, many of these, while playing a very important part in geophysics, are still poorly understood even by specialists. Lack of such information affects investigations of the processes connected with body tides, variation of latitude, Love's numbers for the Earth and related problems, etc. Among other sections which have been revised by Jeffreys are those related to the temperature in the Earth and the structure of the upper portion of its mantle. New results concerning both have been published since the new edition was written. The suspected wandering of the Earth's magnetic poles is mentioned in the fourth edition, but in connexion with this and the related problem of continental drift, Jeffreys has still too many doubts about the underlying processes to give details. However, his books are always inspiring, regardless of whether the reader agrees with his conclusions or not. To summarize: study of the fourth edition of "The Earth" is strongly recommended to all scientists investigating problems related to physics of the Earth.

B. GUTENBERG

GEMMOLOGY

Gemstones

By G. F. Herbert Smith. Thirteenth edition, revised by F. C. Phillips. Pp. 560+27 plates. (London: Methuen and Co., Ltd., 1958.) 50*s.* net.

HERBERT SMITH'S "Gemstones" has been a standard book of reference on precious stones and a text-book for students of gemmology ever since its first edition appeared in 1912. In its ninth edition, published in 1940, it was considerably enlarged and still further additions were made to the tenth edition in 1949.

In the new edition Dr. Coles Phillips has shortened and simplified the chapters on crystal form and structure and the chapter on optical properties. Chapters on organic products—ivory, tortoise-shell, coral, jet and the resins—have been reduced and a short chapter on the formation of gemstones has been added, and also a very welcome chapter on the polarizing microscope.

An important change in the arrangement is made in that the distinction of precious and semi-precious stones is dropped. Instead of the old arrangement the principal gemstones are described in fifteen chapters and the others are collected in alphabetical order in one long chapter. This chapter contains descriptions of 25 mineral species that provide gemstones of varying merit and scarcity, including two new species discovered as gemstones, painite and taafeite, $MgBeAl_4O_8$. Sinhalite, $MgAlBO_4$, is described under olivine, with which it was confused until about 1957.

The book has been brought up to date wherever necessary and it has been possible to include a brief account of the successful crystallization of diamond in the laboratories of the General Electric Co., Schenectady, New York. Another piece of diamond news, concerning the famous Hope Diamond, was announced perhaps too late for printing in this book. This wonderful blue diamond of 44.4 carats, formerly the property of Mr. Harry Winston of New York, has now been presented by him to the Smithsonian Institution and is displayed in a special case in the newly designed mineral gallery of the National Museum in Washington.

In conclusion it should be added that print, paper and illustrations in this new edition are much improved and both author and publishers are to be congratulated.

W. CAMPBELL SMITH

TRENDS IN STATISTICS TEACHING

A First Course in Statistics

By Robert Loveday. Pp. xii+121. (Cambridge: At the University Press, 1958.) 8*s.* 6*d.*

Statistics

An Introduction. By Prof. D. A. S. Fraser. (Wiley Publications in Mathematical Statistics.) Pp. ix+398. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1958.) 54*s.* net.

THE flow of statistical text-books, which some years ago threatened to swell into a flood, has recently dwindled to a trickle; the appearance of two new books almost simultaneously is therefore a matter of some interest. But simultaneity is about the only thing these books have in common. The fact that they are aimed at different classes of students, in Mr. Loveday's case General Certificate of Education ordinary-level candidates, and in Prof. Fraser's case mathematical students in universities, accounts for only part of the difference. The main difference arises from a fundamentally different conception of what statistics is about.

Mr. Loveday is concerned throughout with distributions of empirical data and how to describe them. The concept of probability scarcely enters into the discussion; in the index, for example, the term is not even mentioned. No doubt Mr. Loveday has succeeded in presenting a clear and simple introduction to descriptive statistics Certainly he has collected together a set of exercises which will be useful in elementary teaching But it may be questioned whether, in the light of the developments of the subject that have taken place during the past thirty or forty years, this exclusive concentration on descriptive statistics is the best way of introducing the subject even at the most elementary level One would have thought that some of the time spent discussing measures of location and dispersion and similar matters could have been spared for an introduction to the more exciting topics of probability, sampling and inference

For the choice of subject-matter the author is perhaps not so much to blame as the General Certificate of Education examining authorities Mr Loveday must, however, bear the responsibility for cluttering up the student's mind with unnecessary and esoteric terms such as "ogive" in place of 'cumulative frequency distribution', "Galton graph" for 'scatter diagram', "historigram" for 'graph of a time series', "direct correlation" for 'positive correlation', and so on Those fortunate enough to become professional statisticians will never use these terms later in life Why should they have to learn them as beginners ?

It is hard to justify Mr Loveday's treatment of regression, as he confines his discussion of the fitting of regression lines to methods which are almost never employed in practice Why not give the student the formula for the least-squares coefficient ? The formula for the correlation coefficient is given in the succeeding chapter and this is certainly harder to understand, as well as to calculate, than the regression coefficient

Two minor points First, the definition of a random sample on page 93 as "one for which every member of the group has an equal chance of selection" is quite inadequate For example, a population of a hundred individuals could be divided into ten subgroups of ten in some systematic way and a sub-group picked at random, then every individual would have exactly one chance in ten of being picked but we would not have a sample of the kind the author is concerned with Secondly, the formula given for the normal distribution on page 107 should have the *n* deleted.

Prof Fraser's approach is completely different He begins with probability and probability distributions and never mentions empirical frequency distributions The question of what are the best measures of location and dispersion does not detain him at all: he plunges straight for the mean and variance and presses on at high speed Such an approach is quite intelligible in the light of modern statistical methods where the emphasis has shifted away from pure description to the fitting and testing of mathematical models Of course, in the book under review the treatment can be, and is, conducted at a fairly advanced level in view of the mathematical level of the reader for whom it is intended Nevertheless one would like to see a similar spirit abroad at all levels, however elementary

While reading the book one has the impression that among the author's guiding lights has been the wish to introduce students as early as possible to the ways of thinking about statistical problems that are customary among professional research workers It was particularly good to find a thorough treatment of orthogonal transformations, projections on to subspaces and pivotal reductions of the normal equations Once these basic ideas have been grasped the theory of multiple regression, the analysis of variance and covariance. and much else in statistical theory become straightforward

In spite of the book's merits it must be confessed that parts of it are likely to be found hard going by some students, particularly Chapter 7 on sampling from finite populations and its applications to the analysis of variance There are easier ways of deriving the formula for the variance of the mean of a sample from a finite population than that given on pages 136–7 Moreover, the misuse of the term "stratification' should not pass unmentioned Prof Fraser's "nested sampling" corresponds in sample survey terminology to multistage sampling, not to stratified sampling One feels that many of his results could be obtained more simply by current multistage theory than by the methods given in this chapter

J DURBIN

THE CULTURE OF CELLS

Cell and Tissue Culture

By Dr John Paul Pp viii+261+9 plates (Edinburgh and London E and S Livingstone, Ltd, 1959) 30*s* net.

IN 1959 it can be said that the technique of tissue culture is well established and widely applied, even on an industrial scale This claim could not have been made in 1949 Yet, more than fifty years ago the principles of cell cultivation outside the body were described and successfully demonstrated by Ross Harrison, and his work was energetically followed up by pioneer schools in the United States, Britain and elsewhere in Europe

As is strikingly apparent in Dr Paul's book, a new phase of confidence and application began about ten years ago, and cell and tissue culture to-day provides the following opportunities Mammalian and plant cells, adapted to culture conditions, can multiply indefinitely in chemically defined media When required, gram amounts of cells may be harvested after relatively short periods of growth All aspects of cell multiplication and development can be accurately determined and recorded Permanent cell strains, including a number of human origin, are available, and cultures can be sent safely to any part of the world

Clones are now readily established from single isolated cells, the chromosomes can be made clearly visible and their metabolic effects determined. Viruses may be detected and their pathogenicity investigated The metabolism of cancer cells and their response to treatment can be compared with the behaviour of normal cells, if these are freshly explanted from the body tissues

Dr Paul's up-to-date text will be invaluable to every newcomer to the technique and it will also be welcomed by experienced workers It describes lucidly all the technical aspects of the work, from the organization of a suitable laboratory (including such time-saving detail as a list of manufacturers) to the special procedures required for cell research The book is more than a laboratory manual, for it contains well-considered accounts of developments in cell research and a valuable store of references The only suggestion to be made is that future editions might include a section on the use of isotopic metabolites in tissue culture investigations

The reviewer does not wish to leave the impression that the cultivation of cells is now an easy matter and that there are no pitfalls The newcomer to the technique would be well advised to get some practical experience in an established laboratory As Dr Paul explains, his book is based to a certain extent on the instruction material of the Tissue Culture Association Summer School, which has in recent years provided a basic training for a few hundred individuals in the United States There is, as yet, no comparable scheme in Europe I Leslie

MEASUREMENT OF VALUES

The Measurement of Values

By L L Thurstone Pp. viii + 322 (Chicago University of Chicago Press , London Cambridge University Press, 1959) 56*s* 6*d* net

PROF THURSTONE, prior to his death in September 1955, was the world's greatest living psychometrist Psychologists, ever since leaving the philosophical fold, regarded the topic of values as out of bounds Most philosophers would probably be horrified at the idea of 'measuring' values In recent years, however, many scientists have realized that the concept of values is essential to science and that the greatest problem of the modern world is how to bridge the gap between technical knowledge and skill on one hand and knowledge of humanistic values on the other Some, however, regard the problem as insoluble or meaningless, forgetting that absolute laws are found neither in science nor in humanism During the last thirty years of his life Thurstone developed scientific methods which bid fair to bring social, moral and æsthetic values within the realm of experimental psychology He has ignored those interminable logical arguments concerning values

Human values are essentially subjective It was therefore necessary to establish a subjective metric, and a subjective unit of measurement which must satisfy the logical requirements of measurement as distinct from rank order This objective was reached by Thurstone by means of his law of comparative judgement which dates from 1927 Weber's law is concerned solely with physical measurements On the other hand, Fechner's law states the logarithmic relation between the subjective continuum and the physical stimulus continuum But Thurstone's law of comparative judgement is completely independent of any physical stimulus magnitudes It involves a new concept in psychophysics, namely, the discriminal error

The book has a preface by his widow, Mrs Thelma Gwinn Thurstone, herself a psychologist There is a selection of twenty-seven papers which have appeared in various journals

Part I of the book is an essay on "Psychology as a Quantitative Rational Science" where psychological concepts and strict mathematical formulation are emphasized Part II deals with "Subjective Measurement" Part III with "Attitude Measurement" Thurstone and his students were pioneers in researches on attitudes which are well known to psychologists everywhere They include such topics as prohibition, militarism–pacifism, and motion pictures

In the study of social attitudes the cognitive and the affective appraisals may be entirely independent For example, a group of people might dislike democracy but an examination might show that they did not know what they were talking about It is here pertinent to mention the views of the late Prof Flugel in his classic work on "Man, Morals and Society" (Chapters 1 and 16, 1948) where the tendency to change from orectic (moral) judgment to cognitive (psychological) judgement is one of the marks of moral progress It is true that the late Prof Reichenbach, the logical empiricist, in his "Modern Philosophy of Science" (1959) held that only a non-cognitive theory of ethics supplies an adequate explication of ethical utterances Prof Flugel, however, did not hold that orexis is supplanted by cognition Orexis still in the last resort supplies the goal at which we aim , cognition only guides us concerning the steps we must take to achieve that goal

It only remains to add that Prof Thurstone's book will long remain essential for all students of values

Ll Wynn Jones

CACTI

Die Cactaceae

Handbuch der Kakteenkunde Von Curt Backeberg Band 1 . Einleitung und Beschreibung der Peireskioideae und Opuntioideae Pp xvi + 638 + 35 tafeln 74 DM Band 2 Cereoideae (Hylocereeae—Cereeae (Austrocereinae)) Pp. xvii–xxiv + 639–1360 + 72 tafeln 87 DM (Jena . Gustav Fischer Verlag, 1958 and 1959)

THE first two volumes of this new 'handbook' to the Cactaceae provide a taxonomic treatment of the entire subfamilies Peireskioideae and Opuntioideae and reach the end of the 'subtribe' Austrocereinae of the 'semitribe' Austrocereae of the tribe Cereae, within the third and last subfamily Cereoideae In the opening key to the higher categories of the family the author recognizes a total of 220 genera, as contrasted with the 124 genera of Britton and Rose's comprehensive "Cactaceae" (1919–23) and the 41 genera of Alwin Berger's handbook to cultivated species, "Kakteen" (1929), in which *Rhipsalis*, *Cereus* and *Echinocactus* were treated in a broad sense with a large number of subgenera

Botanical exploration in South America, especially in Peru, eastern Bolivia and north-eastern Brazil, has yielded many new species to add to Britton and Rose's work, and it is good to have a new treatment with keys, descriptions and copious illustrations, some of them coloured Herr Backeberg has 57 species of *Tephrocactus*, 213 of *Opuntia*, 60 of *Rhipsalis* The elaborate system of categories in his classification of genera will not please everyone we are given, in descending order, *Unterfamilie*, *Tribus*, *Semitribus*, *Subtribus*, *Sippe*, *Untersippe*, *Gattung*, *Untergattung*, *Sektion* and *Untersektion*

The first volume begins with introductory chapters on the history of the Cactaceae in art and literature, on their uses by native tribes or in medical science, on classification, and on the maintenance of living collections In discussing cultivation, methods of grafting, etc , the author does not descend to the level of the small amateur grower, flat-dweller or floral decorator, but keeps strictly to the botanical and horticultural point of view This vast work, misnamed 'Handbuch', may well be open, like all big revisions, to much taxonomic criticism and, if only for that reason, will be indispensable to all serious students of Cactaceae N Y Sandwith

The Threshold of Space

The Proceedings of the Conference on Chemical Aeronomy, sponsored by the Geophysics Research Directorate, Air Force Cambridge Research Center, Air Research and Development Command, Cambridge, Mass , 25–28 June 1956 Edited by M Zelikoff Pp xi+342 (London and New York Pergamon Press, 1957) 105*s*

A MORE specific short title for this volume of papers on chemical aeronomy would be helpful The particular threshold of space is that of atmospheric photochemistry and spectroscopy While most of the papers are concerned with theoretical and laboratory researches, important experiments using high-altitude rockets, and some descriptions of phenomena produced by hypersonic flight, are also included

The book as a whole has both the shortcomings and the merits perhaps inevitable in a collection of individual papers There is a lack of coherence and the assumption of an extensive background knowledge by the reader However, the papers themselves, mostly by workers leading the field, are generally of a high standard Those dealing with theoretical and laboratory studies of photochemistry and spectroscopy related to the atmosphere of the earth, and of Venus, lead to accounts of rocket probing in the upper atmosphere Some of these papers relate to work such as the investigation of far ultra-violet radiation in the night sky, and the seeding of the upper atmosphere by sodium and nitric oxide which may well have heralded the opening of new branches of old disciplines

There is no doubt that both the problems and the experimental tools of hypersonic flight research will stimulate and facilitate further understanding of the physics and chemistry of the atmosphere The introduction of these aspects to the Conference proceedings is welcome Each paper is followed by a short verbatim discussion and a useful bibliography

The Insect Pests of Cotton in Tropical Africa

By E O Pearson, assisted by R C Maxwell Darling Pp x+355+8 plates (London Empire Cotton Growing Corporation and the Commonwealth Institute of Entomology, 1958) 40*s*

THIS book sets out to provide a vade-mecum for the study of the cotton pests of Africa, and is written both for "those concerned with the welfare of the cotton crop who are not entomologists" and for the field entomologist The main text occupies a little more than 300 pages of which the first fifty contain a succinct account of the cotton plant, *Gossypium*, its African environment, history, distribution and pests This section ends with an invaluable field key by means of which observed damage to the crop can be ascribed to its most likely cause, whether it be a fungus, an invertebrate or even 'big game' The rest of the book is devoted to comprehensive and critical accounts of specific pests which are grouped primarily by order, then, where convenient, by the parts of the host plant which they most usually attack This discussion is exhaustive yet always terse and gains much from the frequent and extended references to features of the environment relevant to the entomological data under discussion The authors do not hesitate to look outside Africa when they feel it will throw additional light on their subject and occasionally topics are treated almost in world-wide review The result is a satisfactory summary of current knowledge as well as a record of the authors' life-long personal experience

The book is well illustrated and indexed and is gratifyingly free from errors It may perhaps be worth noting that *Empoasca lybica* (de Bergevin) is not confined to Africa, as stated, but has been found also in Palestine, Arabia and in the Aden Protectorate, in the last of which it was reported on cotton A further natural enemy of *Empoasca facialis* Jacobi may also be added to those listed in the book, since there is in the British Museum (Natural History) collection a specimen of this leafhopper, from Serere, Uganda, which has been parasitized by a species of Dryinid W E China

Parasitic Animals

By Dr Geoffrey Lapage Pp xxiii+355 Second edition (Cambridge W Heffer and Sons, Ltd , 1958) 25*s* net

THE publication of the second edition of "Parasitic Animals" will be welcomed by many people, particularly those concerned with the teaching of parasitology Dr Lapage's treatment of his subject makes the book very readable and provides good background material for students It is, however, to be regretted that the author has not taken this opportunity to correct some of the errors of fact and to clarify some of the possibly misleading statements which appeared in the earlier edition I refer, in particular, to the perpetuation of such statements as that on p 107 that the male gametes of *Plasmodium* are "each about 15–20 mm long" and that on p 109 that the gametocytes of the same parasite "pass back from the mosquito to man they also enter man through the sucking tube and enter it passively, being unable to effect entry by their own efforts" On p 91 a slight alteration has been made to the original text but the inference to be drawn from the passage is still the same, that adult *Taenia solium* can normally develop in the intestine of the pig Reference might be made to several other points, but no doubt the observant reader will find these for himself The only major difference between the two editions is the inclusion in the second of a list of literature for further reading This is a useful addition, but it is disappointing to find that Baer's "Ecology of Animal Parasites", surely the most important book on the subject, has been omitted

C A Wright

Fundamentals of Papermaking Fibres

Transactions of the Symposium held at Cambridge, September 1957 Edited by Francis Bolam Pp x+487 (Kenley, Surrey Technical Section, British Paper and Board Makers' Association, Inc , 1958) 75*s*

THE salient features of this Symposium were summarized in *Nature*, 180, 1175 (1957) The 18 papers presented have now been published in book form, complete with illustrations, references and reports of the discussions The foreword quotes the view of Dr Otto Maas expressed in his concluding remarks at the Symposium, namely, that it had been a landmark in the science of paper making and had set a new standard for conferences in this field It is obvious that this book is indispensable to those directly interested in the subject Workers in allied fields, however, will also find in it much that is of great use and interest The inclusion of a subject index would have increased the value of the book for reference purposes Julius Grant

CYTOPLASMIC INHERITANCE

SMALL working conferences between European scientists particularly interested in genetics have been arranged from time to time, with the aid of grants from the Rockefeller Foundation to a small committee, composed of Profs M Westergaard, G Pontecorvo, B Ephrussi and D G Catcheside The fourth of these was organized by Prof B Ephrussi and held at Gif-sur-Yvette during April 3–7, 1958* On this occasion, a grant from the National Science Foundation made it possible to include five American geneticists, leaders in the study of cytoplasmic inheritance We are grateful indeed to these Foundations for the generosity which made possible such a successful and stimulating Conference

Aspects of cytoplasmic inheritance, especially in relation to development and differentiation, have been considered at two other recent conferences, one at the Royal Society[1] and the other at Gatlinburg[2] A considerable amount of the material considered at the Gif Conference has been covered in these and other publications

There are many examples of heredity which may be regarded as cytoplasmic or, more strictly, as extrachromosomal in determination, having regard to the possibility of there being intranuclear heredity which is not chromosomal Nevertheless, some expressed doubt as to whether any cytoplasmic heredity exists However, Dr R Sager, referring to the use of cytoplasmic male sterility in hybrid seed production, asserted that American geneticists had made a unique contribution to the solution of this problem Not only does cytoplasmic inheritance exist, but also it is commercially profitable and has been patented

Nevertheless, despite strong circumstantial evidence, the existence of chemical substances (plasmagenes), persisting permanently in normal cytoplasm in the same way that genes persist in the nucleus, has never been validated Indubitably, there is plenty of morphological diversity in the cytoplasm, as has been disclosed by electron microscopy Indeed, Drs W Bernhard and H K Mitchell were able to point to correlations between altered function and altered morphology

The criteria and the experimental means for the detection of extrachromosomal heredity received very careful consideration Formally, nuclear genes and plasmagenes are readily distinguishable, because in sexual reproduction nuclear genes follow precise segregational patterns based upon chromosomal mechanics while cytoplasmic genes do not The criteria of cytoplasmic heredity discussed, several or most of which have been shown to hold in many individual instances, include vegetative persistence , sudden changes in the trait (including reversibility) , absence of segregation at meiosis (therefore cannot be mapped on chromosomes) , cytoplasmic spread or infection , maternal transmission only or mainly , absence of relevant gene differences , diverse characters observed with the same nuclear genotype , character inducible by environmental agents , and selection effective during vegetative reproduction Nevertheless, these criteria are not sufficient means of recognizing cytoplasmic inheritance, *sensu stricto*, since many situations can generate this complex of symptoms

Among the numerous cases of supposed extrachromosomal inheritance there are some for which there is good evidence for extrachromosomal genetic information First among these and the most obvious are those in which microscopically visible structures in the cytoplasm are associated with the characters The chloroplast, together with the proplastid where there is a developmental sequence from the latter to the former, belongs here for one main reason When it is lost from a cell it cannot be reformed by the depleted cell It appears to be essential to have one in a cell before more can be formed This has been shown most elegantly by Deken-Grenson and Messin[3] A *Euglena* cell, descended from one treated with streptomycin to destroy its chloroplasts, can form new chloroplasts only if it still possesses at least one of these elements These experiments implicate the chloroplasts quite directly as possessing some information vital to their own reproduction

There is also evidence of mutability on the part of the chloroplasts, such as is provided by the differences shown in Renner's classical experiments However, the question is still unsettled as to whether it is the chloroplast or some other non-chromosomal component which is responsible[4] The kinetosomes and centrioles may likewise be classed here, though the evidence is less decisive The kappa, pi, mu and similar particles, rich in deoxyribonucleic acid, found in Ciliates, as well as other intracellular symbionts, are further examples, though these bodies are not normal to all or indeed to very many cells

Secondly, there is a considerable group of cases for which the evidence points to extrachromosomal sources of genetic information but for which there are no microscopically visible structures in the cytoplasm which show correlated behaviour The determinant of streptomycin resistance in *Chlamydomonas*[5] is a clear case The commercially important self sterilities in maize appear to belong here, as also do the plasmon traits studied particularly by German geneticists[4] Srb[6] has described an interesting case

---

* The Conference was organized in seven sessions, following a general introduction by Prof Ephrussi

(1) Phenomena of Integration of Particles of Probably Extraneous Origin F Jacob and E Wollman on "Lysogeny and Zygotic Induction", Ph L'Heritier on "Carbon Dioxide Sensitivity in *Drosophila*", D Lewis on "Lysis in the Fungus *Coprinus lagopus*", G Magni on "Sex Ratio in *Drosophila*", A Ohanessian on "Genic Control of the *Drosophila* Virus", T M Sonneborn on "Kappa and Paramecin"

(2) Normal Cytoplasmic Components endowed with Genetic Continuity R Sager on "Extrachromosomal Heredity in Green Plants" W Bernhard on "Fine Structure of Cytoplasm"

(3) General discussion of preceding subjects H S Sharpe on "Closed and Open Systems of Extranuclear Inheritance in *Aspergillus*", H Laven on "Interracial (Geographical) Crosses in *Culex pipiens*"

(4) Cytoplasmic and Environmental Effects on Nuclear Information D L Nanney on "Mating Types in Protozoa", G Rizet and D Marcou on "Barrage and Senescence in *Podospora*", G Sermonti on "Cytoplasmic Inheritance in *Penicillium*", A M Srb on "Effects of Mutant and Normal Cytoplasms on *Neurospora* Phenotypes", J A Roper on "Acriflavine-induced Cytoplasmic Variants of *Aspergillus*"

(5) Flux Equilibria J Monod on "Inducible Permeation Factors and Cellular Memory in *Escherichia coli*", G H Beale on "Antigenic Types in *Paramecium*"

(6) Extrachromosomal Factors in the Synthesis of Respiratory Enzymes B Ephrussi on "Respiratory Deficiency in Yeast", P Slonimski on "Determination of Specificities of Respiratory Enzymes", H K Mitchell on "Biochemical and Genetic Aspects of Poky *Neurospora*", A B Pardee on "Genotypic Change and the Rate of Enzyme Induction"

(7) General discussion T M Sonneborn "Summary of the Conference",

Other participants were M Westergaard, J Scheucroun, G Pontecorvo, N Plus, D G Catcheside and G Brun in *Neurospora* which could belong here. A character SG (manifested as slow initial growth) appeared in *N. crassa* following acriflavine treatment and was inherited maternally. By repeated backcrossing, nuclei of other species could be introduced into SG cytoplasm and it was shown that a gene expressed as aconidiate in *N. sitophila* was expressed as conidiate in SG cytoplasm. Formally, one may describe this as a cytoplasmic suppressor of a nuclear gene, just the converse of the genic suppressor of poky in *Neurospora*[7]. The impressive feature is the prolonged propagation of the cytoplasmic factor unchanged, whether or not it has this particular expression. Also included here may be the general 'pattern of organization', by which the information given by the nucleus to the cytoplasm is marshalled. The cytoplasmic reproduction of enzyme specificity may be an aspect of this.

The petite mutants in the yeast[8] and the poky ones in *Neurospora*[9] surely belong to one of the above two groups, indeed to the first if mitochondria are implicated. It is interesting to note that electron microscopy of poky *Neurospora* shows slightly abnormal mitochondria in conidia, and grossly altered mitochondrial material in the hyphæ.

Thirdly, the transmission of virus or provirus is the mechanism in another group in which the inheritance can be traced to a particle by various means. The situation in lysogenic bacteria forms a model. As Jacob and Wollman[10] have shown, prophage in *E. coli* is closely integrated with the bacterial chromosome, though it is not a part of its linear structure. The presence of prophage does not alter the genetic distance between markers in its region of integration, despite that it covers a considerable part, about one-fiftieth, of the map. The phage is perhaps synapsed with the bacterial chromosome, but its material is not identical with the genetic material of the bacterium, for neither can add to the other. There are various ways in which a system with or without a virus or provirus could exhibit apparent extrachromosomal heredity.

The virus and provirus scheme applies very well to the case of sensitivity to carbon dioxide in *Drosophila*[11]. The resistant flies, free of σ virus, seem equivalent to non-lysogenic bacteria. The non-stabilized σ condition, which is not transmitted by males, would be equivalent to infected bacteria. The stabilized condition, in which males may transmit σ virus to offspring to give the unstabilized condition, would be equivalent to lysogenic bacteria, with the virus integrated, perhaps to a chromosome. Fourthly, the ρ condition, in which sensitivity develops with ageing, but only in a proportion of the flies, would correspond to defective virus. The stabilized ρ condition would be equivalent to defectively lysogenic bacteria.

It therefore appears that elements exerting a hereditary influence may be present alternatively in the nucleus, associated with a particular part of the chromosome, or free in the cytoplasm. That the elements known to behave in this way happen to be pathological could simply be a consequence of the presence and action of normal ones being undetectable. Cellular differentiation and consequent cytoplasmic inheritance in cell lines could be due to controlled movement, between nucleus and cytoplasm, of controlling elements. Indeed the liaison between nucleus and cytoplasm seems to require a system of directors, messengers and executives.

In a further class of cases, the genetic information is in the nucleus, but the different states of the cytoplasm act epistatically. Here may be placed the permease system induced in *Escherichia coli* by thiomethylgalactoside[12], the serotypes and the mating types of *Paramecium*[13]. The complete range of potentiality in the case of the *Paramecium* characters is determined by the nucleus. The individual characters, as is particularly clear in the case of the serotypes, depend for their specificity upon the genes themselves. Extrachromosomal factors intervene only in determining which of the possibilities is expressed in a given cell. The particular expression in a cell determines, subject to revolutions caused by environmental changes, what shall be expressed in its descendants. This epistasis is cytoplasmic in the case of the serotypes. In the case of the mating types it is primarily in the macronucleus, but secondarily there is transmission through the cytoplasm in *Paramecium aurelia* of group *B*[14]. The cytoplasm of a differentiated cell directs the differentiation of an undifferentiated nucleus put into it. In *Escherichia*, competence to respond to the inducer is dependent upon the nuclear genotype. Thus, in both *Paramecium* and *Escherichia* the extrachromosomal control overlies the chromosomal. Whether it has the conditional permanence of a steady-state system, or some other relatively impermanent feature of cytoplasmic architecture, or the permanence of a plasmagene, is unknown.

Many cases of apparently extrachromosomal inheritance cannot yet be classified with the least certainty with respect to probable mechanism. A few appear likely to be nuclear determined and to involve superimposed controls, namely, lysis in *Coprinus lagopus* (Lewis, D., unpublished work), certain slowly growing mutants in *Penicillium* (Sermonti, P., unpublished work), and the mycelial modifications induced in *Aspergillus* by acriflavine[15]. This leaves the barrage and senescence phenomena in *Podospora*[16], the dual phenomenon in *Aspergillus glaucus* (Sharpe[1]), the racial differences in *Culex pipiens*[17] and the sex-ratio trait in various *Drosophila* species[18]. Each of these permits of two or more different kinds of interpretation.

To some extent, recognition or denial of the existence of cytoplasmic inheritance depends upon one's definition of heredity. Some would restrict the property of being hereditary to chemical elements which persist permanently in the cytoplasm, in the same way that genes persist in the nucleus. Alternatively, it may be held that any difference in trait which is propagated under effectively the same set of conditions through vegetative or sexual reproduction, or both, is a hereditary difference. The transmission of the special property of each to its descendants constitutes heredity. This latter view regards the phenomena of development and differentiation as involving genetic changes, generally extrachromosomal, which are then maintained by a hereditary mechanism.

On this view, the difference[12] between two cultures of *Escherichia coli* growing on 10^{-5} *M* thiomethyl galactoside, one of which has been primed for a short time with 10^{-3} *M* thiomethyl galactoside and the other not, is a hereditary difference. Here the thiomethyl galactoside in higher concentration has acted as an inducer of a permease, which will then bring thiomethyl galactoside into the cell from a weaker solution unable itself to initiate the induction. Such a steady-state system would perpetuate itself under suitable conditions, without involving the self replication of particles. However, much turns upon what is meant by a particle and by self replication. There can be little doubt that permease is particulate and macromolecular in nature. The maintenance of the steady-state system in a growing culture requires a continuous supply of inducer (or substrate) in order that more permease may be produced. Somehow, between them, and of course in the environment of the living cell of which they are a part, the system of inducer and permease holds information needed to make more permease, that is, to convert or mould some other cell product to its own image. The production of this other cell product is under the control of the rest of the cell, including the genetic information of the nucleus. Thus underlying the steady-state system in this particular case is the genetic competence of the lineage of cells to respond in the particular way to the presence of the inducer.

The thiomethyl galactoside permease system has another interesting property. When the kinetics of induction are studied[19] under conditions of continuous culture, the degree of adaptedness in the culture rises linearly with time (measured as generations) if a low concentration of thiomethyl galactoside, just able to cause induction, is used. In such a culture, a proportion of the cells is fully induced or adapted, the remainder being quite unadapted. There are no intermediates, or rather the state of intermediacy is too transient to detect. Once some permease has been formed in a cell, a full complement of it is rapidly acquired, presumably according to a logistic curve. Thus the stable states are discontinuous.

Such a steady-state system has some of the attributes of genetic material, but may be thought to differ from genes and plasmagenes in certain essentials. Especially it is inherited only so long as it is expressed. Secondly, if lost it can be regenerated by a simple manipulation of the environment, provided the genetic basis is still present in the nucleus.

The contrary view is that heredity is dependent upon certain homœostatic material and that various different expressions of it, no matter how persistent, do not differ in a truly hereditary manner. Nanney[20] distinguishes these two aspects as 'genetic' and paragenetic or 'epigenetic'. As it was believed that paragenetic is etymologically unsound, 'epigenetic' was suggested, although this word is used for embryological theory and may be unacceptable for that reason. Indeed, Lederberg[2] avoids the difficulty by going to the extreme and speaking of 'nucleic' and 'epinucleic'. Nucleic information is defined as that depending upon the sequence of nucleotides in a nucleic acid, while epinucleic information is expressed as an aspect of nucleic acid configuration other than nucleotide sequence or in associated materials, such as polypeptides or polyamines. It may also reside in molecules or reaction cycles not directly connected with nucleic acid.

Whether this particular differentiation between the two levels of genetic information will stand the test of time, it is clear that the distinction is not only provocative but also the crystallization of ideas towards which many have struggled. No other biological system, short of the whole organism, approaches the properties of nucleic acid in conveying information, or equally justifies the supposition that it carries the bulk of germinal genetic information. A minor part of the genetic information, the plasmagenes, is presumably extranuclear nucleic acid. Likewise, the functionally active ribonucleic acid in the cytoplasm may carry nucleic information. Equally, if nucleic acid conserves genetic information, it is difficult to see how cellular differentiation could be determined by systematic gene mutation, that is to say, by systematic alteration of nucleotide sequences.

The epinucleic spheres of action may be extranuclear, like the steady-state systems, or nuclear, and even involve the chromosomes. There is now strong circumstantial evidence of differentiation occurring in nuclei, so that the nuclei of different tissues come to have different heritable potentialities[21]. This may be reflected in differences visible in polytene chromosomes, as in *Chironomus*[22], as well as the substitution of histone for protamine in different nuclei, but the differences could also reside in nucleoli. The local variations in behaviour of the chromosomes may sometimes be seen as intense deoxyribonucleic acid metabolism at certain regions[23]. This kind of intranuclear differentiation appears to be the basic step in the expression of mating types in *Paramecium*. Such changes could be stochastic, but it seems likely they are directed in some way not, as yet, understood. The interesting occurrence of paramutation[24] at the *R* locus in maize and the controlling elements described by McClintock[25] seem to offer models of particular systems, as also does lysogeny.

In considering cytoplasmic inheritance *sensu stricto*, we are therefore faced with the problem of distinguishing hypothetical extranuclear nucleic material from extranuclear and intranuclear epinucleic phenomena. It must be conceded that completely sufficient criteria for achieving this have not yet been recognized. It cannot yet be said whether there are macromolecules which persist permanently in the cytoplasm in the same sense as genes persist in the nucleus. Chloroplasts and mitochondria are candidates only in the same sense that the nucleus as a whole is nucleic information. The critical point would be reached if the physical bases of non-chromosomal hereditary systems, possibly nucleic or epinucleic, could be identified. In any event, whether or not we speak of epinucleic phenomena as constituting heredity, clearly they can determine the inheritance of a particular character through a considerable lineage of cells.

A complete understanding of the function of the cytoplasm in heredity is likely to involve an understanding of the nature of gene action and replication. Gene replication is generally thought to be by some kind of template mechanism, a pre-existing structure organizing smaller units to form a replica of itself. The various modifications of this basic idea need not be considered here; all would lead, theoretically, to the duplication of the gene material, most probably deoxyribonucleic acid. The heterocatalytic property of the gene, in directing functions elsewhere in the cell, may well be through the medium of replicas of itself, or of translations in a chemically different form, perhaps ribonucleic acid or protein or both. The precise activity of these will depend upon how they are integrated with the rest of the cell. If, as seems probable, they are originally filamentous, like the gene material of the chromosomes, their activity will depend upon how and where they are folded into the structure of the cell. In this respect they are likely to be influenced by the existing architecture of similar and associated units, as well as by the presence or absence of regulating substances, such as inducers or repressors. Thus, the organization for expression appears likely to involve another sort of template or mould mechanism, an architectural plan for using the unit bricks produced by the genes[26] In more specific terms, Mitchell (unpublished work) has suggested that the cytoplasmic information is carried by the proteins and that these co-operate with ribonucleic acids, carrying the information from the nucleus, in forming ribonucleoprotein templates which direct the formation of enzymes Neither system alone possesses all the information needed for the building and functioning of a cell Both involve heredity, though probably the cytoplasmic system has a lesser degree of permanency

The expression of the nuclear products has, therefore, been shown quite often to require extragenic information Knowledge of the exact nature and mode of action of the latter is highly important for understanding the functioning of the living cell While it is possible that extragenic information may be carried in a variety of ways, it may be a more economical hypothesis to suppose that it lies in one type of material capable of interacting directly with products from the nucleus In this respect, protein architecture in all its variety seems a more plausible candidate than does a system of alternative steady states, such that the functional one in the cell suppresses the action of all genes having alternative functions The latter encounters severe difficulties in view of the great variety of specific inhibitions, acting in a huge range of combinations, that would be required This is the major obstacle to interpreting, for example, the serotypes of *Paramecium aurelia* as mutually suppressive systems of steady states

THERMONUCLEAR RESEARCH IN GREAT BRITAIN

THE present state of the research programme, both theoretical and experimental, on the subject of thermonuclear fusion was the main topic at a recent two-day meeting of the Physical Society held at the Imperial College of Science and Technology, London, during September 17–18 The conference was attended by representatives from most of the major centres in Britain, and formed an interesting continuation of the meeting of wider scope at Uppsala in August It is an indication of the present high level of activity in this work that, with the exception of review papers, little duplication of material occurred

The main session was devoted to contributions outlining the research programmes at the various laboratories, universities and research institutions

Activity in Great Britain has largely centred around the toroidal pinch devices *Zeta* and *Sceptre*, where the discharge is confined by the magnetic pressure produced by the toroidal current in the discharge itself Papers by M G Rushbridge (Atomic Energy Research Establishment, Harwell) and A A Ware (Associated Electrical Industries, Ltd, Aldermaston) showed that steady progress is being made in understanding the complexities of this type of discharge In *Zeta*, experiments on the magnetic field distributions in the torus have led to a suitable choice of dimensionless parameters which can be used to characterize the discharge and compare it with various models In *Sceptre*, much effort has been put into the measurement of ion- and electron-temperatures by spectroscopic means, and the electron temperature at $2-3 \times 10^5$ °K has now been checked in several ways Similar magnetic field distributions to *Zeta* are obtained, in which the magnetic field lines within the plasma are helices of constant 'wavelength' around the torus and the mutual phase relationship of which is the same at all points This has led to a tentative explanation of the results in terms of the kind of helical instability found in some American experiments on large-size linear discharges The energy balance in these discharges is also being examined as part of a search for an explanation of the low electron temperature, but the energy losses have not yet been completely accounted for

The work of the group at the Atomic Weapons Research Establishment, Aldermaston, described by K W Allen, is in an interesting state of development The original very fast linear pinch-work which was pioneered at the Establishment is now being supplemented by an apparatus similar to the American *Scylla* at Los Alamos, which also requires a condenser bank of very low inductance In these experiments a circumferential electric current is induced in a cylindrical plasma and causes rapid compression. G B F Niblett showed some very clear streak photographs of an end-view of this compression in which it is seen to be quite a complex process with

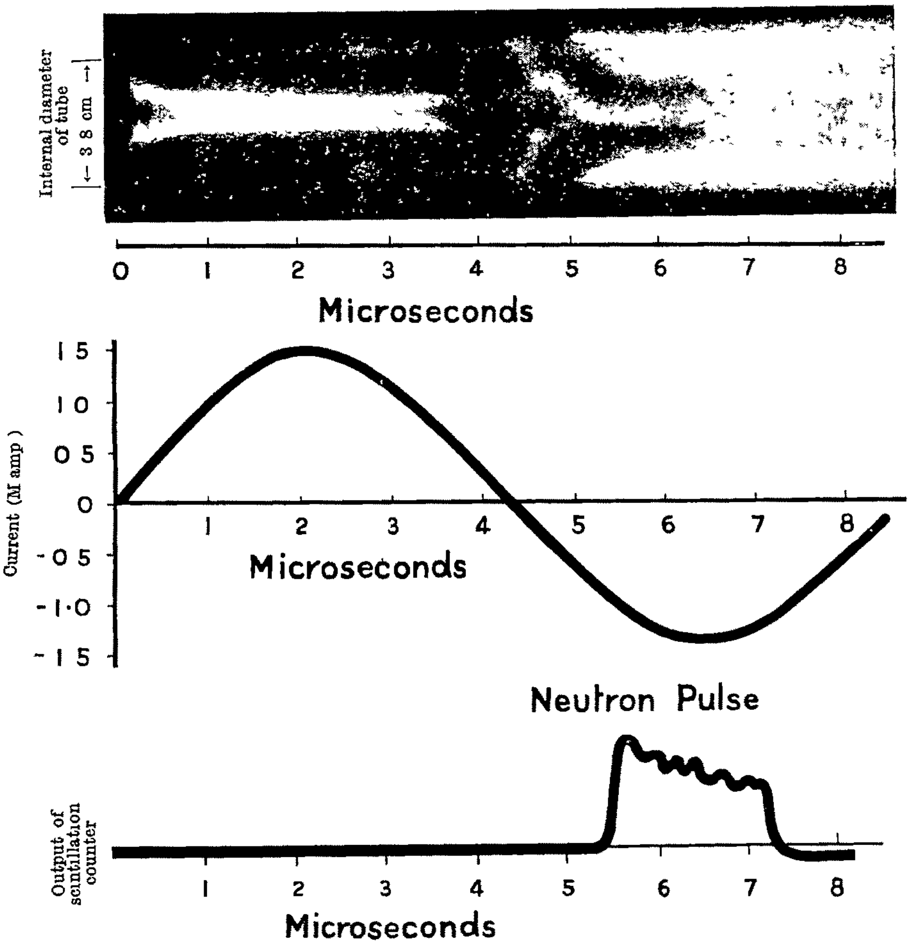

Fig. 1. Streak photograph of a discharge in deuterium with current wave-form and neutron output. (Atomic Weapons Research Establishment, Aldermaston)

marked differences between the phenomena in the first and second half-cycles (Fig. 1). The differences are ascribed to the presence of magnetic fields retained within the plasma. Neutrons are emitted, as in *Scylla*, in the second half-cycle of the discharge and the origin of these is being studied.

A further interesting possibility was mentioned which, though experimentally difficult, is now being actively considered. This is to fire a beam of fast-moving neutral atoms into the kind of magnetic bottle developed for *DCX* in America and *OGRA* in the U.S.S.R. The injection of neutral atoms instead of molecular ions should lead to better confinement, since the former can penetrate without deflexion into the centre of the apparatus before being ionized and trapped. The technical difficulties in producing such a beam must be overcome, but this can be done as an independent problem.

The work at the Imperial College of Science and Technology reported by R. Latham is based on the simplest form of linear discharge. In this the disadvantage of electrodes is compensated for by the low inductance of the tube, which is essential for rapid compression, and by the simplicity of the geometrical arrangement which allows the discharge to be viewed both from the side and the end. The first constriction, which appears as a very narrow column of high-temperature plasma (Fig. 2), the subsequent growth of instabilities (Fig. 3) and the appearance of impurities from the walls at a later stage have all been studied by means of careful photographic techniques. The use of metal liners to reduce the effect of impurities has been tried with some success.

Two papers from industrial laboratories completed the programme. P. C. McNeill, of the British Thomson-Houston Co., Ltd., Rugby, described an attempt to influence the properties of an electrical arc by placing a pair of magnetic mirrors along its length. L. A. King described work at the Electrical Research Association Laboratories, Leatherhead, where a persistent and successful attack has been made over a period of years on the thermal properties of gases as applied to the formation of cores in high-current electric arcs. The facilities at Leatherhead are now being applied to a study of the high-current vacuum arcs in use in the *DCX* machine.

The three subsequent sessions are concerned with diagnostic methods, theoretical problems and the role and use of shock waves in thermonuclear work.

In the first of these, the emphasis was on time-resolved photography and spectroscopy, which are necessary for a study of pulsed discharges of short duration. Single-shot photography with Kerr cells and image converters has been the subject of much research, and exposure times of 0·1–0·2 μsec. are now in common use. Time-resolved spectra taken at the Atomic Weapons Research Establishment by A. H. Gabriel have shown the sequence of growth and decay of lines in a linear discharge which is completed in 3–4 μsec. Such spectra are beginning to give evidence on how near these discharges are to thermodynamic equilibrium. The consequences of lack of thermodynamic equilibrium, its effect on temperature measurements and recent developments in measurement technique in the range 10,000–50,000° K. were discussed in a review paper by H. Edels (University of Liverpool).

Theoretical work on hot plasmas covers a refreshingly wide range of topics and illustrates the close connexion between plasma physics and astrophysics. It may well turn out that thermonuclear experimenting will produce ideas on phenomena in the solar atmosphere, for example, solar prominences and

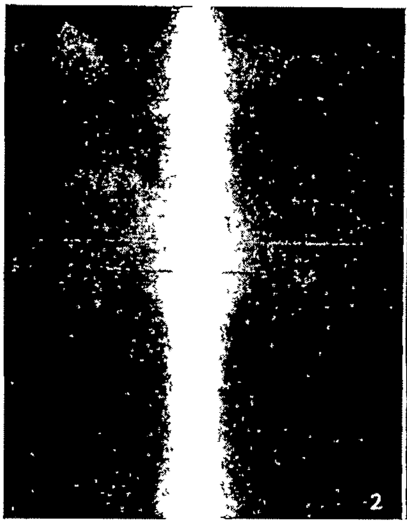

Fig 2 Side view of linear discharge taken at the time of maximum constriction (Imperial College of Science and Technology)

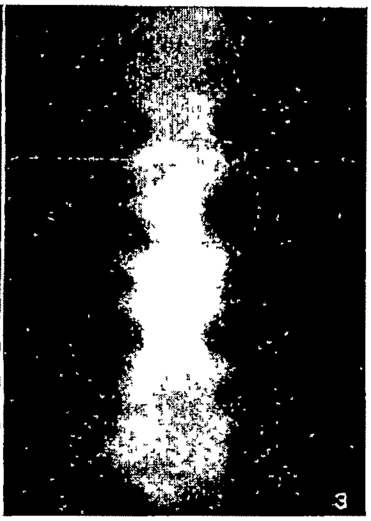

Fig 3 Side view of linear discharge showing the unstable plasma boundary (Imperial College of Science and Technology)

flares, and in a wider context on the generation of cosmic rays This is not surprising when it is remembered that a star is a naturally occurring thermonuclear reactor, and stellar atmospheres have much in common with laboratory discharges Indeed, astrophysicists have been studying thermonuclear and magneto-hydrodynamic problems for many years, long before these subjects became important in the laboratory

Problems common to astrophysics and discharge physics were discussed by Prof V C A Ferraro (Queen Mary College, London) in a contribution on current-bearing streams from the Sun, by Prof T G Cowling (University of Leeds) on mechanical effects of the interaction between a plasma and a magnetic field, and by Prof H Bondi (King's College, London) on "Magnetostatics", with the emphasis on astrophysics

Among the other theoretical papers, one by W B Thompson (Atomic Energy Research Establishment, Harwell) contained in outline a derivation of the transport coefficients of ionized plasmas which avoided the arbitrary introduction of the Debye length This was replaced by a statistical treatment of the potential fluctuations, related to the theory of electrical noise It is encouraging that the expressions previously used are in agreement with those derived by the new method A paper by M G Haines (Imperial College) considered the skin effect and showed how the familiar skin current of alternating current theory occurs only on the rising part of the wave-form of the current in a transient discharge As the current decays, the theory predicts an inverse of the skin effect with the current becoming a maximum at the centre of the discharge, and even negative at the outer surface This could in principle lead to the surface layers being violently ejected from the discharge R J Tayler (Atomic Energy Research Establishment, Harwell) has extended his stability calculations on a cylindrical discharge to include the effect of the transport coefficients He has considered a cylinder of incompressible plasma with given combinations of the coefficients of electrical conductivity and viscosity Diagrams showing the growth-rate of the $m = 0$ (sausage-like) and $m = 1$ (helical) perturbations as a function of their wave-length indicated the presence of unstable regions in both cases

The last session was on shock waves in gases These have relevance to very hot plasmas because of their use in heating the gas on one hand, and because of their appearance as a result of rapid magnetic compression on the other

In two papers, K Dolder (Atomic Energy Research Establishment) and H J Pain (Imperial College) reported on the use of shock-heated argon to find values of the non-dimensional parameter, analogous to the Lundquist number, which governs the magnitude of the interaction between a plasma and a magnetic field When plasma flows through the magnetic field of a short axial coil and interaction does occur, a characteristic pattern in the downstream gas is observed similar to that obtained with an annular constriction in the shock tube

Measurements of electrical conductivity in shock-heated argon have been made by A von Engel (Oxford) using the potential developed between two probes as the plasma moved between them in a transverse magnetic field In this case the requirement of electrical neutrality lowered the conductivity to that associated with the ions P Smy (Imperial College) reported on electrical conductivity measurements in which an azimuthal current was induced in the moving plasma as it passed through axial magnetic field coils The induced current was detected magnetically by a search coil In this instance the current flows in a closed loop in the plasma and the electronic conductivity is appropriate In both cases the results were in good agreement with the values expected theoretically

A critical account of the use of shock-wave heating as a first stage in obtaining a thermonuclear plasma was presented by J K Wright (Atomic Weapons Research Establishment, Foulness) He considered electromagnetically driven shocks and discussed

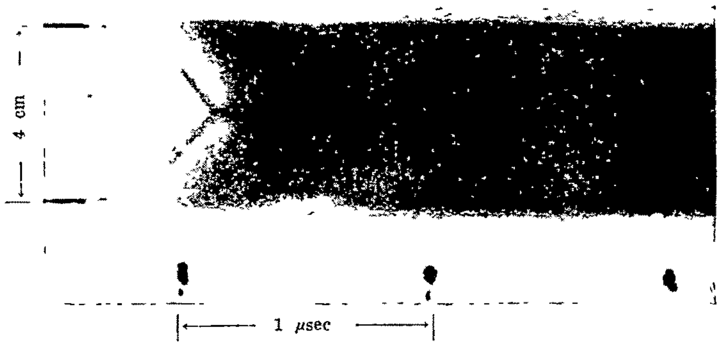

Fig 4 Streak photograph showing two colliding shock waves The shock waves move vertically and time increases from left to right (Atomic Weapons Research Establishment, Foulness)

theoretically the limits imposed by residual inductance and the requirement that the thickness of the shock-front be kept small compared with the size of the apparatus After being heated by the shock wave, the plasma was assumed to be subjected to a further stage of adiabatic compression Experiments on electromagnetically driven shocks are continuing, and an interesting streak photograph was shown of two colliding shock waves produced by this means (Fig 4) Papers were presented by D L Schultz and K C Lapworth (National Physical Laboratory, Teddington) dealing with microwave reflectivity of shock-heated plasma and with temperature determination by the method of line reversal The reflexion of shock waves from a region of high magnetic field was examined theoretically by E J Morgan (Engineering Laboratory, University of Cambridge) as a basis for future experiments

It is evident from both the Uppsala Conference and this meeting that the approach to thermonuclear research has changed since the Geneva Conference a year ago The emphasis has moved from a few projects requiring large-scale equipment to many simpler experiments designed to clarify the basic principles of plasma physics It is obvious now that in such matters as stability, plasma oscillations, energy-loss and transport processes, there is much more to be learnt The lack of immediate success of the larger machines, therefore, though disappointing is by no means without its compensations It will result in plasma physics being put on a firm basis in which the fully ionized gas will take its place with the other states of matter as leading to an accepted branch of physics This is a task for the future, and one which can be shared by many smaller groups with modest resources The outcome will undoubtedly lead to important developments of wide application both in pure science and in technology, with the generation of thermonuclear power as the final target

PUGWASH INTERNATIONAL CONFERENCE OF SCIENTISTS

STATEMENT ON BIOLOGICAL AND CHEMICAL WARFARE

THE fifth in the series of Pugwash Conferences of scientists, aimed at assessing the dangers to humanity arising from developments of modern science and technology, met in Pugwash, Nova Scotia, during August 24–29, as guests of Mr Cyrus Eaton The purpose of the Conference was to assess the potentialities of chemical and biological agents as weapons, and to explore possible means for preventing their production or use in war

The subject of chemical and biological warfare has been shrouded in official secrecy For years, large projects have existed in several countries with the stated purpose of developing means of defence against such weapons We have no direct information about the results of these projects, but inevitably they increase the efficiency and destructiveness of various types of biological and chemical weapons, and result in the development of new techniques Judging from the number of technical workers involved in such projects and the money expended, much knowledge related to the production and delivery of micro-organisms for war purposes has probably been gained Moreover, unsupported statements appear which suggest that such weapons have enormous lethal or incapacitating effects against man, can destroy plants and animals, and have advantages under certain conditions of war Recently, a concerted effort appears to have been made to suggest that these weapons are more 'humane' than other means of warfare

We have discussed the general nature of such weapons as well as the properties of the individual agents and their methods of delivery, and have compared them with other weapons Our discussions suggest that the difficulties of establishing a stable and lasting peace are aggravated by the fact that all nations, whether or not they possess nuclear weapons, might produce biological and chemical weapons, international tension would consequently be increased

Potentialities of Biological and Chemical Weapons

Biological weapons—microbes, viruses and their toxic products—can be delivered and dispersed in such a way that fatal or incapacitating diseases might be produced over large areas They can be produced cheaply on a significant scale, even in a country the technological development of which is not highly advanced Such weapons could be used either alone or together with others The attack could be local or massive or could consist of individual acts of sabotage The agent could be selected to cause a great many primary casualties, or to initiate epidemics

Infective agents or toxins used as biological weapons would presumably have the following characteristics (*a*) lethal or incapacitating when applied in small amounts, (*b*) remain potent when stored or dispersed, (*c*) the diseases they produce should not be preventable by simple sanitary precautions, or by customary practices of immunization, (*d*) neither the agents themselves nor the diseases they produce should be easily identifiable, (*e*) the diseases they produce should not be curable by customary drugs or antibiotics Many well-known biological agents possess several of, or all, these attributes The simultaneous use of two or more pathogenic organisms might assist the spread of infection and confuse diagnosis

Highly virulent strains of some pathogenic agents can easily be selected, as can strains of virulent bacteria resistant to the usual antibiotics, drugs and to some disinfectants Recent advances in microbial genetics make it possible to produce variants, some of which may be even more suitable for biological warfare than naturally occurring strains

Quantitative information on the infectivity and toxicity for man of biological agents that might be used as weapons is too meagre for their effects to be compared at all accurately with those of nuclear weapons However, a surprise attack on a city might in time cause numbers of casualties approaching those caused by a small atomic bomb An attack with an infective agent, originally meant to be localized, might lead to an epidemic because of abnormal routes of delivery, the large number of primary casualties, or the disorganization of public health

The meteorological and other conditions required for biological or chemical attacks on man are so exacting that the military effects will be far from certain The necessary conditions for a successful attack might prevail only on some days and at limited times of the day, and would be subject to the errors of meteorological forecasting The discharged material, instead of moving into and staying in the intended area, might recoil on the aggressor Biological weapons would presumably be stabilized to withstand exposure to the atmosphere and so might remain active for long periods and ultimately fall anywhere

Attacks on economically useful animals are subject to many of the same limitations as attacks on man The most likely use of biological warfare on animals would be to disrupt the economy, which could be done by introducing various infections that spread very rapidly and some of which are transmissible to man

There are also agents that could be used to destroy crops, but their effects are unlikely to be important compared with attacks on human beings and animals Chemicals such as plant hormones would produce the quickest and perhaps the most serious results, but to be effective would have to be applied over great areas Some infectious diseases of plants could also be damaging, their introduction, however, could adversely affect the economy of a region for a long time, but most of them spread too slowly to influence the outcome of a war

Chemical weapons ('poison gas' or other poisonous substances) were used in the First World War and several subsequent occasions In recent years, new poisonous substances have been produced which are many times as active as the earlier agents Means for their bulk production have also been improved, as have procedures for their dissemination over areas very much larger than those covered during chemical attacks in the First World War The production of chemical warfare agents could easily be disguised as peace-time chemical industry, or such industry could be quickly converted to produce them

The so-called nerve gases, which are chemically similar to certain insecticides, are extremely potent and cheap, and cannot easily be countered with effective defensive measures Masks and appropriate clothing can partially protect against them, but it is difficult to apply such protection to large populations, and it is unlikely that nerve gas casualties could be treated with antidotes soon enough after an attack to prevent serious consequences New types of hallucinating agents or of poisons that give rise to transient mental disorganization, without recognizable permanent injury, have been advocated as means of 'humanizing' war Although they do not kill directly, their use could have serious consequences, because individuals or groups of people exposed to them behave unpredictably and often irresponsibly The extremely high level of toxicity of new types of poisonous materials, as well as the means available for their delivery, permit their effects to be compared with those of certain types of atomic weapons

Summarizing the previous paragraphs, biological and chemical agents clearly represent considerable additions to modern arsenals Yet, we realize that nuclear weapons, particularly modern hydrogen bombs, have a destructive power several orders of magnitude greater than chemical or biological weapons As means of immediate and certain destruction, these weapons cannot compare with hydrogen bombs The dependence of biological weapons on uncontrollable factors, such as meteorological conditions, and the difficulty of confining the effects to the attacked territory, make them especially unpredictable in scope and effect

World-wide apprehension about biological and chemical weapons can be allayed only by measures tending to assure that they will not be produced or used But, however difficult the international control of atomic weapons may be, the international control of biological and chemical weapons by any system of inspection seems incomparably more difficult

The first reason is that the specific weapons, or combinations of weapons, likely to be used in a particular instance cannot be foreseen

The second is that chemical or biological weapons can be selected and prepared in ordinary chemical or microbiological laboratories The fact that no elaborate or large-scale facilities are needed makes it difficult to identify possible places of preparation for biological or chemical warfare Even elaborate installations would resemble those normally used in the production of vaccines or antibiotics It follows that small and large nations, whether industrially undeveloped or highly industrialized, might secretly prepare to use such weapons, and with each added nation possessing such capabilities, the danger of war would mount

A third reason is that means of dispersal of chemical and biological agents of warfare are diverse, including aeroplanes, submarines and missiles, as well as saboteurs Their delivery, therefore, cannot be prevented because it would require a ban on all forms of transport, civil as well as military

If control by inspection is so extremely difficult, what alternative ways are there to decrease the danger that chemical and biological weapons will be used? It seems clear that international renunciation of the use of such weapons, as in the 1925 Geneva Protocol, cannot allay apprehension unless all nations, small as well as large, ratify such an agreement without reservation This is the first necessary step

Secrecy is clearly essential to preparations for biological and chemical warfare On one hand, it enables any nation planning aggression to depend upon the element of surprise, and upon the opponent's lack of effective counter-measures taken in advance On the other hand, the unknown is, of itself, a potent cause of human anxiety, and is even more so when associated with weapons of any kind Any actual danger there may be will certainly be exaggerated wherever information about any aspect of the situation is denied Secrecy on the part of possible enemies is even more productive of anxiety, suspicion and hostility, and may precipitate hostile reactions Free and frank revelation of all scientific and technical developments is essential to a degree of mutual trust necessary to resolve the acute tensions that now plague the world

The most hopeful approach to international regulation therefore seems to comprise (*a*) a general agreement to prohibit the use of such weapons, and (*b*) the renunciation of official secrecy and security controls over microbiological, toxicological, pharmaceutical and chemical–biological research

In considering how to implement the second of the foregoing proposals, we note the already excellent effects of the Report of the U N Scientific Committee on the Biological Effects of Radiation A comparable scientific committee, or a permanent U N Scientific Commission on biological and chemical modes of warfare, could help to dispel apprehension A subsidiary function of either group might be to investigate impartially the claims by plaintiff nations that others had openly or surreptitiously used methods of biological or chemical warfare against them

The very existence of such a Commission might in time arouse the conscience of the individual scientists of all nations, the only ultimate effective safeguard against violations

In agreement with the Third Pugwash Conference in Vienna, we repeat that, in the end, only the absolute prevention of war will preserve human life and civilization in the face of chemical and biological as well as nuclear weapons No ban of a single type of weapon, no agreement that leaves the general threat of war in existence, can protect mankind sufficiently We therefore must look forward to a day when the preservation of peace will transcend the ambitions of individual nations

Trust between nations cannot be established by proclamation, but only by experience, particularly by experience in co-operative work toward common aims There is already an extensive interchange of scientific information and people in the sciences basic to the problems discussed in this statement We must build on this The Commission proposed to collect and evaluate information bearing on chemical and microbiological warfare should serve not only to allay the fears of mankind that new and ever more horrible weapons of such types will be invented but also to dispel the miasma of secrecy that fosters international suspicion and tension, and in its place to extend the benevolent application of microbiological and chemical knowledge for the benefit of all men

OBITUARY

Dr. B van der Pol

After a brief illness, Dr Balthasar van der Pol, a director of research in radio science, university professor and international Civil servant, died at his home in The Netherlands on October 6, at the age of seventy

Dr van der Pol was born on January 27, 1889, at Utrecht, The Netherlands, where he was educated and obtained his degree in physics at the University of Utrecht in 1916 In that year he went to study under Prof J A Fleming at University College, London He proceeded to Cambridge in the following year, where he worked in the Cavendish Laboratory as a foreign research student under Sir J J Thomson He was very interested in the Heaviside layer theory of the reflexion of radio waves, and carried out experiments designed to show that ionized air in an electric discharge could act as a radio wave reflector He was successful in this work, and on returning to Holland in 1919 he was awarded his doctor of science degree for a thesis on "High Frequency Measurements of Glow Discharges", and became assistant to Prof H A Lorentz at Teyler's Institute, Haarlem

In 1922, Dr van der Pol was appointed physicist in the research laboratory of the N V Philips works at Eindhoven, where he later became director of research in radio science He was appointed knight of the Order of Oranje Nassau in 1927, for establishing the first radio-telephone communication between the Netherlands and the Dutch East Indies Concurrently with his service in the Philips organization, he was professor of theoretical electricity in the Technical University, Delft (1938–49), and he was president of the temporary University founded at Eindhoven to replace other Netherlands universities in occupied territories, for which service he was appointed knight of the Order of the Netherlands Lion in 1946

Van der Pol was interested in a wide range of mathematical and physical subjects, and was the author of a number of papers published in scientific journals, these included two lectures delivered before the Wireless, and later Radio, Section of the Institution of Electrical Engineers in London on "Discontinuous Phenomena in Radio Communication" (*J Inst Elect Eng*, 81, 381, 1937), and "The Fundamental Principles of Frequency Modulation" (*J Inst Elect Eng*, Part III, 93, 153, 1946) He also published a book jointly with Dr H Bremmer on "Operational Calculus based on the Two-sided Laplace Integral" (Camb Univ Press, 1950) He was a member of both the American and London Mathematical Societies, of the Netherlands Royal Society, a founder member of the Netherlands Radio Society, fellow, and vice-president for 1934, of the Institute of Radio Engineers (N Y), and an honorary life-member of the Institute of Radio Engineers

(Australia). He was awarded the Medal of Honour of the Institute of Radio Engineers (N.Y.) in 1935 for contributions to circuit theory, and in 1953 the Danish Academy of Technical Sciences presented him with the Valdemar Poulsen Gold Medal for outstanding contributions in the field of radio research and for international scientific co-operation in matters related to radio communication.

Dr van der Pol became greatly interested in the scientific and technical aspects of international radio affairs and, from 1927, he was a well-known participant in a large number of conferences in all parts of the world. He was vice-president of the International Scientific Radio Union during 1934–50, and was elected an honorary president in 1952.

He was appointed the first director of the International Radio Consultative Committee in 1949, and held this position until his retirement in 1956. As the permanent executive officer of the Committee, he was the technical adviser to the International Telecommunications Union on the planning and development of radio communications during the post-war years. Until a few weeks ago, he was attending the present conference of this Union in Geneva, representing other international scientific bodies on the allocation of frequencies for radio astronomy and space research. In later years his interest in mathematics developed towards the Heaviside calculus, to the extension of which he made notable additions; he was also interested in the theory of numbers. Since his retirement in 1956, he had been an active lecturer in these subjects, particularly in the United States.

Dr van der Pol was very well liked and respected by the vast number of friends with whom he came in contact throughout the world. His qualities as a scientist and his administrative abilities as an international civil servant always received the highest recognition. He never spared himself in his devotion to the pursuit of knowledge and human understanding on a wide international basis. He was happily married and leaves a widow, a son and two daughters.

R. L. Smith-Rose

NEWS and VIEWS

Nobel Prize for Medicine for 1959

Prof. S. Ochoa

The Nobel Prize for Medicine for 1959 has been divided between Prof. S. Ochoa and Prof. A. Kornberg. Dr. S. Ochoa has long been regarded as one of the principal exponents of the highly successful enzymological approach to the study of intermediary metabolism. His recent contributions to the mechanism of the biosynthesis of nucleic acids have been preceded by a succession of outstanding biochemical discoveries principally concerned with the metabolism of carboxylic acids and with associated phosphorylation reactions. One of the most notable of these discoveries was made in 1939 while he was a research worker at Oxford. He found that large quantities of inorganic phosphate are esterified when pyruvic acid is oxidized by dispersions of brain tissue. This 'oxidative' phosphorylation is recognized as part of the fundamental mechanism whereby energy is made available from biological oxidations. With his students and colleagues at New York University, he has since discovered a number of important enzymes which are involved in the tricarboxylic acid cycle and the oxidation of fatty acids.

Dr. Ochoa's work on nucleic acids originated from experiments on phosphorylation reactions in enzyme preparations from *Azotobacter*. In 1955, together with Dr. M. Grunberg-Manago, he reported the discovery of an enzyme which is able to catalyse the removal of the terminal phosphate group from ribonucleoside diphosphates accompanied by the polymerization of the resulting nucleoside monophosphate residues. In this way, a mixture of the four appropriate nucleoside diphosphates can be converted into a polynucleotide which closely resembles naturally occurring ribonucleic acid, although it is not yet understood how the arrangement of the nucleotides in the polymer is controlled. The discovery is notable because of the structural complexity of ribonucleic acid and because of the essential functions of this material in the synthesis of proteins.

Prof. A. Kornberg

Before making their discoveries in the biosynthesis of nucleic acids, Dr. Kornberg and his colleagues were responsible for many important advances in several areas of intermediary metabolism, including the biosynthesis of nucleotides and nucleotide coenzymes. In 1956, Drs. Kornberg, Lehman, Bessman and Simms described experiments indicating that deoxyribonucleic acid could be synthesized by an enzyme system prepared from *Escherichia coli*. Further study with a purified preparation of the enzyme has shown that the nucleic acid is made from the triphosphates of the four kinds of deoxyribonucleosides and requires the presence of some pre-formed deoxyribonucleic acid. The detailed results substantiate the elegant hypothesis proposed by Drs. Watson and Crick in 1953. Thus, it seems that the double strand of the primer deoxyribonucleic acid becomes separated into its complementary single chains which then act as templates for the assembly of new polynucleotides and finally become two molecules having the detailed structure of the original double-stranded one. Within the past year, Dr. Kornberg and his very active group of research workers have reported an outstanding series of experiments on the synthesis of deoxyribonucleic acid in *E. coli* infected with certain bacterial viruses. Their experiments show that the viruses induce the infected bacteria to develop a number of enzymes which, between them, cause rapid multiplication of the deoxyribonucleic acid of the virus while preventing the formation of bacterial deoxyribonucleic acid. The great interest of these exciting developments is that deoxyribonucleic acid is a characteristic component of chromosomes and is considered to act as the principal carrier of genetic information; the sequences of the four kinds of nucleotides in the long polynucleotide chains are thought to determine the structure of the proteins and hence to control the hereditary properties of living cells.

Applied Physics at Durham : Dr. D. A. Wright

IT was decided recently to set up a Department of Applied Physics in the Faculty of Applied Science within the Durham Division of the University of Durham. This is the first 'applied' department in the Durham Division and is intended to give Durham students closer contacts with industry and to contribute to the training of applied scientists. The first professor of applied physics, Dr. D. A. Wright, will take up his appointment on April 1, 1960. Dr. Wright graduated with a first-class honours degree in physics at the University of Birmingham in 1932 and later carried out research at Birmingham for which he was awarded the M.Sc. In 1955 he was awarded the degree of D.Sc. of the same University. Since 1934 Dr. Wright has been a member of the scientific staff of the research laboratories of the General Electric Company, Wembley, and is now head of the Combined Electron Physics and Solid State Physics Laboratory. His research groups have published work of high quality in the fields of thermionics and semi-conductors. Dr. Wright's recent work has been concerned with thermo-electricity, a subject which may well have considerable industrial and commercial applications. Dr. Wright has taken an active interest in the Physical Society and the Institute of Physics. He is treasurer of the Physical Society and represents it on the Parliamentary and Scientific Committee.

New Geophysical Observatory in Belgium

THE magnetic observatories founded in the nineteenth century near large cities are steadily having to be transferred to areas remote from electric transport. This happened many years ago for Kew and Greenwich. Now the Royal Belgian Meteorological Institute has had to transfer its magnetic observatory from Uccle, near Brussels, to Dourbes in south-east Belgium. The new observatory had to be sited at least 15 km. from present or potential electric transport, a requirement more difficult of fulfilment in Belgium than in the British Isles. The opportunity has been taken to build a truly magnificent comprehensive geophysical observatory, equipped for recording the terrestrial magnetic elements, earth currents, atmospheric electricity, radio atmospherics, radioactivity in the air, seismic waves, and ionospheric variations. The observatory is lavishly described with detailed descriptions of buildings and instruments, photographs (many in colours) and architectural plans in a recent publication of the Institute (Institut Royal Meteorologique de Belgique. Publications Serie A, No. 7: Réalisation du Centre de Physique du Globe à Dourbes. Par Prof. E. Lahaye. Pp. 104. Bruxelles: Institut Royale Meteorologique de Belge, 1958). This publication will be studied with great interest, and some envy, by those responsible for geophysical observatories in other countries. The detailed building plans which it contains will be invaluable in designing other new observatories or in re-designing existing ones.

Atmospheric Sciences Advisory Panel

THE U.S. National Science Foundation has announced the names of six scientists who will form the Foundation's Advisory Panel on Atmospheric Sciences. The purpose of the Panel is to provide advice to the Atmospheric Sciences Programme on the development of a programme of basic research and supporting facilities, including such fields of science as physics, engineering, oceanography, meteorology and mathematics. The Panel will consist of: Dr. Thomas F. Malone, director of research, Travelers Insurance Co., Hartford, Connecticut; Dr. Walter H. Munk, professor of geophysics, University of California at La Jolla, La Jolla, California; Dr. Walter Orr Roberts, director of the High Altitude Observatory, University of Colorado, Boulder, Colorado; Dr. Verner E. Suomi, professor of meteorology, University of Wisconsin, Madison, Wisconsin; Dr. Arthur H. Waynick, director of the Ionosphere Research Laboratory, Pennsylvania State University, University Park, Philadelphia; and Dr. E. J. Workman, president, New Mexico Institute of Mining and Technology, Socorro, New Mexico.

U.S. Expenditure on Research and Development for 1957

A PRELIMINARY report on a survey conducted by the Bureau of the Census for the National Science Foundation indicates that funds for research and development in private industry in the United States in 1957 totalled 7,200 million dollars, compared with 6,000 million dollars in 1956 (Reviews of Data on Research Development No. 14, August 1959: Funds for Research and Development Performance in American Industry, 1957. Pp. 6. Washington, D.C.: Government Printing Office). The aircraft and electrical equipment industries accounted for more than half (2,544 million dollars and 1,170 million dollars, respectively), representing increases of 21 per cent and 24 per cent on 1956 figures. Motor vehicles and other transport, and the machinery industries, were next with 708 million dollars and 688 million dollars, followed by industrial chemicals (384 million dollars), petroleum refining and extraction (230 million dollars) and communications (206 million dollars), the percentage increases over 1956 being 6, 22, 14, 23 and 16. Scientific and mechanical measuring instruments increased by 30 per cent, to 126 million dollars. Of the total of 7,200 million dollars, 3,700 million dollars came from Federal funds, which represented 85 per cent of the total in the aircraft industry and 61 per cent in the electrical industry. Expenditure on basic research totalled 241 million dollars, and of this 52 million dollars were expended by the aircraft industry, 38 million dollars by the electrical equipment industry, 30 million dollars by the petroleum refining and extraction industry, and 29 million dollars by the chemical industry. The physical and mathematical sciences claimed 54 per cent of the expenditure on basic research, engineering sciences 36 per cent and the biological sciences about 10 per cent.

The Acute Radiation Syndrome

ACCIDENTS which result in exposure of man to doses of ionizing radiation in the lethal range are sufficiently rare to be extremely important. A report by the United States Atomic Energy Commission (Report ORINS-25: The Acute Radiation Syndrome—a Medical Report on the Y-12 Accident, June 16, 1958. Compiled by Marshall Brucer. Pp. viii+188. Washington, D.C.: Office of Technical Services, Department of Commerce, 1959. 1 dollar), which follows closely to a similar one from France (Jammet, H., *et al.*, "Etude de six cas d'irradiation totale aigue accidentelle", *Rev. Franc. d'et. Clin. et Biol.*, 4, 210; 1959), therefore merits study by physicians, radiobiologists, health physicists, administrators and the daily Press It is an account of the men who were subjected to mixed neutrons and γ-rays from an unanticipated critical assembly of enriched uranium, five to doses of some 200–400 rads, three to some 30–60 rads The clinical features and progress are compared with hæmatological findings and the dosimetric estimations and calculations of the health physicists Twelve sections are contributed either by the various physicians and scientists responsible for the routine handling of the cases or by special research workers A final section is a complete appreciation by Dr Marshall Brucer, chairman of the Medical Division, Oak Ridge Institute of Nuclear Studies Dr Brucer makes the point that initially the physician is on his own The health physicist can at first classify those at risk only into three groups according to dose low (less than 250 rads), high (greater than 1,000 rads) and intermediate The first need no specific medical treatment, the second humanitarian care, but the third present problems requiring judgment The symptoms (especially vomiting and fatigue) can help the physician initially to identify the three classes The lymphocyte-count in peripheral blood is the next guide Later, particular amino-acidurias will be important, and later still the platelet-count of the blood Meanwhile, the health physicist can have reconstructed the incident, assayed the body fluids for induced radioactivity and made a more refined assessment of the doses received "A conservative rule to follow during the first few weeks is that there should be a plain and unmistakable indication for anything that is injected into the body Probably the most important feature in treating psychological upsets is to see to it that the hospital is not turned into a zoo "

Health and Industry

The annual report of the Chief Inspector of Factories on Industrial Health for 1958 is notable for two special chapters, one of which deals with occupational cancer, while the other describes a study of medical supervision in 210 factories (Ministry of Labour and National Service Pp iv+61 Cmnd 811 London H M Stationery Office, 1959 3*s* 6*d* net) The report also particularly invites members of the medical profession generally who could add to available knowledge of health hazards to report to the Medical Branch of the Inspectorate cases of interest coming to their notice in which occupational factors might be involved Such information could assist the discovery of new industrial hazards and lead to a fuller assessment of the extent and distribution of recognized industrial diseases The Industrial Health Advisory Committee, besides considering the report of a survey by the factory inspectorate on cardrooms in the cotton industry, designed to ascertain progress made in meeting exhaust ventilation requirements, appointed a sub-committee to collect and assess information as to the need for more chemical, physical and biological testing in factories with a view of reducing the risks of injury to health Although the Work in Compressed Air Special Regulations, 1958, have not been in force sufficiently long to assess their effect on the incidence of compressed air illness, progress is apparently being made and often a high standard of welfare achieved beyond the minimum standards laid down Attention is directed to the need for a careful watch for any health hazard from dust from the new 'chromizing' process of forming a surface layer of chromium over steel articles, and of aiming at complete suppression of dust or fume in the fabrication of alloys by addition of 2 per cent of beryllium to copper The chapter on occupational cancer gives a concise summary of existing knowledge that medical supervision in factories indicates that medical examination of work-people is usually regarded as the most important function of a works doctor, advice about factory conditions appear to come next, and then emergency and accident treatment and treatment for minor sickness

Study of Corrosion

The fifth report of the Corrosion Committee of the Iron and Steel Institute appeared more than twenty years ago Although no further report was published, the work has been carried on continuously, and the present sixth report which is now available deals with this (Iron and Steel Institute Sixth Report of the Corrosion Committee Compiled by Dr J C Hudson. Pp x+217 Special Report No 66 London Iron and Steel Institute, 1959 63*s*) The Committee of the Iron and Steel Institute ceased to function as such in 1946 when its work was taken over by the British Iron and Steel Research Association, and the work now published was therefore carried out under the auspices of both organizations This report consists of an extensive introduction in which the work of the Committee since 1938 is discussed as a whole This is followed by two sections dealing at length with unreported work on atmospheric corrosion in air, soil and water The final results are given of an extensive series of field tests on a wide variety of structural irons and steels carried out all over the world, and in some cases with an exposure time of up to fifteen years Section 3 of the report deals with the protection of steel against highly corrosive, humid atmospheres at temperatures up to 300° C, while Section 4 is devoted to marine corrosion and includes the results of several service trials of painting procedures and anti-corrosive compositions for ships' hulls There can be no doubt that the work published is of first-rate importance to all concerned with the preservation of structures, land and marine, against rust, and it is doubtful whether the Iron and Steel Institute has ever published a report of more far-reaching significance

Building Research in Britain

The annual report of the Building Research Board of the Department of Scientific and Industrial Research will be of interest to all who plan, design or construct buildings (The Report of the Building Research Board with the Report of the Director of Building Research Pp iv+72+12 plates London H M Stationery Office, 1959 5*s* 6*d* net) The summary of research work in hand, or recently completed, includes topics as diverse as the development of large perforated bricks, design of radiation shields, earth pressures on tunnels, supplementary artificial lighting, reinforced light-weight concrete, and rubber concreting skips The need for durability in buildings causes some investigations to extend over many years, and summaries of results obtained so far are a useful feature of the report The building industry is often accused of being the least efficient branch of engineering, and the slowest to apply the results of research, although the Building Research Station devotes much effort to making its discoveries known In order to improve the methods employed, a survey has been started of what information reaches contracting firms, and what is done with it at various levels. This investigation might well be extended to include architects, engineers and other research organizations. The inquiries and special investigations undertaken during the year reflect trends in the industry. Curtain walling systems were prominent, and interest is increasing in heating, heat and sound insulation, acoustics and lighting. The appendixes include lists of building research publications and of films on loan.

Radio Research

IN the years immediately prior to the International Geophysical Year, routine vertical incidence radio soundings of the ionosphere were carried out at about seventy stations, and during the International Geophysical Year both the number of sounding stations and the scope of the observing programmes were greatly increased. The experimental data, which such soundings provide, take the form of curves of equivalent height of reflexion (h') against frequency (f), so-called 'ionograms'. It has always been recognized that the equivalent height of reflexion of the radio waves is often quite different from the actual height of reflexion and, indeed, in the early years of radio sounding it was shown that, in general, the experimental $h'(f)$ curve could not yield unambiguously the true height/electron density profile. Furthermore, the calculation of true height is itself a matter of some complexity, especially when proper allowance is made for the influence of the magnetic field of the Earth. Hence it is, until recent years, that ionospheric workers have based their studies on parameters such as the critical frequency, the equivalent height and the 'M' factor—quantities which could be immediately read from the ionograms. However, the advent of the electronic digital computer has made possible the large-scale conversion of $h'(f)$ curves into $N(h)$ profiles, and as part of the world-wide International Geophysical Year programme a number of organizations formulated programmes for the determination of $N(h)$ profiles for representative stations and for selected observational periods. The Radio Research Special Report No. 28 prepared by Dr. J. O. Thomas and Mr. M. D. Vickers describes in detail the electronic computer programme and method adopted as part of the British International Geophysical Year ionospheric programme (Department of Scientific and Industrial Research: The Conversion of Ionospheric Virtual Height–Frequency Curves to Electron Density–Height Profiles. Pp. v+48. London: H.M. Stationery Office, 1959. 3*s*. 6*d*. net). A useful manual method for making these calculations is described in an appendix to the report and an excellent classified list of papers on this subject is also included.

Natural History in the Midlands

IN connexion with the centenary celebrations of the Birmingham Natural History and Philosophical Society in 1958, Mr. K. L. Kenrick has written an interesting and very readable account of the records of the Society and the story they tell (Pp. 52. Birmingham Natural History and Philosophical Society, 1959.). The longest of these deals with the sixteen volumes of the *Midland Naturalist*, 1878–93, including brief biographical notes on leading members of the Society, as does the section dealing with the activities of the Society between the two World Wars. After the destruction of the Society's rooms at Avebury House on October 25, 1940, activities were suspended until the end of hostilities, but the Society in 1954–55 was once more installed in the Birmingham and Midland Institute, its original home, where the Society's library, its Wynn entomological collection, the J. W. Moore collection of British butterflies and moths, a purchased entomological collection and the Archer-Overton collection of land, freshwater and marine shells are housed.

Equus przewalskii

THREE short articles by A. G. Bannikov, E. Dagva and D. Tzevegmid (*Priroda*, 5, 50; 1959) deal with the Mongolian wild horse (*Equus przewalskii*) in its native habitat and in captivity. Its present habitation area is roughly delimited by 44° N. to 46° N. and 90° E. to 95° E., a small area situated on the border between Mongolia and Sinkiang. Recently a herd of wild horses has been observed along the Takhin Shara-Nuru range, but in the opinion of observers, both the area and the number of individuals are rapidly being reduced. Drastic legislation is suggested to combat the illicit hunting of these rare animals. The effects of acclimatization of the Mongolian wild horse and the hybrids are discussed in another article by I. S. Sles (*Priroda*, 5, 53; 1959).

Spilogale Revised

VOL. 117, article 5, of the Bulletin of the American Museum of Natural History (pp. 229–392. New York, 1959. 2 dollars) is a taxonomic revision of the spotted skunks of the genus *Spilogale* by R. G. Van Gelder, assistant curator in the Department of Mammals. The spotted skunks are distributed over the greater part of the United States and Central America; they are black animals with a complex pattern of white markings which, although almost infinite in their variations, appear to be modifications of a single basic pattern of stripes. The older taxonomists regarded most of the variations as distinct species so that by 1906 Howell listed fourteen species and six subspecies. As a result of the present author's study of a long series of specimens (nearly two thousand), and particularly of local populations, this list is now mercifully reduced to two species, one *S. putorius* polytypic with fifteen subspecies, the other, *S. pygmaea*, monotypic. The characters and measurements of the different subspecies are discussed in detail and illustrated with excellent figures of colour pattern and skull form. The paper concludes with a discussion of the evolutionary trends of the genus in size, colour pattern and skull characters, and a consideration of the clines that occur in the populations of many areas. There is a full bibliography.

Female-sterile Flowers in *Fuchsia*

THE production of female-sterile flowers by hermaphrodite plants of *Fuchsia procumbens* has been described and discussed by M. Holdsworth (*Trans. Roy. Soc. New Zealand*, 86, 105 (1959)). *Fuchsia procumbens* flowers annually in late summer. The brief flowering season begins and ends with the production of a proportion of imperfect flowers—some fall without opening, others open normally but have defective styles and stigmas. Continuous long-day treatment extends the flowering season and increases the number of flowers produced throughout, but this is supposed not to be directly a day-length effect on flower initiation but on vegetative growth. Neither bud abscission nor female sterility could be shown to be simple day-length effects, but both appear to be induced primarily by low temperatures, in conjunction, perhaps, with long days in the case of abscission, and short days in the case of style abortion.

Reorganization of Root Apices after Irradiation

UNDER this title F. A. L. Clowes has described experiments in which roots were irradiated with X-rays and then fed with adenine-8-^{14}C at various intervals afterwards to observe the effect of the radiation on the sites of deoxyribonucleic acid synthesis and hence on the behaviour of the meristem (*Annals of Botany*, N.S., 23, 205 (1959)). Dividing meristem cells may be so badly damaged that they stop synthesizing deoxyribonucleic acid and dividing; and when this occurs root growth may continue by the formation of a new meristem. The latter often originates in the quiescent centre, the cells of which do not normally synthesize deoxyribonucleic acid or divide. These apparently constitute a reservoir of cells which are less vulnerable because of their quiescence; but are able to restart deoxyribonucleic acid synthesis and division when the normally meristematic cells cease to do so. Because of this re-organization of the apex, Clowes considers that it is not legitimate to argue about the behaviour of normal root meristems from chimeras induced by irradiation.

Palæotemperatures and the Origin of the Deep Sea Fauna

A CRITICAL review of the methods of determination of the temperatures of ancient seas by the measurement of the oxygen isotopes ratio in fossil calcareous organisms is given by Y. A. Birstein (*Priroda*, 5, 21; 1959). It is based partly on the work published in the Soviet Union and it leads to certain new ideas regarding the origin of the deep sea fauna. Thus the author of this review is casting doubt upon the conclusions of C. Emiliani and C. Edwards (*Nature*, **171**, 887; 1953), regarding the sharp changes of sea temperatures during the late Tertiary era, and also about those of A. Fr. Bruun (*Nature*, **177**, 1105; 1956) regarding the extinction of the deep sea fauna. According to the author all the deep oceanic regions must be considered to be regions of a relatively constant temperature, affording a place of refuge to many animal species which have eventually died out in the waters of a lesser depth.

Liquation Differentiation in Magma

A NEW contribution to one of the most controversial problems in petrology—liquation differentiation—was made by V. I. Lebedinsky (*Priroda*, 12, 99; 1958), whose original paper, which he wrote in collaboration with Mo Ke-Min, was published separately (*Bull. Acad. Sci. U.S.S.R., Ser. Géol.*, 12, 64; 1958). In these two papers the authors describe certain peculiar liparite lavas from the Kalgan region of Northern China. The lavas in question contain spherulites and spherulitic aggregates, made of a fibrous mineral. The chemical analysis of the spherulites differs from that of the ground-mass in which they are immersed by a greater amount of silica, soda and potash, and a lower amount of magnesia, lime and water. The author suggests that this rock is a solidified emulsion formed by the separation of the original magma into two immiscible liquid fractions.

A number of petrologists deny the possibility of liquation in natural magmas, although there are a number of experimental results published proving that in certain cases such a phenomenon does occur. Such are, for example, the papers by D. P. Grigoriev (1935), D. P. Grigoriev and E. V. Iskyul (1937), J. W. Greig (1927, 1928), O. F. Tuttle and I. I. Friedman (1948) and E. Roedder (1951). On the other hand, there are also numerous works dealing with spherulitic rocks and spherulites as developed in commercial glasses. Beginning with the classical studies by A. Lagorio (1887), many petrologists were attracted by this subject. A number of them, like F. Y. Loewinson-Lessing (1884, 1905, 1935) and T. L. Tanton (1925), tried to prove that certain spherulitic rocks were indeed products of magmatic liquation. On the other hand, there were many petrologists, such as, for example, D. S. Belyankin (1933, 1949), who has studied both spherulitic rocks and spherulitic commercial glasses, who do not believe in magmatic liquation, and would attribute the spherulitic structure to devitrification in the solid state.

Medicina Experimentalis

ALTHOUGH some think there are already too many scientific journals—and people !—in the world, the birth of a new one is always an interesting event. *Medicina Experimentalis* is the name which has been given to the latest arrival, to be published by S. Karger, and to be devoted to experimental medicine in its widest sense (*Medicina Experimentalis*, 1, No. 1, 1959: International Journal of Experimental Medicine. Pp. ii+68. Six numbers per volume (two volumes annually). Subscription price per volume 56 Swiss francs. Basel and New York: S. Karger, 1959). The foreword deplores the tendency of research workers "to shut themselves up hermetically in their ever narrowing specialist circles" and states that the aim of the sponsors is to provide a completely international journal which will cover the wide—and ever widening—fields of experimental physiology, pathology and therapeutics and help to bridge the gap between their multiplying specialities. Papers will be published in English, French and German and are to be limited to an overall length represented by 10,000 words. Authors will rarely be allowed to exceed this and will be charged for the excess. In return for this restriction on the verbosity of their clients, the editors promise to publish the papers submitted within three months. In these days of specialization and editorial congestion, these aims are laudable but may be rather difficult to achieve, and the small international conferences which have become so popular may be a better way of dealing with the frustrations of slow publication in parts of the world where they can be conducted successfully in a single language. The first number contains eight papers in German and one each in French and English. As the foreword says, the new journal will be what readers and authors make it. We wish it well.

Improved Gunmetals

THE Mond Nickel Co., Ltd., has announced the production of a new alloy for gunmetal: 85/6.5/3/3.5/2, copper: tin: zinc: lead: nickel. It is claimed that it has better mechanical properties at both atmospheric and elevated temperatures than 85/5/5/5 gunmetal and still retains the same adaptability to the production of pressure-tight castings. When properly made, castings in this alloy have a 0.1 per cent proof stress of around 8 tons/sq. in. with a maximum stress of 16–17 tons/sq in in sections up to 3 in thick The use of the new alloy will enable castings to be more effectively designed, as regards the use of thinner sections, and this could result in a saving of weight and, therefore, cost

New Multi-range Voltmeter

'Taylormeter Model 100*A*' is claimed by its manufacturers, Taylor Electrical Instruments, Ltd , to be the first multi-range meter in Great Britain with a sensitivity of 100,000 ohms/V d c The instrument is suitable for voltage measurements in high-resistance circuits, laboratory and research work, and in television and other electronic fields It can be used in place of a valve voltmeter but without the inconvenience of zero drift, valve replacement and alternating-current supply connexions inherent in valve voltmeters The d c current and voltage ranges are 0 2 µamp to 10 amp and 10 mV to 2,500 V (25,000 V by means of an external adaptor) The sensitivity on a c is 5,000 ohms/V and the inaccuracies on the d c , a c and ohm ranges are 2, 3 and 5 per cent, respectively Another new instrument in the Taylor multi-range universal meter series is 'Model 127*A*', which is a pocket-size meter with a sensitivity of 20,000 ohms/V d c and 1,000 ohms/V a c It is compact and inexpensive, and utilizes the new rugged Taylor moving-coil centre-pole meter and is specially ranged to give maximum reading accuracy for radio and television servicing and maintenance of electrical equipment A large scale, which is easy to read, with a 3¼ in arc, is fitted

Medical Electronics

A detailed and well-indexed bibliography on medical electronics, consisting of 2,200 references, has been prepared by the Medical Electronics Center of the Rockefeller Institute and published by the Professional Group on Medical Electronics, Institute of Radio Engineers, 1 East 79 Street, New York 21, New York (Bibliography on Medical Electronics Pp 91 2 50 dollars) The term 'medical electronics' has been taken to comprise applications of any of the branches of electronics, such as acoustics, communications, television techniques, spectrophotometry, or dielectric heating, to any problems of biological or medical research, therapy, public health and related fields The bibliography is intended to serve as source material, and though a selection has been made from all the available material, references useful both to investigators trained primarily in physics or electronics and to those engaged in biology and medicine have been included The entries are arranged in three sections, the main section consisting of references which are numbered consecutively, listed in numerical order, and grouped together in related topics , a subject index with some cross-referencing , and an author index from which anonymous and editorial matter is excluded although it is included in the previous sections

A Fossil Meteorite (?)

What may prove to be a fossil meteorite was discovered at a depth of 32 metres when excavating a mine shaft in the district of Magadan, north-eastern Siberia As described by A I Shulzhenko (*Priroda*, 5, 115 , 1959) it is an iron meteorite weighing about 15 kgm , and of a specific gravity of 7 82, and which on analyses proved to be composed mainly of iron, with 5–6½ per cent nickel and 0 4–0 5 per cent carbon

University News

Birmingham

The following appointments to lectureships have been made Dr M E Davies (in botany) , Dr C R Sladden (in biology in the Department of Zoology) , D J Blundell (in geology) , K B Haley (in engineering production) , Dr N A J Rogers (in chemistry) , P W Dykes (in medical biochemistry and experimental pathology in the Department of Experimental Pathology)

Glasgow

The report of the University of Glasgow Appointments Committee for the year ended December 31, 1958 (Pp 15 Glasgow The University 1959), records a steep rise in the number of men registered, which at 1,051 is almost double the total for 1951 This is attributed to increasing use of the Committee's services by students, a continuing upward trend in the number of older graduates seeking the advice of the appointments officers, and the increasing number who remain at the University after registering in the final year Of the total, 735 are in science and engineering, and of these, 302 registered during 1958 Of 574 male students obtaining first or second degrees in 1958, 155 were in science, 122 in engineering and 74 in other technology Of the total, 333 remained in Scotland In science, particularly chemistry, there was a proportional increase in the number entering postgraduate research In spite of the effect of the new defence policy there was no shortage of opportunity except for the less able candidates Of all honours degree candidates, 122, or 21 3 per cent, entered the teaching profession compared with 19 6 per cent in 1957, and in science the proportion rose from 21 3 to 23 8 per cent There was a further increase in the number of women registered and a slight decrease in the notifications of vacant posts, but the picture is not significantly different from that of 1957, and insufficient opportunity in Scotland for women graduates persists

Announcements

To commemorate the late Sir Francis Simon, who was Dr Lee's professor of experimental philosophy and head of the Clarendon Laboratory, Oxford, the Low Temperature Group of the Physical Society has instituted a Simon Memorial Prize This is an award to the value of £250 which is to be made at about three-yearly intervals for distinguished work in experimental or theoretical physics Dr Heinz London, of the Atomic Energy Research Establishment, Harwell, is the first recipient of this award

The third reactor school course on the Control and Instrumentation of Reactors will take place during February 1–12, 1960, and will be open to British and overseas students It will be held at Durley Hill, Bournemouth, Hampshire Further information can be obtained from the Principal, Reactor School Atomic Energy Research Establishment, Harwell, Didcot, Berkshire All application forms must be returned by December 11

Erratum In the letter entitled "Colour Centres produced by Radiation in Silica Gel", by Harold W Kohn, published in *Nature* of August 22, "50° C " in line 12, paragraph 2, column 1, p 631, should read "500° C "

DEVELOPMENT TRENDS IN AUSTRALIAN SCIENTIFIC RESEARCH

THE tenth annual report of the Commonwealth of Australia Scientific and Industrial Research Organization covers the year ended June 30, 1958 (pp 174 Canberra Government Printer, 1958 14*s*), in which the Organization expended £6,861,278 on normal research activities, £429,328 on capital works and £123,655 on grants to outside bodies Of its total income of £7,414,261, £5,792,894 was from Treasury funds and £1,267,928 from the Wool Research Trust Fund Grants to research associations totalled £41,260 and for Overseas Research Studentships £60,793 Expenditure on investigations into plant problems amounted to £754,835 , into animal health and production problems, £737,848 , into food preservation and transport, £245,125 , into forest products, £316,322 , into entomology, £215,538 , into fisheries, £171,458 , and into industrial chemistry, £624,169 £577,186 was spent on the National Standards Laboratory, £149,098 on building research, £383,672 on radiophysics research, £384,823 on wool textiles research, £175,792 on fuel research, £119,338 on the wild-life survey, and £154,929 on land research and regional survey A list of staff as well as published papers is included in the report

A representative committee appointed to consider the future development of the National Standards Laboratory found that while the Laboratory was functioning at a high level of efficiency, the staff and accommodation were too limited and future plans should include a well-planned programme of research The testing and calibration service for industry also required expansion, and in sequence with a further recommendation, Mr N A Esserman has been appointed as first director of the Laboratory Further new arrangements with the universities were concluded during the year, including the development of a Biological Inorganic Chemistry Unit in co-operation with the Australian National University, establishment of a joint electron microscopy laboratory at the University of Sydney, and of a readership in dairy husbandry, also at Sydney The design study of the proposed giant radiotelescope has been completed and the instrument is to be constructed on a site near Parkes, New South Wales Some extension of the technical liaison services of the International Wool Secretariat and its affiliated organizations was agreed and the Secretariat and the Australian Wool Bureau are co-operating in making known to clothing manufacturers throughout the world the Organization's Si-ro-set process for the permanent pleating and creasing of garments The heavy pellet developed in the Division of Biochemistry and Animal Nutrition for administering cobalt supplements to sheep has been widely adopted by graziers in Australia The work of the Organization's Plant and Soils Laboratory, Brisbane, has already established that the carrying capacity of the area of Queensland south of the Tropic of Capricorn and receiving good rainfall can be greatly increased by replacing natural pastures by sown pastures, and the work is of special interest to the beef cattle industry

The Division of Soils has developed a new section to meet the increasing demands for study in soil microscopy and its Soil Mechanics Section continued to widen its interests, especially in foundation problems in building, in pavement engineering and in the stabilization of soils Morphological and chemical data are being compiled for three representative profiles of each of the great soil groups which have been recognized in Australia It is proposed to base the main research of the Division of Plant Industry on semi-arid native grasslands at Deniliquin, New South Wales, and to use this as a centre for studies of the establishment and maintenance of sown pasture species under dry-land conditions Studies were continued on the effect of clover on the fertility of the soil and the residual effects of phosphorus, sulphur, boron and molybdenum , on the extraction from *Thiobacillus X* (Thioparus) of an enzyme and some cytochrome components which catalyse the oxidation of thiosulphate to tetrathionate , and on the effect of individual growth substances on cell division and size of fruits Experiments continued on the transfer of resistance to blue mould (*Peronospora tabacina*) from Australian species of *Nicotiana* to commercial varieties of *N tabacum* An extremely dry year was utilized to study the capacity of sown pastures to carry sheep and to persist under high rates of stocking and under different systems of utilization Studies of the effects of nitrogen supply and extension of the growing season on four strains of *P tuberosa* were completed, and an improved electron dialysis technique involving a minimum of damage to the plant tissue has been developed for determining the cation-exchange capacity of plant roots Studies continued on the beneficial effects of wilting on the ensilage of ryegrass and on the drying characteristics of pasture plants as affected by air velocity, humidity and temperature

The two irrigation research stations on which the ways in which irrigated land can be made to keep its fertility are being studied, and the techniques which can be used to reclaim waterlogged or salted soil, continued their research programmes without major change, and the Department of Agriculture, New South Wales, is co-operating in the Murrumbidgee areas in studies of control of iron chlorosis and of effects of waterlogging and salting on the nutrition of apricots and peaches The Division of Animal Health and Production has commenced work on the protozoal blood parasites which cause 'tick-fever' in cattle Good progress is being made towards an understanding of the physiological characteristics which determine heat tolerance in cattle, with a view of selecting them within the European breeds or importing them, by crossing with such breeds as the Zebu or Afrikander Diseases of sheep now receiving special attention are foot-rot and foot abscess, mycotic dermatitis and worm parasites Sheep husbandry and wool production are two of the Division's major research undertakings, with the view of understanding the genetic basis of high wool production, and the nutritional and other physiological mechanisms which enable the inherited capacity for high wool production to be manifested, reducing the heavy losses due to poor fertility and neo-natal mortality in lambs, and discovering the best and most economic means of offsetting the effects of drought by appropriate maintenance rations and husbandry The present status of animal husbandry and production investigations by Commonwealth and State organizations is under review to reveal the nature of the major problems on which attention could most usefully be focused At the Division of Biochemistry and General Nutrition's field stations experiments are being conducted on salt tolerance and supplementary feeding and on cobalt and copper deficiencies, including trials of the cobalt pellets developed to protect sheep from cobalt deficiency and phaleris staggers

No major changes are reported in the research programme of the Division of Entomology, and great stress continues to be placed on the ecological approach An officer has been appointed to study the ecology of the cattle tick in North Queensland, and work on cattle dips and pasture spelling is being intensified In systematics some progress has been made on a revision of the Calliphoridae or blowflies, and revisions of the Pyrgotidae and Acroceridae have been completed Preparation for the Commonwealth–State trial in New South Wales of a proposed method of suppressing outbreaks of the Australian plague locust advanced considerably, and in work on insect pests of stored grain the density of insect population is being studied under conditions of controlled oxygen leakage Relations between chemical structure and insecticidal activity have been examined in the volatile ketones and N-substituted amides of long-chain fatty acids

The Wildlife Survey Section intensified its study of rabbit populations and has initiated investigations of the dingo (*Canis familiaris dingo*) and the fox (*Vulpes vulpes*) Besides land surveys of the under-developed regions by the Division of Land Research and Regional Survey to determine their needs and population, the Division of Biochemistry and General Nutrition is investigating problems of plant and animal nutrition on the Coonalpyn Downs, South Australia, the Division of Animal Health and Production is breeding cattle at Belmont, Rockhampton, Queensland, and the Plant and Soil Laboratory is studying the wallum country in eastern Queensland The Division of Fisheries and Oceanography has built an experimental aquarium at Cronulla to study the behaviour patterns of commercial fish and has devised and tested a method for counting and differentiating phytoplankton at sea There was no change in emphasis of the work of the Division The Division of Food Preservation and Transport initiated, jointly with the New South Wales Department of Agriculture, a three-year investigation of levels of fruit spray residues and their removal The cheese curd fusing machine developed by the Dairy Research Section was put through successful trials and could be the first effective attempt to mechanize cheese manufacture completely Work on the biophysical properties of the giant cells of *Chara australis* was resumed, and a study of the properties of sucrose synthesized by enzymes was completed The co-operative research programmes undertaken by the Division of Building Research steadily increased during the year, including an investigation into the use of ordinary household hot-water heaters, fired by brown coal briquettes for space heating as well as water-heating to lower- and medium-priced houses

The Wool Textile Research Laboratory has developed an improved sampling device for wool and devoted greater effort to shrink-proofing, including the use of oxidizing agents Studies continued on the exchange of water between a mass of wool and the air passing through it, and work in the Division of Industrial Chemistry on the structural analysis of amino-acids has been extended to the peptides A major activity of the latter Division has been in the techniques of extractive metallurgy and a full-scale unit is to be installed for final tests on the recovery of uranium from Dyson's ore by the Weiss–Swinton jigged bed process for continuous ion exchange Also in co-operation with industry the Division has completed an investigation of the fluid bed roasting of copper concentrates and the subsequent locating and electromining of copper A process has been developed for obtaining thorium of high purity, and further kinetic studies were made on the decomposition of sulphide minerals in the presence of water and oxygen The investigation of the constituents of tar from Lurgi gasification plant continued, as well as the study of the production and properties of various kinds of defects in crystals and their bearing on chemical and physical properties of solids, while increasing effort was devoted to the design and development of optical and spectroscopic equipment An investigation on the preparation of substituted sebacic acids of possible value as plasticizers and low-temperature lubricants showed that the isomeric dihydroxysteric acid easily prepared from oleic acid, as well as erythro-dihydroxysteric acid can be converted to α-hydroxy-α-octylsebacic acid by alkali fusion and in considerably higher yields The Coal-Research Section is continuing work on the properties, composition and structure of light oils, tars and pitches produced by the carbonization of Australian coals

The Division of Tribophysics continued its fundamental studies in metal physics, surface physics and the chemistry of solids, and in some co-operative work on the refining of lead the surface properties of liquid lead have been measured in various media by a radiographic technique No new major projects were initiated in the Division of Physics, where the accuracy of the Laboratory's realization of the International Temperature Scale at high temperatures has been considerably increased, and proposals have been formulated for its extension to well below the present lower limit of −183° C, based on an investigation of the dependence on temperature of the electrical resistance of platinum Electronic apparatus designed or constructed includes a photoelectric servo system for the control of a physical balance for measuring strong magnetic fields, a nuclear resonance thermometer using the quadrupole resonance of chlorine, and the control to 1 in 10 of currents up to 10 amp in an electromagnet with a galvanometer amplifier and power transistors No major changes are reported in the work of the Division of Electrotechnology, but its high-voltage measuring facilities are to be expanded Special furnaces have been constructed and preliminary experiments made to determine the conditions of crystal growth most likely to yield satisfactory single organic crystals, while further studies have been made on the dielectric properties of polycrystalline materials and liquids Determinations of the frequency factors and energies of activation of methyl ethers and ketones confirmed that in long-chain compounds the logarithm of the frequency varies linearly with the energy of activation

The continuance of the investigations of the Division of Radiophysics into the practicability of increasing rainfall by seeding clouds with silver iodide by a further large-scale field trial is in progress in the Northern Tablelands region of New South Wales. Development continued of a method for obtaining bearings from existing Distance Measuring Equipment Beams and also research into the purification of semiconductor materials and growth of mono crystals, the transport of charges in semiconductors and the development of junction photo devices. An all-sky camera was installed in October 1957 and photographs of the whole night sky have been taken regularly at five-minute intervals since that time, recording any auroræ that may occur, and in conjunction with cameras at other stations, enabling positions and height of auroræ to be deduced. In solar physics the association between a class of radio bursts conventionally known as type II and optical features in the chromosphere has been investigated, while the main observational programme of the 15-metre wave-length "Cross" aerial was directed towards completing a survey of a belt of the sky, 10° wide, around the galactic equator. The crossed-grating interferometer is producing each day a detailed radio picture of the Sun, and observations of solar radio disturbances continued throughout the year with the Dapto radio spectrograph, which records the Sun's spectrum in the range of wave-lengths between about 1.5 and 7.5 m. The Mathematical Instruments Section completed the construction of the transistorized digital differential analyser and the techniques are being applied to the development of a small general-purpose computer.

DELAYED HYPERSENSITIVITY IN IMMUNOLOGY

THE mechanism of the delayed form of hypersensitivity, originally and still exemplified by Koch's tuberculin reaction, has proved much more difficult of analysis than that of the immediate reaction about the main immunological features of which much is now known. In the symposium on "Delayed Hypersensitivity" held by the British Society for Immunology in London on May 8, the allergic phenomena associated with reactions of this type provided the central theme for discussion.

Little progress towards the understanding of the mechanism of the tuberculin reaction can be expected, as pointed out by S. V. Boyden in opening the Symposium, until the nature of the specific change in the tissues responsible for the hypersensitivity is recognized and can be detected and measured *in vitro*. The injection of tuberculoproteins, when in soluble form, leads to the production of specific antibodies in the blood but not to the appearance of delayed hypersensitivity. Even when these proteins are adsorbed on carbon granules or red cell stromata to provide them with a particulate vehicle, their injection almost invariably results in the development of Arthus-type hypersensitivity. It seems that it is only when these antigens enter the tissues as an integral part of the bacillus, and consequently pass through some intracellular experience in phagocytes, that the animal will respond to a subsequent skin test with a typical delayed tuberculin reaction.

In part, the characteristic delay in the development of the tuberculin reaction might be attributable, as J. Pepys has observed, to the period of several hours needed for the full fixation of the provocative agent to the tissue cells. The simultaneous injection of any agent, such as histamine or hyaluronidase which can accelerate the loss of the tuberculin from the site of inoculation, or of adrenalin which can ensure its retention in the area, consequently much affects the intensity of the ensuing reaction. It follows, therefore, that any constituent present in the tuberculin preparation used that might evoke even a relatively inconspicuous immediate reaction could, by so doing, lead to the dispersal of the factor which was the cause of the delayed reaction and so mask any later manifestations of delayed hypersensitivity. On the other hand, the introduction of the tuberculin in a lipid vehicle prolongs the local retention of the tuberculin, thereby enhancing its potency and revealing in man the presence of degrees of hypersensitivity too low to be demonstrable by intracutaneous tests with large doses of tuberculin.

The discovery by Landsteiner and Chase that in guinea pigs specific delayed hypersensitivity can be transferred by an inoculum of leucocytes when one of serum is ineffective has been further analysed for human beings by H. S. Lawrence. He sought, by making extracts from such cells after their lysis, to identify the 'transfer factor' concerned. This he found to be a stable agent capable of resisting exposure to deoxyribonuclease, ribonuclease and trypsin. With Pappenheimer, he found that it may be liberated from the sensitizing leucocytes by incubation alone or by contact with tuberculoproteins; the latter procedure caused the cells themselves to lose their distinctive property of sensitizing a recipient. Delayed hypersensitivity to coccidioidin is similarly transferable with extracts of sensitizing leucocytes and the specific systemic reactivity so conferred may persist for more than a year.

In seeking some biological meaning for delayed hypersensitivity reactions, Lawrence proposed an extension of Burnet and Fenner's 'self-marker' concept to postulate that interaction between host cells and phagocytozed microbes may produce slightly altered versions of the individual's cellular components by forming intimate (self plux x) complexes. The latter, recognized as foreign by the host, may provoke a cellular immune response (transfer factor) directed against the complex. The cellular immune response takes effect against the host's own tissues in the form of a local homograft reaction wherever and whenever his cells are in appropriate combination with the antigen (x) which has induced the alteration. The effector mechanism (transfer factor) is uncovered following transfer to recipients and in the presence of the test antigen (x) it is postulated that it evokes a train of events similar to that called forth by the intact microbe in the cells of the donor.

N. A. Mitchison further followed up the possible resemblances between delayed hypersensitivity and the homograft reaction by pointing out that in both, the immunological responses appeared to be attributable to the participation of cell-bound antibody. A graft of tissue from one animal to another of the same species provokes the production of both humoral and cell-bound antibody, but the former generally does not destroy the graft Transplantation immunity thus possesses an important feature in common with delayed hypersensitivity Further similarities arise from the routes of immunization used —the intravenous injection of cells provokes only a poor response in the rabbit—as well as from the tempo of the full transplantation immunity reaction which develops before the production of humoral antibody reaches its maximum More significantly, the cellular infiltration of homografts resembles the granuloma induced by tubercle bacillary wax The nature of the cell first stimulated by the antigen may determine the type of the response, so that a single antigen may, in different circumstances, elicit either a humoral or a cell-bound antibody Alternatively, tissue cells may be supposed to possess isoantigens of different kinds each responsible for one kind of antibody

The possibility that a single molecular species of antigen can provoke simultaneously both delayed and immediate sensitivity to different determinant groups on it was discussed by P G H Gell and B Benacerraf In a study of various types of immunological reaction to proteins conjugated with such active haptenes as picryl chloride, they have demonstrated a dissociation between immediate and delayed skin reactivity to the same antigen The absence of recognizable antibodies to the protein carriers used in these conjugates, at a time when their intradermal injection proved capable of exciting a delayed skin reaction, confirms the view that reactions of this type do not depend on conventional antibodies in the circulation at this time, antibodies were present specific to the haptenic group Under other conditions, delayed sensitivity to the haptenic group was also demonstrable They questioned the view that the state of delayed hypersensitivity can be regarded as an early, perhaps immature, stage of immunity Rather, they felt that it should be considered as a distinctive response to certain qualitatively different, possibly less dominant, groups on the antigenic molecule

With the recognition of the close participation of leucocytes in the transference of specific delayed hypersensitivity, J L Gowans's account of the life-history of lymphocytes acquires particular relevance Experiments on rats have shown that the output of these cells from the thoracic duct is sufficient to replace all the lymphocytes in the blood many times daily, the production of new small lymphocytes is much lower and their survival time much longer than was formerly supposed These cells, moreover, appear to circulate freely through the tissue spaces and in this extravascular transit they may be the effector cells in immunological reactions of the delayed type

The features of the immediate and delayed 'tuberculin-type' reactions to trichophytin in guinea pigs that can be evoked either after an infection or an inoculation with the killed mycelium were described by C N Cruickshank, M D Trotter and M R Wood They found that these responses were associated with a transferable passive cutaneous anaphylaxis, but that they could occur in the absence of any detectable precipitating antibodies Chemical fractionation of the mycelium showed that the antigenic material was mainly a polysaccharide containing equal proportions of glucose and mannose Finally, R M Gordon and M Lavoipierre, in discussing immediate and delayed reactions to insect bites, pointed out that in certain instances the late reactions ordinarily attributed to the saliva of the vector may be confused with that caused by some parasite introduced into the tissues at the time

THE ELECTRIC ARC IN WELDING

FOLLOWING the practice of the previous two years, a third "Joining of Metals" Conference was held at the University of Birmingham on June 25 under the chairmanship of Prof E C Rollason, head of the Department of Industrial Metallurgy The subject on this occasion was "The Electric Arc in Welding", five papers were presented, and the conference was attended by about one hundred representatives of industry, the research associations and the universities Prof Rollason explained that the purpose of these conferences was to further the development and teaching of the basic processes underlying the practice of metal joining, and pointed out that, in arc welding in particular, much less effort had been directed towards fundamentals than to the empirical development of modern arc welding processes He then suggested that there were three ways in which the arc interacted with the metal which were of significance in welding First, there was heat transfer from the arc which was responsible for the formation of the weld pool, secondly, the chemico-metallurgical reactions taking place between the high-temperature gases in the arc atmosphere and the weld metal, and thirdly, the transfer of metal droplets across the arc which can take place against gravity and for which no satisfactory mechanism had yet been advanced

Mr D R Milner, of the Department of Industrial Metallurgy, then surveyed the present state of knowledge of those aspects of arc physics which were pertinent to these problems Throughout the main body of the arc electrical energy is utilized to heat the gas to such a temperature that it becomes thermally ionized and is thus able to provide the electrons and ions necessary to carry the required current At the anode the electron stream, and at the cathode the positive ion stream, provide the source of energy for melting the metal For low-current arcs the anode processes are reasonably well established, but less is known of conditions at the cathode However, for high-current welding systems little information is available in either case Heat and mass transfer from the arc column to the electrodes, which determines the reactions occurring between the arc atmosphere and the weld metal and controls the rate at which they take place, is dependent upon the energy dissipated, the gas properties and the mode of heat transfer Of particular interest in this respect are plasma-jets, which Maecker has demonstrated exist wherever there is a constriction in the arc, such as a cathode spot, giving rise to gas velocities of the order of 10^4 to 10^5 cm per sec

Dr G R Salter, of the Department of Industrial Metallurgy, contributed a paper which described the results of an investigation of the absorption of oxygen by titanium melted by an electric arc in an atmosphere of argon containing controlled quantities of oxygen The effect of time, oxygen partial pressure, arc length, current, electrode composition and gas flow conditions had been determined The interpretation of the results led to the conclusion that in this system the rate-controlling process was the diffusion of oxygen across a 'stagnant' boundary-layer of gas of the order of 10^{-3} cm thickness, adjacent to the molten metal, which took place over a high temperature active area where the oxygen was dissociated The magnitude of the active area was determined by the current and arc length, and the thickness of the boundary layer by the velocity of the cathode plasma-jet which impinged on the anode

Mr J B Wilkinson, also of the Department of Industrial Metallurgy, gave an account of work on heat transfer in which energy balances had been determined for arcs operating between a tungsten cathode and a water-cooled copper anode in atmospheres of argon, nitrogen, helium and hydrogen The existence of plasma-jets in these arcs had been demonstrated, their velocities estimated and attempts made to separate the heat transfer from the plasma-jet from that due to electron heating of the anode The interpretation of the measurements of the heat transferred from the plasma-jet was along similar lines to that proposed by Salter for mass transfer, that is to say, with convection transferring the heat to a boundary-layer adjacent to the metal surface Some success had been achieved by the application of a conventional non-dimensional treatment of convective heat transfer with the plasma-jet replaced by an equivalent source of hot gas emerging from a tube

In addition to their role in heat and mass transfer, plasma-jets are also responsible for the transfer of metal droplets from the molten wire electrode to the weld plate This was shown by Mr J C Needham, who described work carried out at the Electrical Research Association in which a study had been made of the detachment and flight of aluminium droplets by high-speed colour photography (8,000 frames per sec) The existence and effect of the plasma-jet could be inferred from a stream of metal vapour emanating from the droplets flowing in the direction of the jet and from the fact that the velocity of the drops continued to increase, with accelerations of $10g$ to $100g$, after they had been detached from the electrode wire, attaining terminal velocities in excess of 500 cm /sec Experimental determinations of the droplet velocity as a function of current, derived from the photographs taken by Needham, and from trajectory determinations by Mr C J Cooksey of the University of Birmingham, compared well with theoretical calculations based on a model in which the drop became detached when the force exerted on it by the plasma-jet exceeded the restraining force of surface tension, and was then freely accelerated across the arc by the impinging gas stream

An interesting characteristic of the electric arc is that if it is intensively cooled, for example, by operating it through a narrow cooled orifice, then the core temperature is increased This is because the conducting area contracts, so that which remains must have a higher degree of ionization and hence a higher temperature in order to maintain the required current Spectroscopists and arc physicists have utilized this property of the arc to heat gas to temperatures up to 50,000° C for the measurement of collision cross-sections and the transition probabilities of ionized and excited atoms and for fundamental magnetohydrodynamic studies. Mr A R Moss, of the Ministry of Supply, elaborated on the behaviour of the constricted arc and showed how it could be harnessed to technological advantage He described the various types of plasma-jet projectors and constricted arc torches developed in the Armament Research and Development Establishment, with emphasis on the design and characteristics of devices operating with a power consumption up to 100 kV amp , although much more powerful equipments were mentioned Their many potential technological applications include the melting, cutting and spraying of metallic and non-metallic materials in non-contaminating atmospheres, chemical synthesis and the production of high-temperature gas streams at hypersonic velocities

D R MILNER

INTERNATIONAL CONGRESS ON ACOUSTICS

THE third International Congress on Acoustics was held in Stuttgart during September 1–8 under the presidency of Prof Erwin Meyer

The first of the series was held in Delft in 1953 and the second in Cambridge, Massachusetts, in 1956 Already the number of participants has risen from the original 600 to more than 1,000, and in the recent congress necessitated the individual papers being read in eight concurrent sessions The mornings were devoted to review lectures, which all could attend These, and the papers presented, covered architectural acoustics, ultrasonic techniques and their applications to the study of molecular physics, acoustical properties of materials employed in industry, noise and its abatement (in particular aircraft noise), physiological and psychological acoustics

If one tries to assess the progress made since the last congress and which is likely to continue in the future, one would perhaps select the last two of these as of most interest The two reviews given on the subject of the noise of jets and the quantity of smaller papers which followed illustrated the strides which have been made since the last congress, where the subject of aeronautics interested but a few speakers The increasing noise-level to which we are subjected has stimulated more research into the functioning of the ear and the human processes of sound perception, which also brought out a stimulating array of papers

In building acoustics and molecular acoustics one has the feeling that the peak of development has passed In the former subject it seems now to be a question of fine adjustments to existing knowledge, while in the latter new developments may only be expected by going to extreme temperatures and pressures with adaptations of existing techniques. To illustrate the importance of noise in daily life and methods of measuring it, the regional authorities of Baden-Wurtemburg opened to the public an exhibit in a Stuttgart Museum entitled "Weniger Larm".

It was announced that the next international congress would be held in Copenhagen in 1962, and if the number of participants should continue to increase at the present rate this will involve the local organization in much hard thinking about how they are to lodge them and deal with the reading of the many papers expected.

This situation is not peculiar to acoustics, but there is a possibility of splitting the auditory into roughly equal numbers of those concerned with physical and physiological acoustics and those interested mainly in architectural, musical and industrial applications. Perhaps two congresses *en suite* with a week-end of social activities and excursions sandwiched between them might overcome some of the difficulties of organization.

The proceedings of the congress are to be published in book form by Elsevier Press. E. G. RICHARDSON

PHOTOGRAPHY IN THE INTERNATIONAL GEOPHYSICAL YEAR

A SYMPOSIUM on photography in the International Geophysical Year was held in Edinburgh on June 6, under the auspices of the Scientific and Technical Group of the Royal Photographic Society of Great Britain.

Following his address of welcome on behalf of the University of Edinburgh, Sir Edward Appleton stated that he believed the effect of the International Geophysical Year on association between geophysicists would be a permanent one, and recalled the descent of the recent great collaboration from earlier International Polar Years. He then described some of the ionospheric work carried out during the International Geophysical Year and directed attention to the valuable part played by photography in making possible permanent records. In conclusion, he spoke of the most striking discovery of the Van Allen radiation belt. Miss Harker, president of the Royal Photographic Society, replied and went on to discuss the wide compass of photography, illustrated by the nature of the subject of the symposium.

The study of aurorae by all-sky cameras was described by Dr. G. M. Thomas, of the Balfour Stewart Auroral Laboratory. He pointed out that remoteness and erratic occurrence make auroral data scanty, and that any casual collection of data is bad statistically. However, full-time observation is a costly matter, but sky cameras could provide the necessary supplement to visual observation. A system was described consisting of a motion picture camera viewing a large convex mirror, the mirror being heated to keep off frost and snow, and a calendar and watch placed in the field of view. Timing of the camera's function was provided by a synchronous motor. A film illustrating the systematic motion of the aurorae was shown. It is of great importance to correlate the sudden alterations which occur with changes in the magnetic field at the ground.

The next contribution reviewed some of the contributions of photographic techniques to rocket and satellite work, and described particularly the ballistic cameras developed at University College, London, for the 'grenade' experiment. This is a method of finding upper-air winds and temperatures by measuring the time of travel of sound from grenades fired from an ascending rocket. The special function of photography here is to locate the grenade bursts with great precision. When the experiment is carried out in daylight, special techniques are necessary to obtain rapid triggering of the shutters by light from the grenades. Experiments under preparation for X-ray observation of the Sun and ultra-violet astronomy of the stars were also described. The latter work is being conducted in collaboration with Dr. H. E. Butler, of the Royal Observatory, Edinburgh, who then described his use of a technique, due originally to Dr. Baker, of the same Observatory, to bring up the detail of very faint interstellar absorption lines. Basically, the problem is to bring out the signal from the 'background noise' grain in the plates, and it is accomplished by careful photometering and summing of the results from many plates, together with subtraction from a standard spectrum to remove the emission structure. The results were extremely impressive, as indeed was the amount of work required to obtain them; a million separate readings from twenty-seven different exposures were obtained.

Dr. C. J. Waddington, of the University of Bristol, described his subject as the study of the 'footprints' of cosmic ray particles. Due to the vastness of his subject, he limited his discussion to an extended series of high-altitude balloon flights with nuclear emulsions made with the avowed intention of monitoring the long-term variation of the primary cosmic radiation. Seventy-three balloon flights were made by a group led by Prof. E. P. Ney (Minnesota). A typical payload consisted of a dozen 4 in. × 4 in. 600μ Ilford G 5 emulsion plates, together with a single counter and an ion chamber. Although protons are more abundant, α-particles were chosen for the study for a variety of reasons, among which were the complications of an albedo of protons from disintegrations and the greater ease of finding and counting α-particle tracks in nuclear emulsions. The results of these observations are still being analysed, but already it is clear that differences in the variation of α-particle and proton flux after a solar flare should ultimately throw light on the properties of the space between us and the Sun.

A paper by Dr. W. I. Arvegwitch, of the U.S.S.R. Academy of Sciences Institute of Geography, was read for him in his absence. His paper discussed photo-topographic methods used by his Institute for the study of glaciers. For more than a decade glaciation has been studied by aerial photography although stereo-photogrammetric surveys from the ground are still considered to be the most reliable means of recording the state and behaviour of glaciers Recently, however, aerial photography, with its advantage of the avoidance of 'dead areas' due to obstacles, has been applied to the study of glacier dynamics Unfortunately, the paper gave no information on the experimental equipment, either aerial cameras or the new Soviet stereograph "*SD*-1", which was claimed to be notable for its precision, having a relative mean-square error of vertical control in the neighbourhood of 1/3,000 It was a conclusion of the paper that aerial photography could greatly speed up a survey, especially with the use of helicopters, but that no single method in phototopography is appropriate in every situation

The meeting ended with projection of the Russian research film, "North Pole", showing Soviet scientific research in the Arctic and describing the results of oceanographic and meteorological work Of special interest were sequences showing the circulatory movements of water and ice-flows about the Pole

R L F Boyd

GLASSHOUSE CROPS RESEARCH INSTITUTE

OPEN DAY

THE Glasshouse Crops Research Institute, Littlehampton, Sussex, held its annual open day on June 10 when nearly two hundred visitors attended The laboratories were open for inspection during the morning, and after lunch, at which the director, Mr F W Toovey, reported on the Institute's progress during the past year, a series of demonstrations were arranged in the experimental glasshouses and mushroom sheds

In tomato variety trials by the Plant Breeding Section (Mr L A Darby) special interest was shown in hybrids with the 'Baby Lea' variety, some of which are in the F_5 generation and beginning to breed reasonably true This variety has a compact habit of growth (short internodes), and an attempt is being made to incorporate this habit into known good combining varieties with the aim of producing an F_1 hybrid of good early and total yield, bearing high-quality fruit, and which will not suffer from the excessive vigour of hybrids at present grown commercially A cucumber-breeding trial, which was also demonstrated, tests the value of F_1 hybrids for commercial use with special reference to early and total yields, and to fruit quality

The Plant Physiology Department (Dr E R Leonard) showed the concluding stages of a time-of-planting experiment carried out as part of its growth analysis studies on the tomato Previous work has suggested the influence of day-length on the growth of all the major organs of the plant, including the roots, and in order to investigate this more fully sowings at one of the dates included in the main time-of-planting experiment have also been carried out at three other centres in the British Isles, ranging from Guernsey in the Channel Islands to Auchincruive in Scotland, and in Malta and Finland A prototype temperature-controlled glass cabinet, erected in a glasshouse, for studying the growth of tomato plants under controlled day-length throughout a cropping season was also on display Another exhibit was equipment for the production of artificial temperature gradients across a tomato fruit in connexion with the Department's investigation of fruit ripening disorders, including those loosely referred to as 'blotchy ripening'

The Chemistry Department's programme, under Dr G W Winsor, includes a comprehensive study of the nutrition of the tomato, and a wide range of glasshouse experiments was on view These comprise a basic factorial trial, testing nitrogen, phosphorus, potassium, calcium and magnesium, two experiments on liquid feeding, and an investigation of the effect of magnesium deficiency on yield and its control by applying magnesium sulphate to the soil or to the foliage Determinations of nutrient uptake are a special feature of these experiments Laboratory studies of tomato fruit composition were also demonstrated, these have particular reference to fruit-ripening disorders and may shed light on factors determining flavour Changes in the enzyme activity associated with ripening are also being investigated. The Department also works on other glasshouse crops, and of topical interest were the studies being made of the effects of manganese toxicity on tomatoes, lettuce and carnations A factorial nutritional trial on carnations, testing three levels of nitrogen and potassium in the presence or absence of added phosphorus, magnesium or calcium, was also on view With the cultivated mushroom certain cultural problems are studied, particular attention being paid to various factors of the casing layer in relation to fruiting, evidence has accumulated that total moisture stress has an important influence on fruiting An investigation of the effect of factors of the atmospheric environment on mushroom growth is also about to be taken up, and a prototype controlled-environment chamber for this was on view

The Plant Pathology Division (under Dr L Broadbent) demonstrated the work of its three Departments, Entomology (Dr N W Hussey), Mycology (Mr P H Williams) and Virology (Mr M Hollings) At present the Entomology Department is devoting a great deal of attention to cecids affecting the cultivated mushroom, observations on their life-history were illustrated, and results were presented on the very rapid rate of increase of the larvæ in compost The results of experiments on the control of cecids by the application of γ-BHC to compost or casing were also displayed The Mycology Department showed aspects of its work on the *Didymella* stem rot of the tomato, on cucumber mildew, on carnation wilts and on mushroom fruiting disorders In connexion with the investigation of carnation wilt diseases, a glasshouse experiment on the survival of the pathogens in soil and plant roots was in progress, this involves the growing of carnations, chrysanthemums and tomatoes in rotation in concrete-lined beds to see whether the wilt organisms can be carried over on hosts other than the carnation, even though producing no visible symptoms on those hosts Mushroom fruiting disorders, associated with greatly reduced cropping, have caused much concern to the industry during the past few years, but their investigation has proved very perplexing because of the variety of symptoms produced At the Institute the possible transmissibility of the disorders has been particularly studied, and in recent experiments, which were demonstrated, evidence of artificial transmission and natural spread following the inoculation of beds has been obtained Of special interest in the Virology Department's programme, which is about to be greatly expanded, was the success achieved in rooting meristem cultures of carnations and transferring them to conventional growing media , this work has been undertaken as a prelude to the investigation of heat therapy for carnation virus diseases

The Crop Protection Department (Mr W H Read) had a striking demonstration of the effect of captan in protecting tomato plants from *Didymella* stem rot A glasshouse trial showing the value of the chemical soil sterilizing agents, metham and chloropicrin, in comparison with steaming, was also on view

Among the current activities of the Statistics Section (Mr D Cooke) attention was directed to a survey that is to be carried out, in collaboration with Rothamsted Experimental Station and the Ministry of Agriculture, on the tomato varieties in commercial cultivation in relation to earliness and district This should provide information of particular interest in connexion with the breeding programme and experimental work generally F W Toovey

STUDIES IN RECREATION

UNDER the title "After Work Leisure and Learning in Two Towns", the National Institute of Adult Education has published, for the Manchester and District Advisory Council for Further Education, studies in Bolton and Rochdale by Mr R Ruddock and Dr A Wilson (pp 63 London National Institute of Adult Education, 1959 3*s* 6*d*) Prof R D Waller contributes an introduction explaining the purpose and basis of the two surveys, which give special attention to the twenty to thirty age group, and suggesting a few generalizations Dr Wilson's survey of Rochdale started a few months later than Mr Ruddock's survey of Bolton, and he stresses the quality and quantity of educational and cultural activity in this town of some 86,770 inhabitants While this is probably not less than that of any other industrial town of comparable size in Great Britain probably as many as 40 per cent of young adults have no connexion with any organization outside their job and home The Rochdale Literary and Scientific Society, founded in 1878, has always had the backing of influential scientists, doctors, teachers and others and often exercised considerable influence in educational and cultural matters , its membership has fluctuated between 233 and 350 during the first half of this century, but has since reached 650 Nevertheless, apart from societies promoting religious, musical, dramatic or highly specialized leisure pursuits, the voluntary societies have little success in attracting people in the 18–35 age group, and during the past five years the membership of voluntary societies has fallen by 12–13 per cent

The survey suggests that some of the young adults would welcome the opportunity to live a fuller social life and that others might adopt a similar attitude if parents, school-teachers and employers broadened their horizons and developed their latent interests in society and the problems which face its responsible citizens Dr Wilson suggests that the links between technical students and liberal or non-vocational studies could be developed, for example, by residential courses organized by the Extra-Mural Department of the University of Manchester Nor is full use yet made of the facilities for further education under the part-time day release scheme with a school population of 12,287 in sixty schools, day release from 2,289 technical college students is only 943, 76 from 243 School of Art students, and 19 from 1,883 Further Education Centre students

For Bolton, with approximately double the population (163,800), the statistical picture is similar The population per acre, rates per head and birthrate are very similar there are 25,374 students in 102 schools and the total expenditure on education is roughly double (£2,278,812 compared with £1,115,567) Of the 6,700 technical college students, 2,800 are day release, but there is no day release among 748 School of Art students and 2,700 Further Education Centre students Like Rochdale, Bolton is becoming less dependent on the textile industry, and employment in the textile industries has dropped to less than 25 per cent of the working population, compared with 47 per cent in Rochdale Mr Ruddock estimates that the voluntary societies contribute only perhaps one-twentieth to the cultural activity of Bolton and that the whole cultural life of Bolton is sustained by some 6,000 of its citizens Among the suggestions he makes, all concerned with the upper 30 per cent of the population, in the educational sense, is extended publicity to ensure that more young adults know of the Workers' Educational Association and other serious organizations in the cultural field Many premises require improving and equipment The Central Library is admirably situated for sponsoring experimental provision, and although there is much good teaching of the plastic arts in Bolton, local amateurs could benefit by experience of a more exciting and vital practice which might be offered from outside Besides the provision of special courses for those conducting classes and meetings, Mr Ruddock suggests that the many graduate teachers, lawyers, doctors, ministers, scientists and administrators in Bolton might be encouraged to associate more freely and that executive members of local businesses would gain much from organized group contacts with specialists in science, administration, education and social science, many of whom could be reached through the University Extra-Mural Department or Bolton Technical College

Prof Waller points out that neither survey says much about the large undifferentiated mass—what its members' spare-time activities are, what could be done to interest them and involve them in socially healthy and worth-while pursuits Both surveys support explicitly and implicitly Dr I Trenaman's conclusion, that all cultural and educational activities touch only about half of the population, and that half includes all those who have received higher education. It is the late school leavers who are the most likely to carry on cultural interests into mature life, and there seems good reason to believe that longer schooling, the sensible organization of continuation work and youth activities and the liberal treatment of vocational training would all considerably affect cultural and intellectual interests in later life. Prof. Waller also notes Dr. Wilson's observation that those of the 20–30 age group who are most deeply addicted to television seem to have taken no course since leaving school, have no connexion with church or voluntary society and no interest in any other local society and organization. Possibly only television could induce any desire to participate in communal activities among this group. While the position of established societies and organizations varies—the thriving state of the Bolton branch of the Workers' Educational Association contrasts with a decline of 12–13 per cent of the membership of the Rochdale branch during the past five years—all seem likely to gain from an improved educational system and a better developed service of youth. All would be helped by better and co-operative publicity, perhaps with the assistance of local authorities, and all would be greatly strengthened by public provision of central premises, available to them all without crippling rental charges.

MARITAL FERTILITY IN ENGLAND AND WALES

THE census of 1951 was the first general census since 1911 to include questions relating to the fertility of married women of England and Wales. The answers to these questions have been analysed in the fertility report which has recently been published (Census 1951. England and Wales. Fertility Report. Pp. cxi+251. London: H.M. Stationery Office, 1959. £4 10*s*. net).

The analysis of fertility movements has become of increasing interest to demographers and other social scientists for a number of reasons. In the first place, fluctuations in marital fertility and long-term changes in the fertility-rate have most important effects on the size and structure of the population, particularly in low-mortality areas like Great Britain. Secondly, differences in the fertility of various sub-groups of the population are of considerable sociological interest by themselves, and changes in differential fertility may throw important light on other aspects of social change. It is thus likely that questions on marital fertility will figure in future British censuses as a matter of routine.

The growth of interest in fertility has also led to considerable developments in the method of analysis, in particular, the use of cohort analysis in which the fertility experience of a group of women who were either born or married in the same calendar year is traced throughout their reproductive lives. This method of analysis was used in the statistical reports of the Royal Commission on population, and is now also applied in the Fertility Report in discussing the problem of population replacement.

The fertility questions asked in the 1951 census were limited to married women under the age of fifty at the time of the census. These were asked to state the date of their marriage (and their first marriage, if married more than once), the number of live-born children, and whether they had given birth to a live-born child in the twelve months preceding the census. In addition, the census schedule contained the woman's age, and, if her husband was enumerated on the same schedule, particulars relating to his occupation. In order to simplify the analysis, a sample of 20 per cent of the 7·4 million married women was selected for analysis; an 80 per cent sample of women aged 45–49 was taken to obtain more detailed data on completed fertility. A complete analysis was made of all women who had been married more than once, but such women constituted only 4·1 per cent of all married women.

The fertility report aims to answer three questions. First, what is the current level of marital fertility in England and Wales? Secondly, what differences in fertility between various groups may be detected from the data? Lastly, what are the implications of present trends on population replacement?

It will be convenient to deal with the last topic first. It is interesting to note official recognition of the fact that the question as put is incapable of being given a definite answer. On p. xci of the report a number of different hypothetical replacement-rates, calculated on different assumptions, are put forward, varying between 0·965 and 1·084. The official comment is that "current habits imply *in the long run* approximately full replacement of one generation by the next and possibly very little more" (p. xcii). This is a far cry from the position in the 1930's when warnings about incipient rapid population decline were common. To be fair, however, it should be pointed out that women born in the early years of the century did not have sufficient children to replace themselves (women born between 1903–8 had a generation replacement-rate of only 0·672, those born between 1913–18 0·795). It is clear, however, that in the immediate future, violent changes in total numbers are unlikely.

There are slight indications that the recovery in average family size after the end of the Second World War was slowing down in the middle 'fifties, but it will be necessary to wait for the 1961 census data before we can be certain of this.

It is not the function of an official census report to speculate upon the causes of the reversal in fertility trends, but the chapter on differential fertility gives information about differentials between occupational groups (both the traditional five-fold classification and the twelve socio-economic groups), between different geographical areas, and also an analysis of fertility differences by differences in the ages of husband and wife. The indices studied are mean family size, proportion infertile and current fertility-rate. These figures confirm the impression that clerical workers, shopkeepers and the lower professional, administrative and managerial groups are now the least fertile section of the population, their fertility being about 20 per cent below that of the population as a whole. On the other hand, semi-skilled and unskilled manual workers continue to show an excess of about the same amount.

The report, of course, contains much additional information, some of it incidental to the principal topic For the calculation of replacement-rates, a female nuptiality table showing the proportion of the female population at different ages by marital status had to be computed, assuming current rates of death, marriage and dissolution of marriage, and interesting facts emerge about the marriage habits of different groups of the population

One hopes that the fertility questions will be repeated in 1961, and that the questions will be asked of all married women this time It is only through periodic inquiries such as this that the fertility of the population as a whole can be adequately studied, and the importance of the subject warrants inquiries of this kind to be made at intervals more frequent than once in forty years

E GREBENIK

JOHN INNES HORTICULTURAL INSTITUTION

ANNUAL REPORT, 1958

THE accommodation and facilities at the John Innes Horticultural Institution, the annual report of which was recently published (Forty-ninth Annual Report, 1958 Pp 44 Bayfordbury, Hertford John Innes Horticultural Institution, 1959 3*s*), continue to expand In the Department of Plant Breeding, much work has been carried out in an effort to improve the apple, with special attention to breeding for apple scab and apple mildew Secondary emphasis has been placed on hybridization to fill varietal gaps Pear–apple hybrids have been found to be only possible using the pear as female parent, and there appears to be no fundamental genetic barrier to crossing the two genera, however, hormone treatment is necessary for success Very few of the hybrids have survived the seedling stage, due to rapid breakdown of root tissue This weakness is only partly overcome by grafting and only about 2 per cent of those produced up to 1956 have survived It has been claimed that parental performance can be improved by selection combined with inbreeding and that undesirable characters, such as disease susceptibility, can be removed without impairing the general breeding behaviour of the original genotypes Whether or not worth-while results can be obtained in this manner is controversial, but a programme of inbreeding strawberries has been designed to answer some of these questions The results so far suggest that selfing causes a considerable loss of vigour In practice, changes affecting only one character are seldom brought about by selection after hybridization Such changes are more likely to be achieved if genetic variability can be produced without crossing Experiments on increasing genetic variability of inbred lines of tomato by irradiation using phosphorus-32 indicate that it may be possible to increase quantitative variation in tomato by this means

Self-compatibility in the family Solanaceae and in the genus *Linaria* is being investigated in the Department of Genetics as well as the genetics of *Coprinus lagopus* The Department of Potato Genetics has continued work on various aspects of species relationships Until recently, breeding for resistance to late blight has been based on genes for resistance derived from *S demissum* At first, varieties possessing a single gene for resistance were satisfactory, but eventually succumbed to new races of *Phytophthora infestans* Resistance based on field resistance presumably controlled by a number of genes is thought to be more promising Selection of field-resistant varieties is slow and there is probably scope for varieties incorporating two or three different genes for resistance The genetic variability of the fungus is also being studied as well as resistance of potato varieties to virus *X* and virus *Y* The Department of Plant-Cell Biology has continued studies on leaf growth Observations have continued on the relative contributions of cell division and cell expansion to the second pair of leaves and the tenth leaf of *Helianthus annuus* The tenth leaf reached an area about three times greater than a leaf at the second node, on the other hand, the average volume of the cells of the tenth leaf was only about one-half that of the second leaf The greater size of the tenth leaf is therefore due to longer duration of division rather than a greater final cell size Division continued until the leaf was more than three-quarters fully grown The results refute the older idea that during early development of the leaf, growth is due mainly to formation of new cells and that after division has ceased subsequent growth is due to cell enlargement It is concluded that division and expansion do not determine leaf growth in two distinct developmental phases Experiments have been initiated to investigate the metabolic activities of the shoot apex in both its vegetative and reproductive states Observations are recorded on the terminal meristem of winter rye at a stage when the reproductive state of the apex is being initiated

In the Department of Physiology and Plant Culture much attention has been given to design of growth rooms which will give the highest practical uniformity of light intensity, air temperature, air velocity and relative humidity in the space available for plants Attention has also been directed to maximum flexibility From the experience gained it has been possible to formulate the essential features necessary in such growth rooms These facilities have been used to study the early growth and development of tomatoes In all the conditions tested, plants grown in compost were found to have a higher growth-rate than can be obtained in vermiculite watered with nutrient solution The factors involved are being studied The light/temperature regimes in glasshouses are very important and it is hoped that a detailed study will prove of value in balancing the temperature of the glasshouse (which can be controlled especially at night) with the amount of light received, which cannot be controlled If such a balance could be achieved, a great economy in glasshouse-tomato production would be attained.

A REVISED CLASSIFICATION OF THE LUDLOVIAN SUCCESSION AT LUDLOW

By C H HOLLAND
Bedford College, University of London

J D. LAWSON
University of Birmingham

AND

V G WALMSLEY
University College, Swansea

RECENT detailed studies of the shelf-facies of the Ludlovian at May Hill[1], Usk[2], Woolhope[3,4] and Malvern[5] have revealed a consistent pattern of faunal divisions For some years workers in the Ludlow Research Group have been convinced that the same general pattern obtains in the type area at Ludlow Unpublished work on areas to the west of Ludlow, at Leintwardine (J H McD Whitaker) and Elton (B J Williams), has strengthened this conviction Unfortunately, the published accounts of the type area[6-8] fail to recognize the two most distinctive faunal divisions (Lower Bringewood Beds and Upper Leintwardine Beds of the proposed classification) and leave the other divisions inadequately defined, often in terms of unreliable 'zone fossils', such as *Camarotoechia nucula* and *Dayia navicula* A revision of the geology of the Silurian in the Ludlow district was, therefore, undertaken by us The area investigated extends from Downton Gorge in the west to Ludlow itself and then southwards as far as a line joining Aston and Richard's Castle , it lies between the Leintwardine area to the west and the Elton area to the south-west This work has been completed and a detailed account is being prepared for publication It will include details of localities, faunal lists, and a geological map Standard sections for the classification will be chosen, after discussion with Mr B J Williams and Mr J H McD Whitaker, from the whole area of the Ludlow anticline The detailed description of these sections, excavated if necessary, will include maps, sketches and photographs It has been considered necessary to present this preliminary synopsis of the revised classification in order to facilitate stratigraphical correlation in impending publications on other Welsh Borderland areas of Ludlovian rocks Moreover, several overseas geologists have made extensive collections based on the new scheme and need to refer to it in their publications

The revised classification and its relationship to the existing scheme are shown in Table 1

Table 1

PROPOSED CLASSIFICATION	PREVIOUS CLASSIFICATION
Upper Whitcliffe Beds	Upper Whitcliffe or *Chonetes* Flags
Lower Whitcliffe Beds	Lower Whitcliffe or *Rhynchonella* Flags
Upper Leintwardine Beds	Mocktree or *Dayia* Shales
Lower Leintwardine Beds	
Upper Bringewood Beds	Aymestry or *Conchidium* Limestone
Lower Bringewood Beds	
Upper Elton Beds	Lower Ludlow Shales
Middle Elton Beds	
Lower Elton Beds	

The introduction of new names has not been undertaken lightly and raises a number of problems These nine divisions in the Ludlovian succession are defined essentially on their characteristic faunal assemblages and are therefore biostratigraphical units[9] At Ludlow, because the faunas are to some extent facies faunas, these biostratigraphical units tend to coincide with lithostratigraphical units (divisions defined on the basis of lithological change) Consequently, they are easily mappable divisions and it may be justifiable to consider them as formations, although many stratigraphers insist that formations should be distinguished on lithological criteria alone For the kind of unit with which we are here concerned, the American Commission on Stratigraphic Nomenclature recommends the use of the term 'assemblage zone' It further recommends that such assemblage zones be named after one of the fossils of the assemblage

There are, however, serious objections to this latter practice Taxonomic revision of a fossil name which has been used in this way causes confusion Moreover, the selection of one fossil name from the assemblage is liable to throw undue emphasis on the one chosen, even when it is made clear that it serves merely as a label for a whole fauna Misunderstanding arises especially where, as is often the case, the chosen fossil actually occurs also outside the stratigraphical unit defined In fact, in the succession of faunal assemblages outlined here it would be difficult to find fossils which do not range beyond the limits of one such unit In the absence, at present, of a more satisfactory method of naming such divisions we prefer to use the non-committal term 'Beds' and to distinguish these by appropriate local place names

The *Elton* Beds are named after the village of Elton (*SO* 457 708), in the vicinity of which is the Elton Lane section described by Wood[6] in establishing her Lower Ludlow graptolite zones *Bringewood* Chase is the general name for the highest wooded ground (*SO* 458 733) between Ludlow and Downton Gorge, north of the Ludlow–Wigmore road The name *Leintwardine* (after the village at *SO* 404 740) is preferred to Mocktree[7] because of the possibility of these names being used for stages ending in -ian Finally, *Whitcliffe* (*SO* 508 742) refers to the right bank of the River Teme at Ludlow, the name of which was used by Elles and Slater[7] Its retention seems unlikely to cause confusion , but it is pointed out that these authors included the Ludlow Bone Bed within their 'Whitcliffe Flags', while we, following White[10], regard this distinctive horizon as forming the base of the Downtonian

In Wood's[6] classification of the Lower Ludlow rocks on the basis of their graptolite faunas, the *Monograptus tumsescens* zone is succeeded by the zone of *M leintwardinensis*, which is said to include the Aymestry Limestone, "above which no graptolites are known" Elles and Slater[7], and later Alexander[8], extended the recorded range of *M leintwardinensis* into the Mocktree Shales We have recorded *M tumescens* from the Lower Bringewood Beds of our classification and have found *M leintwardinensis* in the Leintwardine Beds only We know of no confirmable record of *M. leintwardinensis* from below the Leintwardine Beds

The following notes are intended as a brief indication of the essential characteristics of the subdivisions proposed Fossils are listed in each case which are common, fairly common, or characteristically present A few localities are given at which the various beds may be examined

(1) LOWER ELTON BEDS (Approximate thickness 100–150 ft) Soft, poorly bedded, shaly and flaggy, pale olive calcareous siltstones, with layers of limestone nodules The beds often have a speckled appearance due to the presence of numerous shell fragments There is a shelly fauna of Wenlockian aspect, in which small brachiopods and trilobites predominate Graptolites are exceedingly rare, these being the 'Barren Beds' of the Lower Ludlow Shales[8]

Fossils *Atrypa reticularis* (Linnæus), *Chonetoidea grayi* (Davidson), *Dicoelosia [Bilobites] biloba* (Linnæus) (characteristically present), *Leptaena rhomboidalis* (Wilckens), *Resserella [Parmorthis] cf elegantula* (Dalman), *Skenidioides lewisi* (Davidson) (characteristically present), *Dalmanites vulgaris* (Salter), *Beyrichia maccoyana* Jones

Localities (*a*) Overlying Wenlock Limestone in old quarry (*SO* 4725 7300) on south side of Ludlow–Wigmore road, about one mile north-east of Aston Church The soft siltstones of the Lower Elton Beds contrast strongly with the nodular limestones of the top Wenlock Limestone (*b*) Stream section (*SO* 4360 7265) in wood about half a mile north-west of Burrington Church

(2) MIDDLE ELTON BEDS (Approximate thickness 150–350ft) Well-bedded, shaly and thinly flaggy, light olive-grey to yellowish-grey, more or less calcareous siltstones, with smooth, conchoidal fracture Graptolites and orthoconic nautiloids predominate These are the Lower Ludlow Shales of the *Monograptus nilssoni* and *M scanicus* zones of Wood[6]

Fossils *Chonetoidea grayi* (Davidson), *Dalmanites vulgaris* (Salter), *Beyrichia maccoyana* Jones, *Monograptus bohemicus* (Barrande), *M colonus* (Barrande) (common), *M dubius* (Suess), *M nilssoni* (Barrande) (characteristically present), *M scanicus* (Tullberg) (characteristically present), *M uncinatus* (Tullberg), *M varians* (Wood), *Slava [Cardiola] interrupta* (Broderip), orthoconic nautiloids (common)

Localities (*a*) Stream bank (*SO* 4785 7328) about 580 yards south-west of Mary Knoll House (*b*) Exposures in stream referred to under Lower Elton Beds above, for example, at *SO* 4338 7264

(3) UPPER ELTON BEDS (Approximate thickness 150–250 ft) Hard, well-bedded, flaggy, light olive-grey, calcareous siltstones with occasional thin limestone bands These are the Lower Ludlow Shales of the *Monograptus tumescens* zone of Wood[6] and this graptolite is the only common fossil

Fossils *Chonetes lepisma* (J de C Sowerby), *Lingula lata* J de C Sowerby, *Monograptus tumescens* Wood (common and characteristic), orthoconic nautiloids

Localities (*a*) Roadside exposure at Gorsty Farm (*SO* 4785 7355) (*b*) Exposures in steep wooded slope above River Teme (*SO* 431 728), about half a mile north-west of Burrington Bridge

(4) LOWER BRINGEWOOD BEDS (Approximate thickness 160–200 ft) Irregularly bedded, flaggy, pale greyish-olive to greenish grey, calcareous siltstones, with limestone nodules Large brachiopods, particularly strophomenids, are abundant These beds have not previously been distinguished but have probably been included in the Aymestry Limestone

Fossils *Atrypa reticularis* (Linnæus); *Brachyprion* sp nov, *Dalmanella orbicularis* (J de C Sowerby), *Gypidula lata* Alexander, *Leptaena rhomboidalis* (Wilckens), *Leptostrophia filosa* (J de C Sowerby), *Shaleria* sp nov, *Sphaerirhynchia [Wilsonia] wilsoni* (J Sowerby), *Strophonella euglypha* (Hisinger), *Strophonella funiculata* (McCoy), *Dalmanites vulgaris* (Salter), *Poleumita globosa* (Schlotheim); bryozoa

Localities (*a*) Old quarry on south side of Ludlow–Wigmore road (*SO* 4825 7373), about 140 yards north-east of Mary Knoll House (*b*) (*SO* 4940 7265) Sections 200 yards north-west of Sunnyhill Cottages

(5) UPPER BRINGEWOOD BEDS (Approximate thickness 40–150 ft) Hard, irregularly bedded, flaggy and nodular, greenish-grey silty limestones or grey limestones, with thin shaly partings at intervals of several feet The fauna is similar to that of the Lower Bringewood Beds, but strophomenids are less abundant, whereas *Conchidium knightii* and compound corals become common These beds constitute the familiar Aymestry Limestone as seen at Aymestrey and View Edge

Fossils *Atrypa reticularis* (Linnæus) (common), *Conchidium knightii* (J de C Sowerby) (characteristically present), *Gypidula lata* Alexander, *Leptaena rhomboidalis* (Wilckens), *Sphaerirhynchia [Wilsonia] wilsoni* (J Sowerby), *Strophonella euglypha* (Hisinger) (common), *Favosites* sp (characteristically present), *Heliolites* sp (characteristically present), solitary corals, stromatoporoids (characteristically present), crinoid columnals

Localities (*a*) Old quarry (*SO* 4851 7370) at north end of Mary Knoll (*b*) East side of River Teme just south of Bow Bridge (*SO* 4306 7313)

(6) LOWER LEINTWARDINE BEDS (Approximate thickness 100 ft) Flaggy, light olive-grey, calcareous siltstones, with bands of shelly limestone which weather to dark yellowish-brown rottenstones Brachiopods are abundant, but many species characteristic of the Bringewood Beds have disappeared (for example, *Conchidium knightii*, *Gypidula lata*, *Strophonella euglypha*), corals and stromatoporoids are also absent These beds are roughly equivalent to the *Dayia* or Mocktree Shales of Elles and Slater[7]

Fossils *Atrypa reticularis* (Linnæus) (common), *Camarotoechia [Rhynchonella] nucula* (J de C Sowerby), *Chonetes lepisma* (J de C Sowerby) (common), *Dalmanella orbicularis* (J de C Sowerby) (common), *Dayia navicula* (J de C Sowerby) (common), *Leptaena rhomboidalis* (Wilckens), *Lingula lata* J de C Sowerby, *Shaleria ornatella* (Davidson) (common in the higher beds), *Sphaerirhynchia [Wilsonia] wilsoni* (J Sowerby) (common), *Monograptus leintwardinensis* Lapworth (characteristically present)

Localities (*a*) Quarry at Sunnyhill Cottages (*SO* 4954 7253) (*b*) Old quarry (*SO* 4375 7307) at top of wooded scarp of Burrington Hays showing Lower Leintwardine Beds on Upper Bringewood Beds (*c*) Deep roadside quarry (*SO* 4910 7399), about 1,050 yards east-north-east of Mary Knoll House, showing uppermost Lower Leintwardine Beds

(7) UPPER LEINTWARDINE BEDS (Approximate thickness 5–20 ft) Irregularly bedded, flaggy, light olive-grey, calcareous siltstones, with an abundant and most distinctive faunal assemblage There are several trilobite species and an overlap of the brachiopod faunas characteristic of the lower and upper parts of the succession Thin 'biscuity' dark yellowish-brown layers, crowded with *Beyrichia lauensis* and *Chonetoidea grayi* are characteristic of exposures in the western part of the district This important division was not recognized by previous authors but appears to have been for the most part included in the *Dayia* or Mocktree Shales of Elles and Slater[7]

Fossils *Camarotoechia* [*Rhynchonella*] *nucula* (J de C Sowerby), *Chonetes striatellus* (Dalman), *Chonetoidea grayi* (Davidson) (common in the west), *Dalmanella lunata* (J de C Sowerby), *D orbicularis* (J de C Sowerby), *Leptaena rhomboidalis* (Wilckens), *Shaleria ornatella* (Davidson) (common in the east), *Calymene neointermedia* R and E Richter (characteristically present), *Encrinurus* sp, Proetid trilobite, *Beyrichia lauensis* Kiesow (characteristically present)

Localities (*a*) Small roadside exposure (*SO* 4925 7406) about three-quarters of a mile east-north-east of Mary Knoll House (*b*) Small old quarry (*SO* 4542 7370) above Forestry Commission track which leads from (*SO* 4595 7405) near Deepwood southwards, and then westwards across the wooded slopes of Bringewood Chase Other small exposures by this track are at *SO* 4550 7371 and *SO* 4588 7374

(8) LOWER WHITCLIFFE BEDS (Approximate thickness 80 ft) Irregularly bedded, massive or thickly flaggy, olive-grey to dusky-yellow, calcareous siltstones, with occasional calcareous nodules and with contorted siltstones at the top Fossils are not abundant Many of the brachiopods characteristic of the Leintwardine Beds have disappeared and mollusca have become important These beds are the Lower Whitcliffe or *Rhynchonella* Flags of Elles and Slater[7]

Fossils *Camarotoechia* [*Rhynchonella*] *nucula* (J de C Sowerby) (common), *Chonetes striatellus* (Dalman) (small form commonest), *Dayia navicula* (J de C Sowerby) (common in certain beds only), *Fuchsella* [*Orthonota*] *amygdalina* (J de C Sowerby), *Michelinoceras* [*Orthoceras*] *imbricatum* (Wahlenberg), *Serpulites longissimus* J de C Sowerby

Localities (*a*) Roadside exposure (*SO* 4940 7413) just over three-quarters of mile north-east of Mary Knoll House (*b*) Quarry (*SO* 4973 7247) about 300 yards east-south-east of Sunnyhill Cottages, with *Dayia navicula* fairly common (*c*) Old quarry at western side of Hay Mill (*SO* 4348 7351) and exposures in south bank of River Teme east of the mill for about one-third of a mile

(9) UPPER WHITCLIFFE BEDS (Approximate thickness 100 ft) Well-bedded, flaggy, light olive-grey to dusky yellow, calcareous siltstones, with shelly limestone bands Fauna similar to that of the Lower Whitcliffe Beds but brachiopods have become abundant These are the Upper Whitcliffe or *Chonetes* Flags of Elles and Slater[7]

Fossils *Camarotoechia* [*Rhynchonella*] *nucula* (J de C Sowerby) (common), *Chonetes striatellus* (Dalman) (common), *Dalmanella lunata* (J de C Sowerby) (common), *Beyrichia kloedeni* McCoy var *torosa* Jones, *Fuchsella* [*Orthonota*] *amygdalina* (J de C Sowerby), *Pteronitella cf retroflexa* (Wahlenberg), *Michelinoceras* [*Orthoceras*] *bullatum* (J de C Sowerby), *Serpulites longissimus* J de C Sowerby

Localities (*a*) Whitcliffe (*SO* 5095 7415) on right bank of River Teme at Ludlow (*b*) Exposures above eastern bank of River Teme south-westwards from Downton Castle Bridge, for example, at *SO* 4416 7411

EFFECT OF SOME NEUROMUSCULAR BLOCKING AGENTS ON MITOCHONDRIAL ENZYME SYSTEMS

By DR J H KOCH and DR C H GALLAGHER
McMaster Laboratory, C S I R O, Parramatta Road, Glebe, N S W, Australia

THE pyrrolizidine alkaloids lasiocarpine and heliotrine have been shown[1] to block impulse transmission across neuromuscular junctions These alkaloids also inhibit oxidations by pyridine nucleotide-dependent dehydrogenases of liver mitochondria *in vitro*[2] The same structural locus on the alkaloid molecule appears to be responsible for inhibition of impulse transmission and of mitochondrial oxidations As the N-oxides of lasiocarpine or heliotrine affect neither transmission at neuromuscular junctions nor the activity of mitochondrial enzymes, the inhibitory locus is likely to be the nitrogen atom of the cyclic nucleus The neuromuscular blocking action of pyrrolizidine alkaloids resembles the activity of *d*-tubocurarine in certain respects *d*-Tubocurarine contains two quaternary nitrogen atoms as the inhibitory centres and it was of interest to determine whether this alkaloid also inhibited mitochondrial enzyme systems For similar reasons the effect on mitochondria of *dl-tris*-1 10-phenanthroline ruthenium (II) perchlorate [$\mathrm{Ru(phen)}_3^{++}$], a complex ion[3], was investigated

$\mathrm{Ru(phen)}_3^{++}$ has been shown to exert a curare-like effect at the neuromuscular junction[4] This cation is a co-ordinately saturated metal chelate of high chemical stability and does not contain specific active groups or centres Any biological activity which it may have is thus of a physical nature and is referable to the charge it carries[4,5]

In common with lasiocarpine and heliotrine, both *d*-tubocurarine and $\mathrm{Ru(phen)}_3^{++}$ were found to inhibit *in vitro* the activity of mitochondrial enzyme

systems which require pyridine nucleotides for electron transfer The oxidations of citrate, L-glutamate, α-oxoglutarate, L-malate and octanoate, all of which are dependent on pyridine nucleotide, are inhibited by *d*-tubocurarine and Ru(phen)$_3^{++}$ as well as by lasiocarpine and heliotrine On the other hand, the activity of the succinoxidase system which does not require a pyridine nucleotide is increased in mitochondria suspended in 0 25 *M* sucrose by each of the agents

Experimental results are recorded in Table 1 to show the concentrations necessary to produce inhibition of L-malate oxidation, the rate of development and degree of inhibition and the significant reversal of inhibition obtained by supplementing the reaction mixture with diphosphopyridine nucleotide, nicotinamide and reduced glutathione

Clearly these agents inhibit mitochondrial enzyme systems by causing the loss or inactivation of pyridine nucleotides and, possibly, other respiratory co-factors Such an effect could result from increased permeability of mitochondrial membranes allowing diffusion of soluble co-factors from the particles

Mitochondrial permeability may be assessed spectrophotometrically by measuring at 340 mμ the rate of production of reduced diphosphopyridine nucleotide from diphosphopyridine nucleotide added externally to intact mitochondria oxidizing a diphosphopyridine nucleotide-dependent substrate[6,7] The rate of reduction of diphosphopyridine nucleotide is directly proportional to the permeability of the mitochondrial membrane to the passage of diphosphopyridine nucleotide into the particle No effect of heliotrine, lasiocarpine, *d*-tubocurarine or Ru(phen)$_3^{++}$ on mitochondrial permeability could be demonstrated using this system However, it was realized that the experimental conditions were very different from those obtaining in the system used for respiratory experiments Mitochondria re-isolated from a respiratory experiment in which they were subjected to 0 001 *M* *d*-tubocurarine or 0 0067 *M* lasiocarpine were found to be more permeable to the entry of diphosphopyridine nucleotide than incubated control mitochondria More simply, it was possible to demonstrate an effect of the alkaloids on mitochondrial membrane permeability in the following manner Mitochondria equivalent to 800 mgm of fresh rat liver were suspended in 5 ml of 0 25 *M* sucrose containing 0 01 *M* L-malate and 0 001 *M* *d*-tubocurarine or 0 01 *M* lasiocarpine and placed in an incubator at 37° C for 30 min , during which time the temperature of the reaction mixture rose to 32° C The mitochondria were re-isolated by centrifugation after the addition of 35 ml ice-cold 0 25 *M* sucrose and resuspended in 0 25 *M* sucrose or water as required Permeability of the mitochondria was then assessed by the spectrophotometric method[6] Fig 1 shows that incubation in the presence of lasiocarpine or *d*-tubocurarine increases the permeability of mitochondrial membranes to the passage of diphosphopyridine nucleotide The initial differences in optical density at 340 mμ of the curves in Fig 1 are due to reduction of diphosphopyridine nucleotide at different rates during the short time between adding the enzyme and taking the first reading Suspension of mitochondria in water instead of 0 25 *M* sucrose abolishes selective semipermeability of the membranes and also the effect of both the alkaloids

Finally, it was possible to show that mitochondrial permeability increases rapidly under the oxidizing conditions of respiratory experiments and is present at the time oxidative inhibitions by the pyrrolizidine alkaloids, *d*-tubocurarine or Ru(phen)$_3^{++}$ are expressed The observation was made that each of these agents stimulated the oxidation of succinate

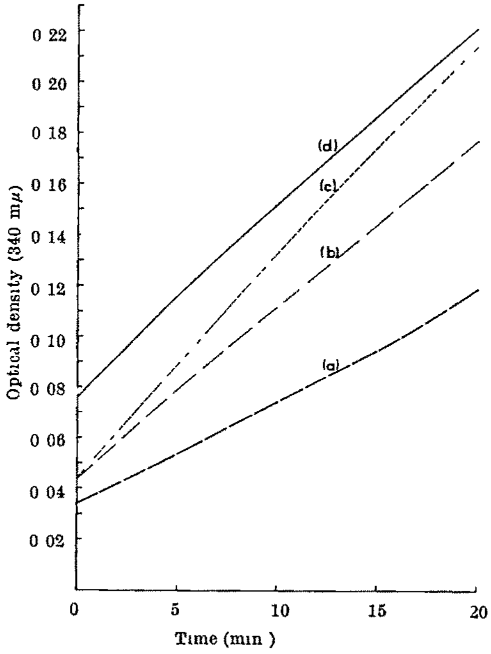

Fig 1 Reduction of diphosphopyridine nucleotide by liver mitochondria in 0 25 *M* sucrose Mitochondria preincubated with (*a*) L-malate 0 01 *M* , (*b*) L-malate 0 01 *M* + *d*-tubocurarine 0 001 *M* , (*c*) L-malate 0 01 *M* + lasiocarpine 0 01 *M* , (*d*) no addition System NaK phosphate buffer, *p*H 7 8, 0 033 *M* , potassium chloride 0 025 *M* , magnesium sulphate 0 0067 *M* , L-malate 0 05 *M* , semicarbazide hydrochloride (neutralized) 0 17 *M* , diphosphopyridine nucleotide 0 0015 *M* , potassium cyanide 0 0002 *M* , enzyme, 50 μl 1 per cent mitochondria (rat liver) in 0 25 *M* sucrose , final volume 3 ml , gas phase air , temperature 22° C

System As Table 1 with succinate 0 01 *M* as substrate and all flask contents in main chamber

by mitochondria in 0 25 *M* sucrose This was thought possibly to be due to increased permeability of mitochondrial membranes allowing the loss of mitochondrial diphosphopyridine nucleotide and thus preventing the production of oxaloacetate which in low concentration inhibits succinic dehydrogenase specifically[8] The suggestion received strong support from the lack of any effect of lasiocarpine, heliotrine or *d*-tubocurarine on succinate oxidation by mitochondria in water, which would not be producing oxaloacetate Conclusive evidence was obtained by the addition of diphosphopyridine nucleotide to mitochondria oxidizing succinate in the presence of each of the agents Diphosphopyridine nucleotide added externally to intact mitochondria enters the particles slowly unless the permeability of mitochondrial membranes is increased Succinate oxidation by mitochondria in 0 25 *M* sucrose was slightly inhibited by the addition of diphosphopyridine nucleotide alone but was rapidly and greatly inhibited by the combination of diphosphopyridine nucleotide and any one of the agents (Table 2) When mitochondria were suspended in water, diphosphopyridine nucleotide produced maximum inhibition of succinate oxidation alone and lasiocarpine, heliotrine or *d*-tubocurarine did not affect the rate of oxidation when added to systems with or without diphosphopyridine nucleotide Similarly, the addition of 0 0004 *M* Ca^{++} to mitochondria in 0 25 *M* sucrose stimulates succinate oxidation by increasing mitochondrial permeability and facilitates penetration of the particles and inhibition by added diphosphopyridine nucleotide

Table 2 shows typical experiments with *d*-tubocurarine and lasiocarpine, similar results were obtained with heliotrine and $\mathrm{Ru(phen)}_3^{++}$ It is clear that each of the agents increases the permeability of mitochondrial membranes to the entry of diphosphopyridine nucleotide

The effect of pyrrolizidine alkaloids, *d*-tubocurarine and $\mathrm{Ru(phen)}_3^{++}$ on mitochondrial diphosphopyridine nucleotide is being investigated and will be reported elsewhere

It is thus shown that these three types of chemically dissimilar compounds have actions in common on neuromuscular junctions and on liver mitochondria At each site selective semi-permeable membranes are involved We suggest that the mechanism of action of the agents may be identical at the neuromuscular junction and on mitochondrial membranes and, further, that, as the biological activity of $\mathrm{Ru(phen)}_3^{++}$ is due only to the charge carried, the activities of pyrrolizidine alkaloids and *d*-tubocurarine may also be referable to the charge carried on the nitrogen atoms

We wish to thank Dr Price and Dr Culvenor, of the Chemical Research Laboratories, for preparing the pyrrolizidine alkaloids, and Dr Dwyer, of the National University, Canberra, who prepared *dl-tris*-1 10-phenanthroline ruthenium (II) perchlorate We acknowledge gratefully the skilled and careful technical assistance of Miss Flint-Gallé and Miss Mann

EFFECT OF DIETARY FAT AND EXTENT OF BLOOD SAMPLING ON THE LEVEL OF PLASMA CHOLESTEROL IN THE RAT

By I. COLEMAN* and J M R. BEVERIDGE

Department of Biochemistry, Queen's University, Kingston, Ontario, Canada

IN the course of an investigation of the effect of certain dietary fats on the plasma cholesterol-level of the white rat, increases in the level of this substance were found which were at first attributed to the effect of dietary fat but which, on further study, were found to be due to the combination of this component and the frequency and extent of blood sampling

Male white rats were placed on formula diets similar to those used by Beveridge *et al* [1] in studies on man Fat supplied 28 4 and 58 5 per cent total calories, protein, 16 9 per cent Plasma cholesterol determinations were made by the method of Sperry and Webb[2] modified to permit duplicate determinations on 0 1 ml of rat plasma Blood samples were taken by tail section, using powdered heparin as the *in vitro* anticoagulant

In Table 1 are shown the effects of varying dietary fat and blood sampling procedure on plasma cholesterol-levels In experiment 1, groups maintained on a high and a moderate fat intake were compared with those receiving their stock diet of 'Purina' fox chow Blood samples of 2–3 per cent of total blood volume were taken from all groups on alternate days for the first 8 days, and weekly thereafter At the end of 35 days of feeding, the groups receiving corn oil showed a highly significant increase in plasma cholesterol, while those on fox chow remained unchanged. The group receiving a high fat intake

Table 1 EFFECT OF DIETARY FAT AND EXTENT OF BLOOD SAMPLING ON PLASMA CHOLESTEROL-LEVEL IN THE RAT

Experiment No	Blood sampling procedure	Diet	Number of animals	Initial mean plasma cholesterol (mgm /100 ml)	Duration of test (days)	Final plasma cholesterol (mgm /100 ml)	Av group percentage change	*P*
1	Blood sample of 2 per cent blood volume taken on alternate days for the first 8 days and weekly thereafter	*HC* *MC* Chow	14 14 14	80 5± 6 9 75 7± 9 3 76 4± 9 5	35 35 35	96 5±12 3 86 2± 9 9 76 6± 7 8	+20 5 +13 5 +0 3	<0 01 <0 01 Non-sig
2	Blood sample of 0 5–1 0 per cent blood volume taken on first and final days only	*HC* *FF*	30 30	64 8±12 4 75 4± 9 4	14 14	64 6±12 4 70 2±12 4	−0 3 −6 9	Non-sig Non-sig
3	Blood sample of 1–1 5 per cent blood volume taken on alternate days for 6 days	*HC* *FF*	20 20	73 7±11 1 71 8±11 7	6 6	96 6±10 7 78 8±15 7	+31 1 +9 8	<0 01 Non-sig
4	Blood sample of 2 5–4 per cent blood volume taken on alternate days for 6 days	*HC* *FF*	15 15	67 2±14 3 67 7±12 8	6 6	150 0±18 0 107 7±27 2	+122 4 +59 0	<0 01 <0 01

Diets used *HC*, corn oil, 58 5 per cent cal , *MC*, corn oil, 28 4 per cent cal , *FF*, essentially fat-free , Chow, 'Purina' fox chow

demonstrated an increase of 20 5 per cent, while those on a moderate intake increased only 13 5 per cent during this period, the difference being highly significant

This elevation in plasma cholesterol of the groups fed corn oil was paralleled by other groups receiving formula diets containing butter, beef dripping, coconut oil and corn oil supplemented with cholesterol to equal the concentration present in butter (not here reported) In each case the elevation in plasma cholesterol was dependent on the concentration at which the fat was fed and not upon the nature of the fat Because of the consistency of the hypercholesterolæmia with all fats examined and the gradation of response in proportion to the level at which the fats were supplied, it appeared certain that the increase in plasma cholesterol was dependent solely upon the presence of dietary fat

However, repetition of the study in the second experiment, in which the group fed corn oil was compared with the more suitable control group consuming fat-free formula rather than fox chow, failed to reveal any change in plasma cholesterol after 14 days The animals had blood samples of 0 5–1 0 per cent of total blood volume removed only at the start and conclusion of the test The only difference in the conditions of the first two experiments that appeared to offer any rational basis of explanation for the apparently divergent results was the difference in the extent and frequency of blood sampling This was, at first regarded as unlikely, since no reports of hæmorrhage causing a lipæmia in the rat similar to that described for the rabbit and guinea pig could be found in the literature

However, in experiment 3, a group of rats fed a diet supplying 58 5 per cent of total calories in the form of corn oil was compared with a similarly matched group on a fat-free diet Both were subjected to bleeding on alternate days for a period of 6 days, during which blood samples of 1–1 5 per cent of total blood volume were taken The group on the high-fat ration showed an increase in plasma cholesterol of 31 1 per cent during this period, while those on the fat-free diet showed no significant change An increase in the amount of blood taken to 2 5–4 per cent of total blood volume, in experiment 4, produced an increase in plasma cholesterol of 122 per cent in the animals on the high fat intake Even animals on the fat-free diet showed an increase of 59 per cent

It was now apparent that the hypercholesterolæmia found in experiment 1 could not be attributed to an uncomplicated response to dietary fat, but was the product of both dietary fat and the degree of hæmorrhage to which the animals were subjected Under conditions of low bleeding stress, a high fat diet, as in experiment 2, caused no change in plasma cholesterol When bleeding was increased to 1–1 5 per cent of total blood volume on alternate days for 6 days (experiment 3), a high corn oil diet produced a significant increase in plasma cholesterol, although the animals on a fat-free diet and under the same conditions of bleeding showed no change Thus the hypercholesterolæmia is a combined effect of diet and hæmorrhage When bleeding stress was increased to 2 5–4 per cent of blood volume on alternate days for 6 days, highly significant increases in plasma cholesterol resulted in both the high-fat and fat-free groups These results, therefore, clearly indicate that the hypercholesterolæmia due to severe hæmorrhage does not depend solely on the presence of dietary fat although it is augmented by the latter

This response of the rat to bleeding stress and dietary fat has not, to our knowledge, been previously reported It is suggestive of the lipæmia of hæmorrhage obtained in the rabbit[3,4] and guinea pig[5,6] There is a difference, however , Spitzer[7], on investigating the lipæmia produced in rabbits on a high-fat diet, found it necessary to bleed to 10–15 per cent of blood volume on successive days to elicit the response, and also found that the animal recovered in about the same time necessary to induce the hyperlipæmia The rats were never bled more severely than 2 5–4 per cent of blood volume on alternate days to produce the hypercholesterolæmia on high-fat diets, and from experiment 1 there is evidence that these elevations in plasma cholesterol are maintained for periods of time as long as 5 weeks after the period of severe bleeding

Although no substantiated explanation of this phenomenon can be advanced at the present time, we wish to bring it to the attention of other workers in this field as a possible explanation of some of the conflicting reports on the effect of dietary fat on the plasma cholesterol-level of the rat

NONHÆM IRON IN ERYTHROCYTES AS A PRECURSOR FOR HÆMOGLOBIN

By Dr. M FABER and Dr I FALBE-HANSEN

Finsenlaboratoriet, Finseninstitutet og Radiumstationen, København

THE existence of nonhæm iron in erythrocytes from peripheral blood has long been a matter of dispute The presence of iron receptors has been suggested by Walsh *et al*[1] and Jandl *et al*[2] have shown in experiments with radioactive iron that reticulocytes take up iron *in vitro* and that this iron is bound to the stroma and incorporated into hæm Recently, Bernard *et al*[3] and Lambrechts and Thimus[4] have found nonhæm iron fairly constantly in erythrocytes from normal and pathological human blood as the difference between total iron and hæmoglobin iron The presence of nonhæm iron in the stroma of immature red cells in bone marrow has been demonstrated by electronmicroscopy[5,6]

The purpose of the present work has been to verify the existence of nonhæm iron in the stroma of normal, mature red cells and demonstrate its significance in hæmoglobin synthesis by means of *in vivo* experiments with radioactive iron

A modification of the method of successive hæmolysis used by Hillier and Hoffman[7] for preparation of hæmoglobin-free red cell 'ghosts' for electronmicroscopy was chosen The ghosts appeared greyish-white, and no hæmoglobin could be demonstrated spectrophotometrically, but there was still a faint positive benzidine reaction

Estimations of stroma iron were carried out on blood samples taken for ten successive days from a patient with recently diagnosed genuine hæmochromatosis The disease was mild, and the patient may be regarded as hæmatologically normal The iron contents of ghosts prepared from 16 ml of packed red cells ranged from 41γ to 125γ with an average of 76γ A few determinations on ghosts from normal humans and rabbits gave values within the above-mentioned limits

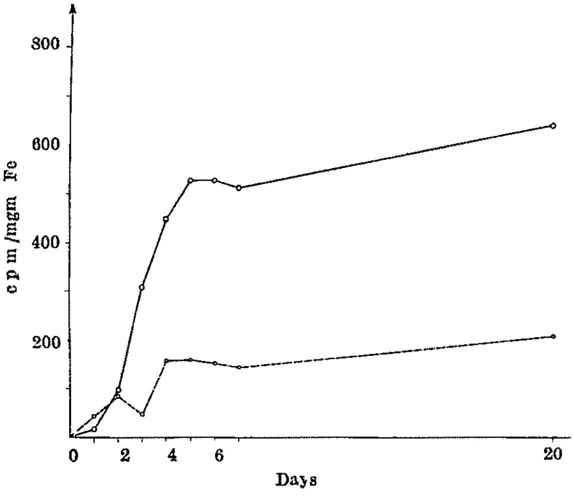

Fig 1 Incorporation of iron-59 in hæmoglobin and stroma iron in a patient with genuine hæmochromatosis ○—○, hæmoglobin iron, ○- - -○, nonhæm iron

In order to estimate the significance of this stroma iron in hæmoglobin synthesis this patient was given 8 5 μc iron-59 intravenously Blood samples were taken daily, and after determination of the amount of stroma iron, this was electroplated on copper disks and the β-radioactivity measured by a Geiger–Muller tube As will be seen from Fig 1, the specific activity of the stroma iron was higher than that of the hæmoglobin iron on the first day after administration of iron-59, but lower on the following days, quickly reaching constant values of about one-third of the specific activity of hæmoglobin iron Owing to the very low counting rate on the first day it was deemed necessary to explore this early phase further

Four female rabbits of the same age and weight were injected intravenously with about 10 μc iron-59 each The animals were killed after 1, 2, 5 and 22 hr, respectively, and a sufficient amount of blood to provide 16 ml of packed erythrocytes was obtained from each animal Stroma iron and radioactivity was determined as previously The results appear in Table 1

Table 1

Hours after injection of iron-59	Stroma iron in γ per 16 ml packed erythrocytes	Specific activity of stroma iron (c p m /mgm iron)	Specific activity of hæmoglobin iron (c p m /mgm iron)
1	84	550	370
2	98	13,540	3,780
5	75	2,020	5,750
22	80	2,060	9,190

There is a very high rate of incorporation in the stroma iron of the erythrocytes released during the first hours, but already after 5 hr the specific activity of hæmoglobin is higher than that of stroma iron These findings strongly support the view that stroma iron acts as an intermediate between transport iron of plasma and hæmoglobin

That this transfer mechanism may be blocked artificially appears from the results of Bénard *et al*[8] and Jandl *et al*[2], who show by means of iron-59 that there is practically no synthesis of hæm *in vitro* in blood containing lead ions That a similar blocking may be an important factor in certain anæmias is seen from an experiment performed on a patient with severe anæmia, characterized, after splenectomy, by a considerable amount of siderocytes in the peripheral blood. The anæmia was probably of the type described by Dacie *et al*[9] This patient was given 14 3 μc iron-59 intravenously and a week later the specific activities of stroma iron and hæmoglobin iron were estimated Despite the considerable period of time which had elapsed since the administration of iron-59 the specific activity of stroma iron was more than four times higher than that of hæmoglobin iron, the specific activities being 1,660 c p m /mgm iron and 360 c p m /mgm iron, respectively This strongly supports the view that blocking of the transport system of iron in the stroma of red blood cells may play an important part in this anæmia

The chemical nature of the stroma iron is still unknown , but experiments which are in progress in this laboratory indicate that it may at least in part, consist of ferritin

EXTREME SENSITIVITY OF GERMINATION AND PHOTOPERIODIC REACTION IN THE GENUS *CHENOPODIUM* (TOURN.) L.

By DR. BRUCE G. CUMMING

Plant Research Institute, Central Experimental Farm, Ottawa

PLANTS of *Baeria chrysostoma*[1] and *Pharbitis nil*[2] are known to respond to photoperiod at a very early stage in growth *Chenopodium rubrum* L is particularly valuable as an experimental plant since floral initiation can occur very rapidly when seed is germinated under 8-hr short days in Petri dishes[3] In addition, one photo-inductive short day may initiate floral formation (as shown in *Xanthium pennsylvanicum*[4] and *Pharbitis nil*[2]), while, in germination, there are red/infra-red and red/blue reversal effects (as shown in lettuce[5,6]) Furthermore, there is marked sensitivity to temperature in germination

Detailed comparisons of flowering have been made between selections of four species of *Chenopodium* (*a*) *C rubrum* L , (*b*) *C salinum*, Standley (syn *C glaucum* var *salinum* (Standley) Boivin) , (*c*) *C glaucum* L (syn *C glaucum* L var *glaucum* Aellen) , (*d*) *C album* L Under 8-hr short days, with alternating temperatures of 15° C for 16 hr in darkness and 25° C for 8 hr in light of 1 200 foot-candles (fluorescent combined with incandescent), that is, 15–25° C , the least number of days from seed imbibition (on moistened filter paper in Petri dishes) to visible floral formation, has been, in species (*a*) 6, (*b*) 12, (*c*) 20, (*d*) 36 The corresponding minimum true leaf numbers were in species (*a*) 2, (*b*) 2, (*c*) 2–4, (*d*) 4 Alternating temperatures of 15–25° C to 20–30° C are optimal for floral initiation in these species Floral initiation may occur under intensities as low as 150 foot-candles (fluorescent combined with incandescent), although less rapidly Fig 1*a* illustrates 100 plants of *C rubrum* 17 days after imbibition under 8-hr short days, with light of 250 foot-candles (fluorescent), alternating temperature 15–25° C , 90 per cent of the plants showed floral formation Fig 1*b* illustrates one of these plants when 21 days old , the two true leaves and four perianth members were very rudimentary , there were no stamens but the ovary produced a single viable seed after cross-pollination

Nutrients markedly influence the amount of growth and floral formation, but the response is different between species For example, under 8-hr short days with light of 1,200 foot-candles (fluorescent combined with incandescent) and alternating temperature of 23–28° C , the minimum true leaf numbers of plants grown in Petri dishes, with water as compared with Hoagland's solution, were, in species (*a*) 2 versus 2, (*b*) 2 versus 4, (*c*) 2–4 versus 4–6, (*d*) 4 versus 9–10, respectively Soil gave results similar to Hoagland's solution with an even greater leaf number occurring in *C album* The amount of floral formation was also proportionately much greater when nutrients were supplied, and stamen formation occurred even on some plants of *C rubrum* (Fig 1*c*) These results provide further evidence that the concept of minimum leaf number must be treated with circumspection[7]

Wide differences in photoperiodic sensitivity between these species are shown under 20-hr long days or continuous light, when plants are grown in soil *C album* and *C glaucum* will flower, although less rapidly than under short days In contrast, *C rubrum*, under 20-hr long days, at a temperature of approximately 24° C , has remained vegetative indefinitely (that is, at least 200 days , Fig 1*d*) With increased age *C rubrum* becomes increasingly sensitive to photoperiod and one photo-inductive cycle, that is, one 16-hr dark period following an 8-hr light period, may initiate floral formation—

Table 1 PER CENT GERMINATION OF (*a*) *C rubrum*, (*b*) *C salinum*, (*c*) *C glaucum*, (*d*) *C album*, IN DARKNESS AND UNDER 8-HR SHORT DAYS WITH CONSTANT AND ALTERNATING TEMPERATURES , 10 DAYS AFTER IMBIBITION

Temperature	Darkness (*a*)	(*b*)	(*c*)	(*d*)	8-hr short days (*a*)	(*b*)	(*c*)	(*d*)
Constant

Alternating								
25–35° C	25	15	93	40	100	60	98	70
20–30° C	85	50	90	85	100	90	98	88
15–25° C	95	15	95	68	100	75	75	80
10–20° C	100	0	90	93	100	30	98	80

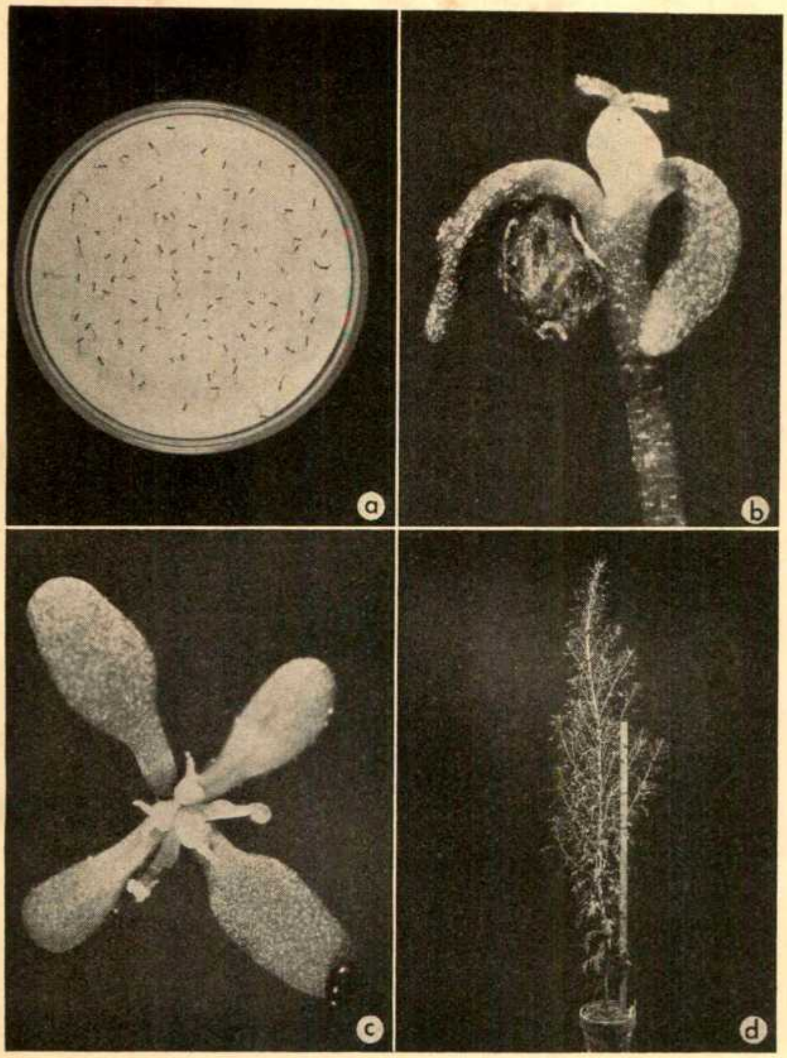

Fig. 1. *C. rubrum* L. *a*, 100 plants 17 days old, 0·8 cm. tall, 90 per cent flowering in 9 cm. × 2 cm. Petri dish ; 8-hr. short days, 250 ft.-c. (fluor.), alternating temperature 15–25° C. *b*, Flowering plant 21 days old, from *a* ; original pericarp and testa 0·6 mm. diam. still attached to cotyledon. *c*, Stamens and ovaries on plant grown with Hoagland's solution, 8-hr. short day, 1,200 ft.-c. (fluor./incand.), alternating temperature 23–28° C. ; original testa 0·6 mm. diam. *d*, Vegetative plant 200 days old, 20-hr. long days (scale : 1 m. rule)

especially if the prevailing light intensity is 2,000 foot-candles or more. With one photo-inductive cycle, depending on age and treatment, floral formation may be imperfect or delayed 6–8 weeks. Floral formation is increased in rate and amount with increase in the number of photo-inductive cycles and, under favourable conditions, it may be visible microscopically in 3–4 days and macroscopically in 6–7 days.

C. salinum appears to be intermediate between *C. glaucum* and *C. rubrum* in sensitivity to photoperiod and, while some selections have flowered within about 120 days, under 20-hr. long days, others have remained vegetative indefinitely (that is, at least 200 days). Induction of floral formation in *C. salinum* can be accomplished with one photo-inductive cycle—at an earlier stage of growth than in *C. rubrum*.

When sensitivity is evaluated by the amount of germination under different light qualities, energies, time sequences and temperatures, the species are again listed in order of sensitivity as $(a) > (b) > (c) > (d)$. Table 1 summarizes the percentage germination of non-dormant seed under constant and alternating temperatures, in darkness as compared with 8-hr. short days (250 foot-candles—fluorescent). In continuous light, germination was similar to that under 8-hr. short days. Germination of *C. rubrum* was negligible in darkness at constant temperatures $< 35°$ C. and under 8-hr. short days at constant temperatures $< 25°$ C. The lower alternating temperatures completely substituted for the light requirement in *C. rubrum* but not in *C. salinum*. Seeds of *C. rubrum* and *C. salinum* when exposed for 1 min. to white light of 50 foot-candles (fluorescent) 10 days after imbibition in darkness, germinated equally as well as under 8-hr. short days. In darkness at a constant temperature of 25° C., transfer of seeds to 10° C. for one 8-hr. period, 10 days after imbibition, initiated 100 per cent germination of *C. rubrum* and 50 per cent of *C. salinum*.

In species (a)–(d) germination can be promoted by white or red and inhibited by blue or infra-red radiation. In *C. rubrum*—the most sensitive species—at a constant temperature of 35° C., using appropriate filters and fluorescent combined with incandescent white light (1,200 foot-candles), 1 min. of white or red light supplied 8 hr. after imbibition may initiate 100 per cent germination, while 1 min of blue or infra-red radiation may completely inhibit germination ; red/infra-red and red/blue reversal effects are similar to those reported for lettuce[5,6].

These and other unpublished results that will be reported elsewhere indicate that the genus *Chenopodium* offers valuable and diverse material for experimental study. There is some evidence to support the postulation that 'weediness' of these species may be positively correlated with the amount of phenotypic 'plasticity' and with absence of sensitivity in germination and photoperiodic response. In order of distribution as weeds in Canada the species would be evaluated as *C. album* > *C. glaucum* > *C. salinum* > *C. rubrum*.

I am indebted to Dr. H. A. Senn, director of the Plant Research Institute, for the availability of extensive controlled environmental facilities, and to Dr. T. F. Cuddy, of the Plant Products Division, for the use of precisely controlled germination cabinets.

REDOX POTENTIALS IN SOYBEAN NODULES DURING THE VEGETATIVE PERIOD

By DR. HELENA EBERTOVÁ

Research Institute for Plant Production, Prague, Czechoslovakia

THE attention of research workers is becoming more and more concentrated upon biochemical oxidation-reduction processes taking place during the fixation of molecular nitrogen. Rabotnova[1] established that redox potentials of leguminous root nodules are comparatively low, the *r*H-value being about 17–19. Fedorov[2], in his theory of nitrogen-fixation, also emphasizes the active role taken by various enzymatic systems under low *r*H-values. In connexion with these findings studies on the respiratory systems of rhizobia, nodules and leguminous plants require special attention. Bergersen[3] found no substantial differences between the respiratory activity of cultivated rhizobia and bacteroides from nodules during their development. Allison, Ludwig, Minor and Hoover[4] carried out respiration tests with nodules and leguminous plant roots and concluded that rhizobia in nodules are relatively inactive as regards respiration and carbohydrate consumption. The value of redox potential in nodules also represents an important condition for the activity of hydrogenase, which is regarded as having an essential part to play in the fixation of nitrogen. The role of hydrogenase in the fixation processes has been investigated by many authors, for example, Wilson, Burris and Coffee[5] and recently Hamilton, Shug and Wilson[6].

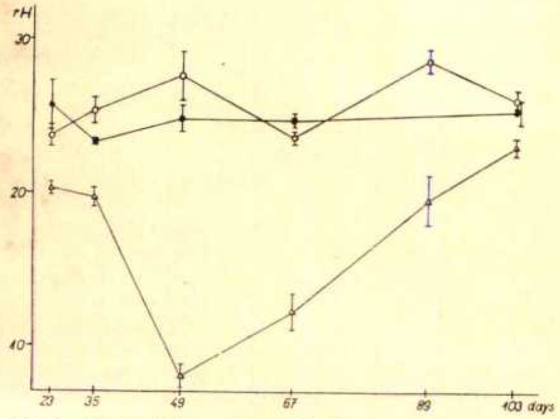

Fig. 1. *r*H values in soybeans: ○—○, stems; ●—●, roots; △—△, nodules. Standard deviation, I; abscissa, number of days after sowing

In the present work the course of the redox potential and *p*H-value in stems, roots and nodules has been followed during the whole period of vegetation and related to the increase in the number and size of nodules. Both redox potential and *p*H-value have been measured in three replicate plants with platinum and antimony micro-electrodes respectively, thrust directly into the plant organs. On each plant one nodule was chosen for the measurements. A saturated calomel half-cell was used for reference; the tests were carried out in the air. For greater simplicity in preparing graphs and easier comparison with other authors' results, the redox potential values are expressed by means of an *r*H scale (Fig. 1). As Hewitt[7] reports reasons against using the term *r*H in biological systems such as these, the ranges of measured E_h and *p*H values are also quoted in the text.

The results of the *r*H field-tests measured in plants dug up at convenient intervals are presented in Fig. 1. In the greenhouse similar results have been obtained with plants grown in sand with mineral nutrients containing 1/20 of nitrogen ratio. At suitable intervals the plants of single pots (3 plants per pot) were taken for potential measurements and estimation of nodulation and total nitrogen in plant material by the Kjeldahl method. Then the nitrogen fixation ratio in the glasshouse experiment could be calculated. Decrease of potential was observed in nodules of the same age as those in the field experiment.

Fig. 2 shows the numbers and sizes of nodules in the field-experiment during the whole period of vegetation. Until the ripening of the plants, new pink nodules originated constantly under field, as well as under greenhouse, conditions. Their *r*H values were about 10 and their ability to fix nitrogen was high, as was proved by estimation of total fixed nitrogen content in each pot in the glasshouse and by the concentration of total nitrogen in single plant organs in the field. Nitrogen fixation and nitrogen content are given in Fig. 3. Differently coloured nodules in various stages of development and with *r*H values differing by up to 13 units have been simultaneously found in the root system of one and the same plant, even on the roots of plants 103 days old. Thus, if the curve of *r*H values had to represent the actual course of the redox potential during the life of the nodule, it was always necessary to pick out for measurement only the oldest nodules in the root system of experimental plants. In the soybean root system in all our experiments nodule formation began very early, and always on the upper part of the main root. These first nodules grew very quickly and reached about ¼ in. diameter and their content became pink during

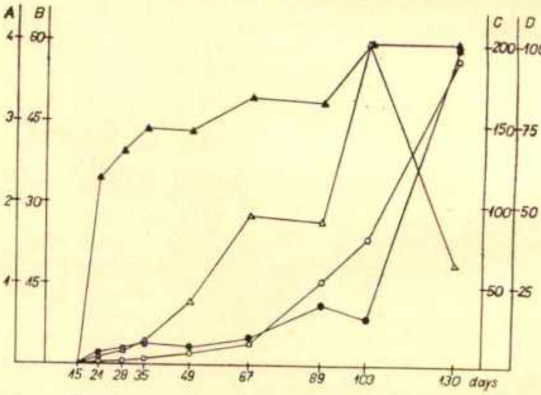

Fig. 2. Formation and growth of nodules. *A*, ○—○, volume of nodules on one plant (c.c.); *B*, ●—●, number of nodules on one plant; *C*, △—△, average volume of one nodule (µl.); *D*, ▲—▲, percentage of nodulation. Abscissa, number of days after sowing

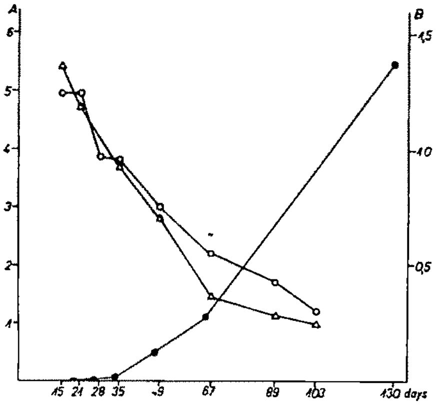

Fig 3 Nitrogen fixation and nitrogen content in plants *A*, ○—○, percentage of total nitrogen in leaves of the field plants inoculated, △—△, controls, *B*, ●—●, nitrogen (gm) fixed per pot in glasshouse Abscissa, number of days after sowing

the maximum decrease of potential, whereas other nodules scattered throughout the root system appeared and reached their largest size much later The oldest nodules for the measurements could therefore be easily picked out according to their location, size, colour and also their consistence

The tissue of the nodules differed from that of other parts of the plants not only in regard to its redox potential but also in *p*H value During the period of low redox potential (about −200 mV), the *p*H of the pink nodules varied between 7 2 and 8 7, whereas in the roots and stems it was 5 9–6 9 (potentials about + 350 mV) No differences were found between *E*h and *p*H values measured in roots and stems of inoculated and control plants

These results are evidence that the nodules on leguminous plants with quickly growing root systems originate on secondarily thickened parts of roots without root hairs and without primary cortex The appearance of new active nodules is not limited by the advancing age of the host plant, almost up to the ripening of the fruits Different values of redox potentials simultaneously measured in nodules of a single plant are in accordance with this observation The *r*H values reflect only the physiological state and age of nodules irrespective to a large degree of the age of the host When comparing the results plotted in Figs 1 and 3, we can see that a considerable fall of potential in the first nodules coincides with the beginning of nitrogen fixation observed in greenhouse and field-tests The differences in size and colour between the control and inoculated plants in the field were observed to run parallel with nitrogen content in leaves also from the seventh week after sowing

A further interesting result is that the redox potential is, to a large degree, not conditioned by the size of the nodules The size of nodules picked out for potential measurements in carrying out the field-tests was about 200 µl and remained unchanged from the beginning of fixation until the plants ripened , the observations in the greenhouse were made on nodules of about a fifth that size, but with similar results as regards absolute values and development with time

Very low values of potentials in nodules fixing atmospheric nitrogen are not opposed to the hypothesis that reduction of molecular nitrogen in nodules by hydrogen is catalysed by hydrogenases The large differences between *r*H values in various soybean organs and in nodules is evidence of specific biochemical processes taking place in the nodules during the fixation of nitrogen and show that nodules cannot be regarded as ordinary organs of the plant, as might be deduced from the experiments on rates of respiration of nodules[4]

PHOTOREACTIVE PIGMENTS IN FLAGELLATES

Chromoprotein Pigments of Some Cryptomonad Flagellates

By Dr. MARY BELLE ALLEN, Dr. ELLSWORTH C. DOUGHERTY, and Dr JOHN J A McLAUGHLIN

Laboratory of Comparative Biology, Kaiser Foundation Research Institute, S 14th St and Cutting Blvd , Richmond, California , and Haskins Laboratories, 305 East 43rd St , New York City

THE cryptomonad flagellates are a little-known group of organisms comprising both pigmented and apochlorotic forms The pigmented forms are usually blue-green, brown, purple or red in colour and are capable of photosynthesis Until very recently, nothing was known of the pigments responsible for these colorations—the only information on record before the present work[1,2] being a personal communication from Haxo and Wolken to Provasoli[3], that *Rhodomonas lens*, a red cryptomonad, contains a phycobilin-like pigment The present communication describes water-soluble chromoprotein pigments from two blue-green cryptomonads, *Chroomonas* sp and *Hemiselmis virescens*, and a brown representative, *Cryptomonas ovata* var *palustris*

Chroomonas sp , kindly supplied by Prof E G Pringsheim, was examined in 1953 This organism could only be grown in soil–water medium and was not available in sufficient quantity for more than the measurement of the absorption spectra of whole cells and crude extracts

More extensive measurements have been made on the pigments of two other cryptomonads *Hemiselmis virescens*, obtained from Dr Michael Droop, was grown on the synthetic medium 'DC' (ref 4) Dense growth was obtained using light intensities of 1,000–1,500 lux at a temperature of 18° C Cultures were grown for twenty days in 5-litre Fernbach flasks containing 1 5 l of medium Optical densities of 2 5 were obtained by aerating the cultures

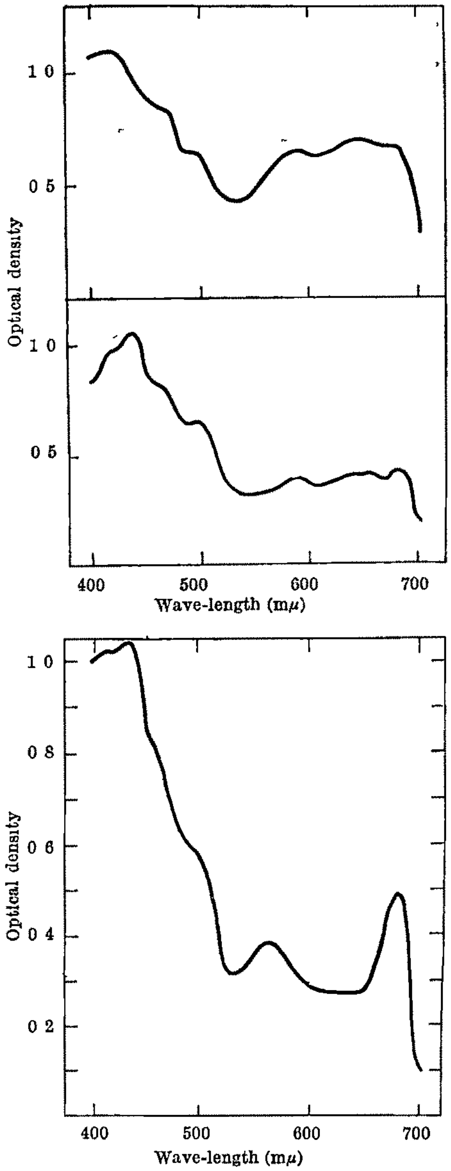

Fig 1 (*a*) Absorption spectra of cell suspensions of *Hemiselmis virescens* (top) and *Chroomonas* sp (bottom) (*b*) Absorption spectrum of cell suspension of *Cryptomonas ovata*

Cryptomonas ovata var *palustris* was obtained from Dr Richard C Starr and grown on the proteose peptone medium recommended by him[5] The light intensity during growth was approximately 800 lux, provided by a screened bank of white fluorescent lights *C ovata*, like the other cryptomonads investigated, did not grow in strong light The temperature was 23–28° C *C ovata* multiplied very slowly under these conditions , from four to six weeks was required to obtain a dense culture

For extraction of the pigments, cells were centrifuged from the culture medium and washed, and the packed cell mass frozen and thawed, or allowed to stand a few hours in the refrigerator at 5° C in the presence of a few drops of toluene Either treatment resulted in the extraction of water-soluble pigments from the cells The cell debris was separated from the extracted pigments by centrifugation at 25,000*g*

Absorption spectra of cell suspensions were measured in a Cary recording spectrophotometer, using the opal glass technique of Shibata *et al* [6] to overcome the effects of scattering Absorption spectra of the extracted pigments were measured with a Beckman *DU* spectrophotometer

Attempts at chromatographing the pigments were made according to the procedure described by Swingle and Tiselius[7] and Haxo *et al* [8]

Absorption spectra of suspensions of intact cells of *Chroomonas* sp , *H virescens* and *C ovata* are shown in Figs 1*a* and 1*b* The absorption spectra of *Hemiselmis* and *Chroomonas* are different from those of any organisms previously studied, whereas the spectrum of *C ovata* resembles that of a blue-green alga containing phycoerythrin

Disruption of *H virescens* releases a blue pigment with a deep red fluorescence The absorption spectrum of this pigment is shown in Fig 2 This three-peaked absorption curve, with maxima at 645, 620–625 and 580 mμ, is different from that of any algal chromoprotein previously reported Attempts at resolving the pigment into components by chromatography have led to loss of most of the pigment on the column The portion recovered had the same absorption spectrum as the original material. Attempts at separation into sub-units by fractional precipitation with ammonium sulphate have been equally unsuccessful The blue pigment from *Hemiselmis* is thermolabile, non-dialysable, and precipitated by acetone or ammonium sulphate The few measurements which could be made on *Chroomonas* suggest that its blue pigment is similar to that of *Hemiselmis*

On disruption of the cells, a red pigment with orange fluorescence is released from *C ovata* The absorption spectrum of this pigment is shown in Fig 3 The peak at 565 mμ is reminiscent of C-phycoerythrin[8], but the shape of the curve is different, falling less sharply on the long-wave-length side than does C-phycoerythrin, and having a shoulder at 600 mμ Like the blue pigment from *Hemiselmis*, the red pigment of *Cryptomonas* is thermolabile, non-dialysable, and precipitated by acetone and ammonium sulphate at high concentrations Attempts at purification by chromatography on calcium phosphate gel led to decomposition of the pigment Chromatography on calcium carb-

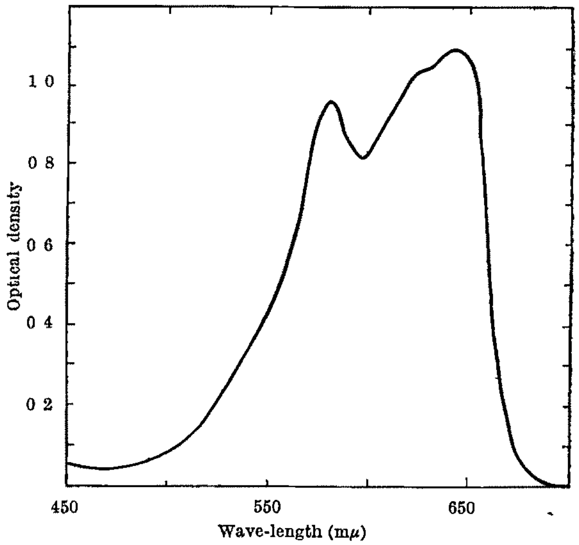

Fig 2 Absorption spectrum of blue pigment from *Hemiselmis virescens*

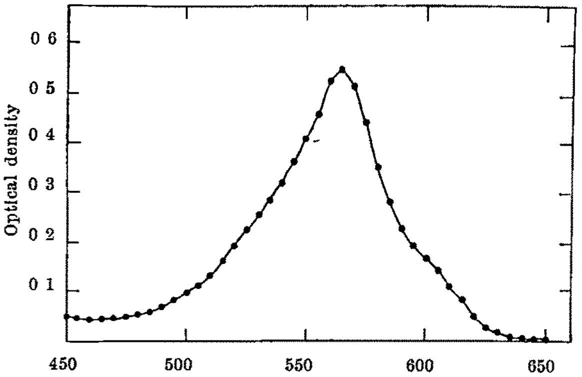

Fig 3 Absorption spectrum of red pigment from *Cryptomonas ovata*

onate was also tried, but the pigment passed through the column without being absorbed

The spectroscopic and other properties of the red and blue cryptomonad pigments are consistent with the conclusion that they are bilichromoproteins similar to, but not identical with, those found in the red and blue-green algae This conclusion is supported by some preliminary observation on the products resulting from hydrolysis of the proteins with hydrochloric acid as described by Ó hEocha[9] Some differences from the phycobilins of the red and blue-green algae must be noted, however The cryptomonad pigments are more labile under chromatography than phycobilins previously known, they require very high concentrations of ammonium sulphate to precipitate them, and they are quite resistant to hydrolysis by hydrochloric acid Studies by Haxo and Fork and by Ó hEocha and Raftery[2] have shown spectroscopically different chromoprotein pigments in other cryptomonads For example, *Rhodomonas lens* contains a red pigment resembling C-phycoerythrin, whereas another strain of *H virescens* yields a phycocyanin with only two absorption peaks

The possession of phycobilin pigments by members of the Cryptophyceae suggests a phylogenetic relationship among the cyanophytes, rhodophytes and cryptomonads, all of which possess these pigments It is possible that the ability to form large quantities of phycobilins arose more than once in evolutionary history, since by present evidence phycobilins are by-products of the biosynthetic pathway leading to the chlorophylls[10] However, in the absence of any evidence for a polyphyletic origin of these pigments, an attractive hypothesis is that the cryptomonads are the most archaic group of metaprotists, the survivors of the first organisms to make the transition from the mesoprotistan (red algal) level to the metaprotistan (flagellate) level, that is, from eukaryous organisms without vibratile organelles to those possessing pecilokonts ('true flagella') (Cf earlier papers[11] for discussion of these distinctions among the Protista)

We wish to thank the National Science Foundation of the United States for support, and Prof M Calvin and Dr O Holm-Hansen for the use of the Cary recording spectrophotometer

Phycoerythrins and Phycocyanins of Cryptomonads

By Dr C Ó hEOCHA and M RAFTERY

Chemistry Department, University College, Galway, Ireland

The algal biliproteins, phycoerythrins and phycocyanins are found in the Rhodophyta and Cyanophyta[1] Mrs B T Hepper (personal communication, 1954) noted the similarity between the absorption spectrum of an aqueous extract of the marine cryptomonad *Hemiselmis rufescens* Parke[2] and that of C-phycoerythrin, characteristic of the Cyanophyta At her suggestion, we have examined this pigment in greater detail and extended the study to a number of other marine cryptomonads kindly provided by Dr Mary Parke, of the Marine Biological Association Laboratory, Plymouth

Wolken and Haxo in a personal communication to Provasoli[3] noted that the red pigment of the cryptomonad *Rhodomonas lens* Pascher and Ruttner had similar light-absorption characteristics to phycoerythrin

All the properties of the water-soluble pigments which we have studied indicate that they may be classified as phycoerythrins and phycocyanins Four of the six species examined contained phycoerythrin only, one appeared to contain a small amount of phycocyanin in addition to phycoerythrin and one gave phycocyanin only The latter differed in absorption spectrum from any phycocyanin previously reported

The cryptomonads were grown in 'Erd Schreiber' medium[4] in either 250-c c Erlenmeyer or 1-litre conical culture flasks in weak white fluorescent light at room temperature

The algae were harvested by centrifugation of the cultures at about 10,000 r p m and extracted with distilled water in the cold after grinding with pulverized glass The extracts were centrifuged and clarified by passage through 'Supercel' filter aid When sufficient material was available the biliproteins were purified by adsorption chromatography on tricalcium phosphate–'Supercel'[5,6]

The pigments were washed off the columns with phosphate buffer (c 0 025 M), pH 6 4, to which saline had been added to promote desorption The yield after chromatography was spectrophotometrically estimated at 40–60 per cent , the cryptomonad pigments are less stable than R-phycoerythrin, which gave about 75 per cent yield[6] The phycoerythrin of *H rufescens* was also purified by chromatography on 'Amberlite *IRC*-50' resin and eluted with phosphate buffer (0 6–1 0 M , pH 7 2)

The phycobilin chromophores of the biliproteins were prepared by concentrated hydrochloric acid hydrolysis for 20–30 min at room temperature[7]

Absorption spectra were determined with a 'Unicam' S P 500 spectrophotometer

Table 1 gives the absorption maxima of the total aqueous extracts, the chromatographically homogeneous phycoerythrins and phycocyanins, and their phycobilin chromophores The spectral and chromatographic evidence indicates that, with one exception, each of the algae examined contains only one biliprotein That *Sennia* sp contains a small amount of phycocyanin, in addition to phycoerythrin, is indicated by the slight peak at 620–630 mμ, sufficient material was not available for chromatographic analysis

Table 1 SPECTRAL CHARACTERISTICS OF CRYPTOMONAD BILIPROTEINS

Alga and Plymouth reference	Absorption maxima in the visible spectrum (mμ)		
	Total aqueous extract	Chromatographically homogeneous pigment (in buffer, *p*H 6 4)	Phycobilin (in acid chloroform)
Hemiselmis rufescens ("D")	555	556	576
Cryptomonas sp (No 23)	550	545	576
Rhodomonas sp (No 29)	550	545	576
Cryptochrysis sp (No 14)	555	554	—
Sennia sp (No 9)	545 620–630	—	—
Hemiselmis virescens (?) (No 157)	588 615	588 615	—

Phycoerythrin The visible absorption spectrum of chromatographically purified phycoerythrin from *Hemiselmis rufescens* (Fig 1) does not differ appreciably from that of the total extract The absorption curves of the orange-fluorescing phycoerythrins from other species were similar in shape but the maxima lay at somewhat different wave-lengths (545 and 554 mμ) However, the same phycobilin chromophore appears to be present in all the cryptomonad phycoerythrins hydrolysed (Fig 1, Table 1), both the free phycobilin and its zinc-complex have the same spectral properties as those obtained from R-, C- and B-phycoerythrins[7], with the exception of the 640 mμ peak of the zinc-complex, which may be due to an artefact

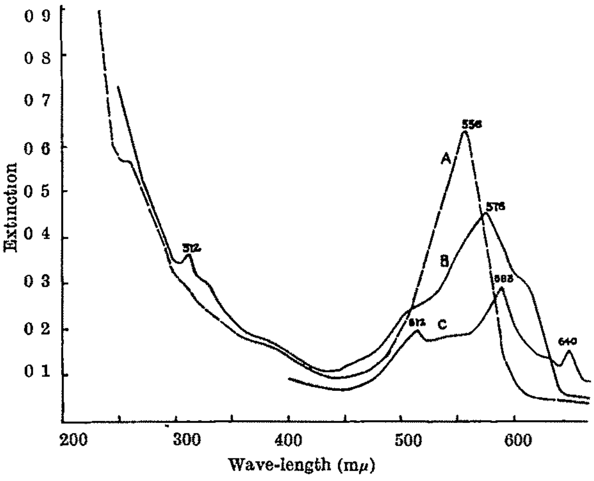

Fig 1 Absorption spectra *A* Phycoerythrin from *Hemiselmis rufescens* (in 0 025 *M* phosphate buffer, *p*H 6 4) *B* Phycobilin chromophore of *A* (in acid chloroform) *C* Zinc-complex of *B* (in chloroform)

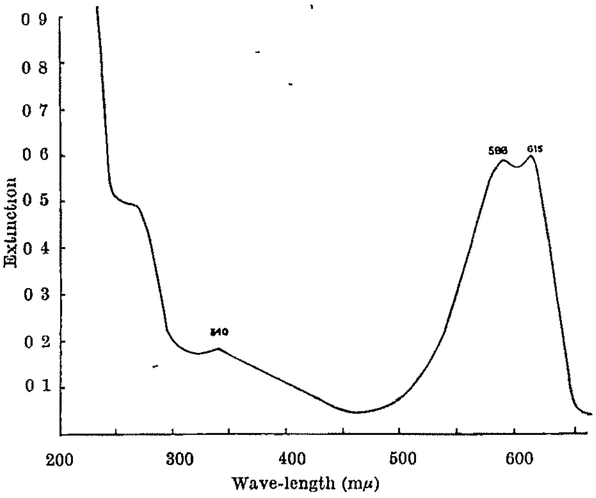

Fig 2 Absorption spectrum of phycocyanin from *Hemiselmis virescens* (0 025 *M* phosphate buffer, *p*H 6 4)

Higher concentrations of ammonium sulphate were required to precipitate the cryptomonad phycoerythrins than those of the other algal divisions, but their electrophoretic mobility was similar to that of R-phycoerythrin in acidic buffers However, at alkaline *p*H values *H rufescens* phycoerythrin moved toward the cathode on paper electrophoresis

Phycocyanin The absorption maxima of the blue-coloured red-fluorescing pigment of *Hemiselmis virescens* were at 588 and 615 mμ (Fig 2) The pigment appeared to be homogeneous, as fractionation could not be achieved by chromatography, paper electrophoresis, or ammonium sulphate precipitation The pigment was quite resistant to concentrated hydrochloric acid hydrolysis, but preliminary results point to the chromophore being a phycobilin

The results presented in this communication are essentially similar to those of Allen *et al* and of Haxo and Fork[8] They all point to the cryptomonad pigments being biliproteins related to those of the red and blue-green algae

The light absorption characteristics of the phycoerythrins present in five of the species examined resemble most closely those of C-phycoerythrin, the single absorption maximum of which can vary in position from 546 mμ (ref 9) to 552 mμ (ref 10) to 560, 563 and 565 mμ[6,7,11] The phycobilins are spectrally similar, but more detailed studies will be necessary before the exact structural relationships between the cyanophytan and cryptomonad phycoerythrins can be elucidated

The phycocyanins reported in the literature may be broadly classified as follows (approximate absorption maxima in brackets) R-phycocyanin (555 and 615 mμ), C-phycocyanin (615 mμ), allophycocyanin (650 mμ) The phycocyanin of the Plymouth strain of *Hemiselmis virescens* Droop (588, 615 mμ) differs from all these It also differs from that reported by Allen *et al*[8] for phycocyanin from the type strain (Millport No 64) of this alga (maxima at 580, 620–625, 645 mμ) The only other observed difference between these two strains is that the latter produces more carotenoid masses than the Plymouth strain (Mary Parke, private communication)

The cryptomonads (Cryptophyceae) have been generally placed in the algal division Pyrrophyta, which also includes dinoflagellates (Dinophyceae), the most characteristic pigment of which is the xanthophyll, peridinin[12]. In view of the present and related findings[8], the use of similarity in colour of cryptomonads and dinoflagellates as an argument for grouping them together, already suspect[13], would seem unjustified

We wish to acknowledge our sincere thanks to Dr Mary Parke, Plymouth, who provided the cryptomonad cultures and directions for their growth , and to the Chemical Society for a grant from the Society's Research Fund

Added in proof Careful chromatographic examination of extracts of all our phycoerythrin-containing cryptomonads has revealed the presence of small amounts of phycocyanin (λ_{max} c 635 mμ), when the algae were grown in a north window

Dr Michael Droop has kindly supplied us with a sample of the type-strain of *Hemiselmis virescens*, which we have grown under our culture conditions We have confirmed the findings of Allen *et al* [8] concerning the spectral properties of phycocyanin from this strain

Photosynthetically Active Accessory Pigments of Cryptomonads

By Dr F T HAXO and D. C FORK

Division of Marine Biology, Scripps Institution of Oceanography, University of California, La Jolla

THE Cryptophyceae have attracted interest as a minor algal group of uncertain taxonomic affinities, notable for the varied coloration of its pigmented representatives[1] The isolation into laboratory culture of the red, marine cryptomonad *Rhodomonas lens* by L Provasoli[2] has prompted studies of the nature and function of its plastid pigments The results are communicated here in brief, together with those obtained afterwards with the brown-coloured flagellate, *Cryptomonas ovata* These and the chemical investigations by Allen, McLaughlin and Dougherty and by Ó hEocha and Raftery[3] on a greater variety of species, establish the common occurrence of phycobilin-like pigments within the cryptomonads and their role as accessory photosynthetic pigments

Cultures of *Rhodomonas lens* Pascher and Ruttner and *Cryptomonas ovata* var *palustris* Pringsh were provided by L Provasoli and Richard Starr, respectively Both organisms yielded dense cultures after 4–6 weeks when grown in synthetic liquid media (unpublished formulations of L Provasoli) at 20° C with continuous illumination of 50–100 ft -candles intensity The cells were harvested by continuous-flow centrifugation at 5,000 r p m

Extraction and purification of the water-soluble pigments were carried out in the cold at *p*H 6–7 The cells were ruptured by passage through a needle valve (French press) at 15,000 lb /sq in , and the homogenate was clarified by centrifugation at 144,000*g* for 1 hr or more The pigment of the brilliantly fluorescing supernatant was precipitated with ammonium sulphate, re-dissolved in dilute saline, and chromatographed on tricalcium phosphate, using the method of Swingle and Tiselius[4] and Haxo, Ó hEocha and Norris[5], but omitting diatomaceous earth, which adsorbed a portion of the pigment irreversibly The fat-soluble pigments residing in the particulate fraction were extracted with methanol at *p*H 8–9 and fractionated by column chromatography on polyethylene powder and conventional adsorbents. Spectral analyses were made with a Beckman *DU* spectrophotometer.

Photosynthetic action spectra of freshly harvested cells were measured polarographically at 20° C using Haxo and Blinks's method[6] The reaction vessel was modified, however, by recessing the platinum electrode to accommodate a 0 25-mm layer of suspended cells, horizontally oriented in the beam from the monochromator

The spectral similarity of centrifuged aqueous extracts of *R lens* to C-phycoerythrin was noted earlier by Wolken and Haxo (cf L Provasoli, ref 2). On chromatographic columns several diffusely adsorbed pink zones were observed, all of which gave similar spectra The principal fraction, eluted with 0 1 *M* phosphate buffer, had the following characteristics maximal absorption at 545 mμ and secondary peaks at 390 and 275 mμ , strong yellow fluorescence , non-dialysable ; precipitation from aqueous extracts upon heating, by addition of three volumes of acetone, and by saturated ammonium sulphate at 0° C , photolability moderate at 20° C , slight at 5° C

Chromatographically purified pigment from *C. ovata* showed similar solubility properties, but displayed a reddish-orange fluorescence and absorption peaks at 568 and 285 mμ The pigments of the two cryptomonads are therefore spectrally distinct. Their observed properties suggest that they are bilichromoproteins similar to, but not identical with, the single-peaked C- and B-phycoerythrins[7,8] Their spectral properties and possibly also their precipitation only at high ammonium sulphate concentrations are features which distinguish them from the known bilichromoproteins of red and blue-green algae.

Both cryptomonads yielded three chlorophyll fractions (absorption maxima in ether) chlorophyll *a* (*665*, 615, 577, 530, *430*, *410* mμ) , chlorophyll *c* (*633*, 581, *450* mμ) ; and an unidentified hypophasic component (*667 5*, 615, 576, 531, 500, 429, *412* mμ). The latter may be a degradation product of chlorophyll *a*, but it was not observed in similarly treated extracts of a dinoflagellate (*Gonyaulax polyedra*) or of brown algae (*Eisenia arborea* and *Macrocystis pyrifera*) The solubility and adsorption properties, and in particular the spectral properties (Fig 1) of the chlorophyll *c* from *R lens* and *C. ovata*, corresponded closely with our preparations of this pigment from the above-named reference sources Evidence for the presence of chlorophyll *c* in *C ovata* was recently obtained by French, Elliott and Allen (ref 9 and personal communication) from absorption spectra of intact cells

The carotenoid hydrocarbons of *C. ovata* included, as the major component, α-carotene (identity confirmed by co-chromatography with an authentic

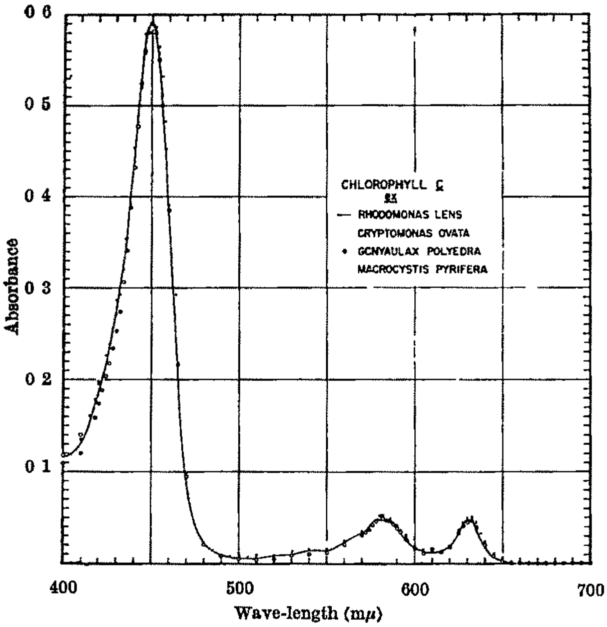

Fig 1 Absorption spectra in ethyl ether of chlorophyll *c* from *Rhodomonas lens*, *Cryptomonas ovata*, *Gonyaulax polyedra* and *Macrocystis pyrifera*

sample) and a less strongly adsorbed polyene (absorption maxima in hexane at 471, 442 and 418 mμ), probably ε-carotene The xanthophylls of *C ovata* were more abundant than the carotenes (ratio 2 4 · 1) The absorption spectrum and the partition behaviour of the principal xanthophyll corresponded closely to those of zeaxanthin, however, identity with the very similar pigment diatoxanthin was not precluded The poly-oxy carotenoids, peridinin and fucoxanthin, were not present in detectable amounts in extracts from either cryptomonad, although these pigments were readily isolated by the same procedures from reference sources

That the 'phycoerythrins' of both flagellates are effective sensitizers in photosynthesis is demonstrated by the photosynthetic action spectra and corresponding absorption spectra presented in Figs 2 and 3 Photosynthetic activity is highest in the middle of the spectrum (540–570 mμ) where the water-soluble pigments contribute most prominently to cell absorption A somewhat lower effectiveness for light absorbed by chlorophyll is indicated This situation is seen most clearly at wave-lengths beyond 660 mμ, where absorption may be attributed solely to chlorophyll

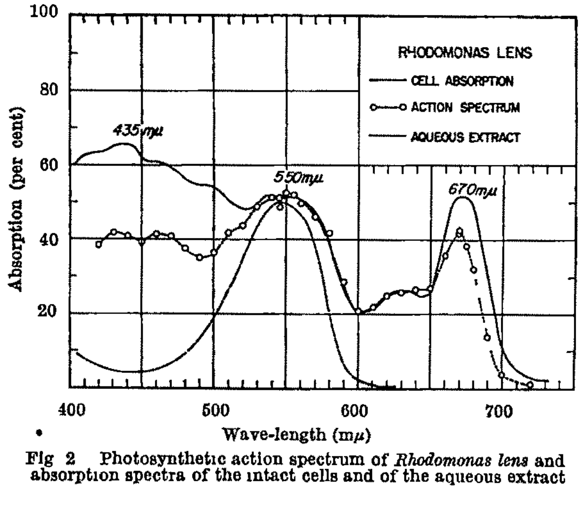

Fig 2 Photosynthetic action spectrum of *Rhodomonas lens* and absorption spectra of the intact cells and of the aqueous extract

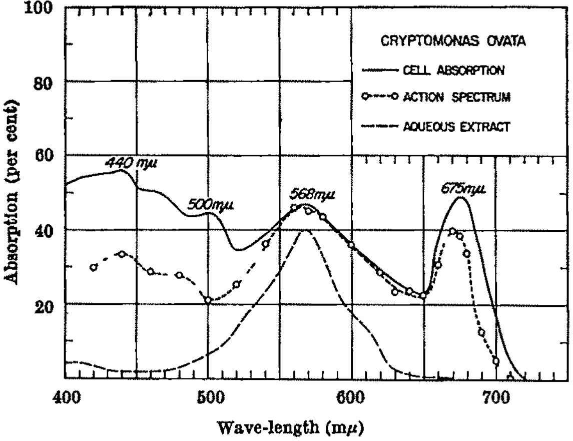

Fig 3 Photosynthetic action spectrum of *Cryptomonas ovata* and absorption spectra of the intact cells and of the aqueous extract

Previous work on the bilichromoproteins has been concerned mainly with those of red and blue-green algae, in which they function as accessory pigments to chlorophyll *a* alone[10] In the former group of algae, small amounts of chlorophyll *d* may also be present The cryptomonads now examined differ from other types of algae bearing phycobilin in that photosynthetically active bilichromoproteins are associated with chlorophyll *c* as well as chlorophyll *a* It is noteworthy in this connexion that the 'inactive chlorophyll' fraction of cryptomonads is small relative to that characteristically encountered in the Rhodophyta[6]

The evolutionary relationships of the cryptomonads remain unsettled, although Pascher[11] proposed that they are related to the dinoflagellates In this connexion, it is of interest to compare the plastid pigments of the cryptomonads and the dinoflagellates Both groups contain chlorophylls *a* and *c*, but these two chlorophylls also occur in diatoms and in the brown algae Peridinin, the characteristic carotenoid of dinoflagellates, was not detected in the cryptomonads that we have examined In further contrast, bilichromoproteins have not been detected in the dinoflagellates, although species with blue chromatophores[12] have not been examined in this respect. Available information, although limited, suggests that the cryptomonads possess a distinctive cor plement of plastic pigments

We are indebted to Nao Belser and William McCl for their assistance in certain phases of this study

FORTHCOMING EVENTS

*(Meeting marked with an asterisk * is open to the public)*

Monday, November 23

Royal Geographical Society (at 1 Kensington Gore, London, S W 7), at 5 p m —Mr Barrie E Juniper "Oxford University Tanganyika Expedition"

Institution of Mechanical Engineers, Education Group (at 1 Birdcage Walk, Westminster, London, S W.1), at 6 p m —Discussion on "Vibration Theory, Linear Systems and the subject 'Theory of Machines'"

Tuesday, November 24

Society for Analytical Chemistry, Physical Methods Group (at the Chemical Society, Burlington House, Piccadilly, London, W 1), at 6 30 p m —Mr R A C Isbell "The Design of Optical Instruments for Chemical Analysis"

Royal Aeronautical Society (at 4 Hamilton Place, London, W 1), at 7 p m —Prof D B Spalding "Heat and Mass Transfer in Aeronautical Engineering"

Society of Instrument Technology (at Manson House, 26 Portland Place, London, W 1), at 7 p m —Mr N I Walker "Application of Instrumentation to Glass Melting Furnaces"

Radar and Electronics Association (at the Royal Society of Arts, John Adam Street, Adelphi, London, W C 2), at 7 30 p m —Prof H E M Barlow "Waveguides for Long Distance Communications" *

Wednesday, November 25

Royal Society of Arts (at John Adam Street, Adelphi, London, W C 2), at 2 30 p m —Sir Christopher Hinton, K B E , F R S , and Sir William Holfrod "Power Production and Transmission in the Countryside—Preserving Amenities"

Geological Society of London (at Burlington House, Piccadilly, London, W 1), at 5 p m —Mr L R Raymond "The Pre-Permian Floor beneath Billingham, Co Durham", Dr J.M Hancock "The Cretaceous System in Northern Ireland"

Institution of Electrical Engineers, Electronics and Communication Section (at Savoy Place, London, W C 2), at 5 30 p m —Dr R L Smith-Rose "Radio Aspects of the International Geophysical Year"

Institute of Physics (at 47 Belgrave Square, London, S W 1), at 6 p m —Mr J F Coales "Education for Automation"

Institution of Mechanical Engineers (at 1 Birdcage Walk, Westminster, London, S W 1), at 6 p m —Prof A H Cottrell, F R S "The Effect of Nuclear Radiation on Engineering Materials" (Thomas Hawksley Lecture)

Society of Chemical Industry, Food Group (at 14 Belgrave Square, London, S W 1), at 6 15 p m —Mr G E Moss "Fortuitous Corrosion Inhibitor in Biscuit Mixes", Mr P G Seary "Recent Developments in Produce Pre-packaging"

Society for Analytical Chemistry (joint meeting with the Pharmaceutical Society of Great Britain, at 17 Bloomsbury Square, London, W C 1), at 7 30 p m —Meeting on "Methods of Assays of Capsicum, Lonchocarpus and Rauwolfia"

Thursday, November 26

Institute of Marine Engineers (joint meeting with the Society of Naval Architects and Marine Engineers, at the Memorial Building, 76 Mark Lane, London, E C 3), at 3 p m —Mr C C Pounder "Human Problems in Marine Engineering", at 5 30 p m —Mr J J Zrodowski and Mr H C Andersen "Co-ordinated Alignment of Line Shaft, Propulsion Gear and Turbines"

Institution of Electrical Engineers (at Savoy Place, London, W C 2), at 5 30 p m —Mr T R Manley, Mr K Rothwell and Mr W Gray "The Application of Low-Pressure Resins to some High-Voltage Switchgear Designs"

Institution of Mechanical Engineers, Applied Mechanics Group (at 1 Birdcage Walk, Westminster, London, S W 1), at 6 p m —Discussion on "The Application of Creep Results to Engineering Design"

Royal Aeronautical Society (at Church House, Westminster, London, S W 1), at 6 p m —Prof H Schlichting "Some Developments in Boundary Layer Research in the Last Thirty Years" (Third Lanchester Memorial Lecture)

Thursday, November 26—Friday, November 27

Institute of Petroleum (joint meeting with the Corrosion Group and the Chemical Engineering Group of the Society of Chemical Industry, in the Grand Council Chamber, The Federation of British Industries, 21 Tothill Street, London, S W 1), at 9 30 a m daily—Joint Symposium on "Corrosion Problems of the Petroleum Industry"

Friday, November 27

Royal Aeronautical Society (at 4 Hamilton Place, London, W 1), at 7 p m —Dr D R Walkie "Man and an Aero Engine"

Royal Institution (at 21 Albemarle Street, London, W 1), at 9 p m —Dr P T Haskell "Research in the War against Locusts"

Friday, November 27—Saturday, November 28

Botanical Society of the British Isles (at the Lecture Hall, The British Academy, Burlington House, Piccadilly, London, W 1)—Darwinian Centenary Conference

British Society for Immunology (at the Wellcome Foundation, 183 Euston Road, London, N W 1)—Symposium on "Persistence of Immunity" Chairman Dr C H Andrewes

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

James Morrison Research Fellow (not necessarily medically qualified), to pursue full-time research into the treatment of malignant disease by radiotherapy or other methods, at or in association with the David Morrison Research Department of the Sheffield National Centre for Radiotherapy—The Registrar, The University, Sheffield (November 21)

Research Fellow (physics graduate), to investigate the radiation from gas discharges—The Registrar, The University, Sheffield 10 (November 21)

Research Fellow (post-doctoral chemist or biochemist, with suitable interest and experience) in the Department of Chemistry of the Faculty of Science, to work on the synthesis of nucleotide analogues and the study of their metabolism—The Registrar, The University, Manchester 13 (November 21)

Plant Taxonomist (honours graduate majoring in botany, or equivalent qualifications, with some research experience in taxonomy, preferably in tropical plants) in the Division of Land Research and Regional Survey, Commonwealth Scientific and Industrial Research Organization, Canberra, Australia, to undertake taxonomic research essentially with New Guinea flora, by way of revision of selected group, in collaboration with an ecologist and forest botanist, in the identification of important species—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W C 2, quoting Appointment No 570/76 (November 27)

Fellow (honours graduate in science or engineering with postgraduate research experience involving microwave techniques in the field of paramagnetic resonance, particularly as applied to masers) in Radio Astronomy in the Division of Radio Physics, Commonwealth Scientific and Industrial Research Organization, Canberra, Australia—Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W C 2, quoting Appointment No 780/216 (November 28)

Chair of Chemical Engineering—The Registrar, University College, Singleton Park, Swansea (November 30)

Lecturer in Mathematics at Palmerston North University College (Victoria University of Wellington), New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (November 30)

Lecturer or Senior Lecturer in Preventive Medicine at the University of New England, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (November 30)

Lecturer in Civil Engineering—The Registrar, University of Adelaide, Adelaide, South Australia (December 7)

Senior Research Fellow in the Institute of Education—The Registrar, The University, Leeds 2 (December 7)

Assistant or Associate Professor of Applied Mathematics—The Chairman, Department of Mathematics, McMaster University, Hamilton, Ontario, Canada (December 10)

Senior Tutor/Lecturer in Psychology at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (December 11)

Lecturer in Geology and/or Geophysics at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (December 12)

Chair of Philosophy—The Registrar, The University, Leeds 2 (December 31)

Professor of Applied Mathematics—The Secretary and Registrar, University College of North Wales, Bangor (January 1)

Director of the Institute of Education and Professor of Education—The Registrar, The University, Leeds 2 (January 15)

Biologist (with a good honours degree in zoology and/or botany, preferably a knowledge of both subjects and some postgraduate experience) with the Fauna Research Unit, Kenya, to carry out research on Kenya fauna to provide data for the building up of life-tables, details of feeding habits, enemies, predators and diseases—The Director of Recruitment, Colonial Office, London, S W 1, quoting BCD 61/7/09/T

Biologist (with a university degree in science, including botany and zoology, with preferably a diploma in education and/or teaching experience) in the Department of Agriculture, Uganda, to teach scientific subjects in an agricultural course of the standard of the Diploma course of an agricultural college in the United Kingdom—The Director of Recruitment, Colonial Office, London, S W 1, quoting BCD 63/9/030/T

Botanist (Plant Pathologist) (with a good honours degree in botany or agricultural botany, and at least two years postgraduate experience in plant pathology) in the Department of Agriculture, Uganda, to diagnose the causes of crop diseases and to recommend control measures, and to assist with the breeding of disease-resisting crops—The Director of Recruitment, Colonial Office, London, S W 1, quoting BCD 63/9/02/T

Chemists, Senior Scientific Officer or Scientific Officer grade in Research and Development Establishments of the Ministry of Aviation, mainly Southern England, offering a wide range of problems including high polymers, safety glass and ceramics, electro-chemistry, propellants based on polymeric fuels, combustion reactions, reaction kinetics, chemical engineering, initiation and detonation of high explosives, corrosion, and analytical methods—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S W 1, quoting Ref F 647/9A/AA

ENTOMOLOGIST (Scientific or Senior Scientific Officer grade, with a good honours degree in zoology, with postgraduate training or experience in entomology) at the West African Cocoa Research Institute, Ghana, for research on insect pests of cocoa—The Director of Recruitment, Colonial Office, London, S W 1, quoting BCD 197/200/02/T

PRINCIPAL OF THE ROYAL TECHNICAL COLLEGE OF EAST AFRICA, Nairobi, and **PRINCIPAL-DESIGNATE** of the proposed University College into which the Royal Technical College is to be transformed—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1

SENIOR AGRONOMIST (with a degree in agriculture or in natural science with a postgraduate diploma in agriculture and considerable experience in field experimentation, preferably with perennial tree crops) at the West African Cocoa Research Institute, Ghana, to take charge of the Agronomy Section and co-operate with senior specialist officers in the field experimental work of the Institute—The Director of Recruitment, Colonial Office, London, S W 1, quoting BCD 197/200/010/T

SOIL CHEMIST (with an honours degree in chemistry or in natural science including chemistry, and at least two years postgraduate training or experience as a soil chemist) at the West African Institute for Oil Palm Research, Nigeria, for the study and analysis of soil types with a view to improving soil conditions—The Director of Recruitment, Colonial Office, London, S W 1, quoting BCD 197/199/016/T

THE DEVELOPMENT OF PUBLIC SERVICES IN A MODERN DEMOCRACY

TWO of the most valuable chapters in Dr Brian Chapman's recent book, "The Profession of Government" (London George Allen and Unwin, Ltd , 1959 28s net), are those in which he discusses the public service trade unions, and the relations between public officials and the public The two subjects are closely connected, and in the compass of little more than a score of pages Dr Chapman focuses attention on some problems of vital importance to the functioning of a democracy, of which there is little evidence that administrators, professional associations or the public generally are aware Nevertheless, upon the effective solution of such problems the wise use of scientific and technical resources and the very possibility of creative leadership, in the service of the State or elsewhere, may largely depend

Dr Chapman goes unerringly to the root of the problem with public service trade unions All the evidence points to the truth that people employed in government service tend to become not only self-governing but also self-employed Moreover, the strength of these unions is in the lower ranks, and while in these grades parity with outside employment has been maintained, financially there is a genuine conflict of interest between the various grades of the public service Unions representing the lower- and middle-grade officials will not accept a policy of discriminatory rises for particular grades, and for this financial reason alone, the higher public officials insist on special representation

Now, while the European public services have acquired most of the characteristics of a profession, even for the higher Civil Service in Britain there is no recognized professional qualification or any general acceptance that the profession should have a monopoly of government The acquisition of a recognized public status and the growth of professional training schemes in the Civil Service only partly compensate for this lack of a professional qualification Furthermore, the professional ways of thought of public officials, more especially the senior officials, are distinctive, imposed on them by the nature of their duties , and while generally such officials are naturally affected by the way the public regard them and, in consequence, by the underlying philosophy of society and the State reflected in a country's view of public administration, Dr Chapman's comparative survey points to a surprising similarity in attitudes in senior public officials in all European public services

Dr Chapman emphasizes the dependence of these attitudes on the nature of the official's duties and not on his social class In all the countries covered by him, the public official is in social terms a typical member of the middle class , but there are few reliable statistics on the social origins of public officials in Western Europe and it is not possible to prove that public service is a factor in social mobility It is certain, however, that social class in the public service does not work in reverse The sons of members of the administrative class are practically never found lower down the scale , unless they can join at their father's level, they enter another profession It is also clear that the working class and the agricultural population are both under-represented at all levels of the administration in comparison with their proportion in the population

Nevertheless, Dr Chapman's survey suggests that this question of social origin is relatively trivial, in comparison with the decisive influence of professional duties on their attitudes Indeed, social class and their duty to society, as well as the nature of their work, alike make senior officials conservative, and their first preference is to keep the peace and maintain the *status quo* In spite of this, they sympathize with efforts to remove the worst or most noticeable abuses in the fields of government which are their direct concern Dr Chapman points out that they, frequently more so than politicians, are aware of the black spots of society, even though their knowledge may be second-hand, and that this instinct for improvement has been responsible for many minor social and industrial reforms throughout Europe, particularly in the newer fields of government Most frequently, however, the instinct to improve is confined to the official's special field

It is inherent in this that senior officials should incline to believe that they are more disinterested, intelligent and far-sighted than other people engaged in government, and this is due not so much to authoritarianism as to the distrust of the professional for the enthusiastic amateur Again, awareness of public responsibility and of the impossibility of full impartiality and equality of treatment can also lead to a clash between professional and amateur, and to divergence between official and public The official is aware that he has to deal with a world that is neither efficient, rational nor equitable, and distrusts the claim that the public has an inalienable right to efficiency, impartiality and rationality He is also better aware than the public of inconsistencies which may mar their mutual relations

All this bears profoundly on the two questions which Sir George Schuster discusses in his review of the working of the National Hospital Service in Britain, entitled "Creative Leadership in a State Service"* Can a State-directed service be an instrument of dynamic progress and provide scope for individual enterprise and initiative ? Can State-directed 'welfare' measures produce true welfare—that is, welfare judged according to a standard of values appropriate to a modern society ? These questions, however, may be considered in the light of three major points which Dr Chapman makes as the outcome of his review of Western Europe as a whole.

---

* Creative Leadership in a State Service a General Survey (Hospitals and the State Hospital Organization and Administration under the National Health Service, Sixth and final Research Paper) Pp iii+80 (London Acton Society Trust, 1959) 4s

First, in every country the increase in public services has not been accompanied by sufficient serious thought as to the best way of absorbing them into the structure of the modern State The haphazard creation of semi-public, public, quasi-private and partly autonomous bodies complicates law, operation and control Secondly, clarification in this field might help to disentangle some of the more acute problems of public service law There is no sensible reason, Dr Chapman suggests, why a postman should be a Civil servant and a gas inspector or railway driver should not Nor is there any serious reason why the vast mass of manipulative, clerical or even executive staff employed in public administration, whose duties are exactly comparable with those in private employment, should not be engaged on private law contracts A much more vigorous distinction in public administration between public officials and private law employees would both simplify public service law and permit an element of flexibility in personnel matters which is lacking in many countries, and also allow the general unification of the public services to be considered seriously This is particularly important at the higher levels, where it should promote a proper balance between administrators, managers and technologists, and remove some of the anomalies which disturb the Institution of Professional Civil Servants It might well be reconsidered whether the chemist, the physicist, the engineer, for example, engaged on professional duties in the Government service, need necessarily be a Civil servant unless those duties include public administration

Thirdly, Dr Chapman remarks that the recent awareness of the need for better government public relations has gone no further than communicating to the public what the public service concerned is doing, rather than why it is doing it This is an essential to informed public discussion, but in his reasoned attack on the secretiveness of British Government methods, Dr Chapman is too concerned with the negative effects of secrecy to emphasize the positive contribution of informed discussion to the functioning of democracy In Western democratic theory, government is the task of representatives of the electorate, and no growth in the complexity of the tasks of government can make government the task of a profession , it can only emphasize the responsibility of the professional administrator for seeing that the implications and consequences of particular decisions and policies are clearly understood by the elected representatives

The relevance of Dr Chapman's observations and suggestions to the problem of creative leadership which Sir George Schuster discusses in the context of the National Health Service in Britain is apparent from the start of Sir George's analysis That analysis follows on a general survey of hospital organization and administration under the National Health Service made by the Acton Society Trust, which vindicated the Government's original purpose to allow the fullest possible decentralization of the Hospital Service While this should be maintained, the Acton Society Trust points out that the Ministry is still left with a responsibility it cannot abdicate—that of giving inspiring leadership and guidance, interpreting the lessons of decentralized experience, and involving national resources for dealing with the problems that can only be effectively handled on a national basis In particular, the Trust's survey led to the conclusions that not enough had been done to study and interpret current experience , that a frequently changing junior political Minister is ill-placed to satisfy the need for continuous inspiring leadership in a great operating service , that the Ministry as at present organized does not provide a staff containing enough men with the right kind of knowledge based on practical experience in the field , that this staff is itself hampered by lack of an adequate statistical and intelligence service, and that the Ministry's advisory bodies cannot fill the gap

Sir George Schuster begins with Mill's prescription—the greatest dissemination of power consistent with efficiency but the greatest possible centralization of information and diffusion of it from the centre, and with Mill's dictum that a Government cannot have too much of the kind of activity which does not impede but aids and stimulates individual execution and development In emphasizing, however, the intensely human character of a health service and the large number of voluntary unpaid members concerned in its control, Sir George directs attention to two further questions which arise out of those to which he was asked to give special attention First, how—by what working methods and arrangements—can the preservation of the voluntary spirit of service which is embodied in the boards and committees of management be most effectively combined with adequate power for the Minister to discharge his responsibility to Parliament for ensuring efficiency and economy in the expenditure of public money ? Secondly, how can the professional freedom of medical practitioners and surgeons, on whose skill the work of the hospital service ultimately depends, be reconciled with the just claims of public authority ?

Obviously, these are essentially the questions that arise in regard to public expenditure on research and on the universities, and the answers Sir George Schuster suggests are of great interest to those concerned with the functioning of the University Grants Committee, public accountability in the nationalized industries and the deployment and balance of the national effort in scientific and industrial research and the control of expenditure in that field They are questions of far-reaching importance which should be a prime concern of the newly appointed Minister with special responsibility for scientific effort in Britain Moreover, while Sir George Schuster does not deal to any extent with the question of professional freedom, he has raised a general issue which demands the attention of professional bodies generally, and the importance of which in its broadest context has also been admirably stated by Sir Solly

Zuckerman in his recent address (see *Nature*, July 18, p 135) delivered at the California Institute of Technology

It is no disparagement of the importance of the National Health Service to suggest that Sir George Schuster's pamphlet is of even wider public interest in the context of the problem of government generally, the place and use of the expert in public affairs, the responsibilities of professional organizations and the functions and staffing of the Civil Service Like Dr Chapman, he displays issues where fresh thought is urgently required, practices which require critical and independent examination, and preconceived ideas and even traditions which should be challenged It is to be hoped that the place of his pamphlet in the survey of the National Health Service made by the Acton Society Trust will not lead other professional associations, or indeed the scientist and technologist generally, to miss the challenge to creative leadership which he offers to them no less than to the medical profession itself

BRITISH INDUSTRY

The Structure of British Industry

A Symposium Edited by Duncan Burn Vol 1 Pp xvii+403 45*s* net Vol 2 Pp xii+499 50*s* net (National Institute of Economic and Social Research) (Cambridge At the University Press, 1958)

FOR a long time the best general account of the main British industries in a single book has been Prof G C Allen's famous work, "British Industries and their Organisation", first published as long ago as 1933, though modernized in successive editions since The two volumes here under review constitute, therefore, the first new major attempt for a long time to provide something which, in principle, every British student of economics (and many overseas students) would like to have

As a new standard text-book and work of reference, this book has very great strength, but also, inevitably some weaknesses Its strength is that it calls upon an extremely able team of writers, many of them fresh from, or still engaged in, the task of writing larger monographs on the industries which they here discuss , the rest, who have made investigations for the sole purpose of their contributions to this symposium, remarkably well-selected and successful Its weakness is that it lacks the uniformity which can be achieved by a single author, asking roughly the same questions about a number of industries Apart from setting out the facts of size and number of firms, the different contributors adopt a variety of approaches which makes the editor's gallant effort to treat some matters of general interest in his final chapter a difficult one The student may also find the size and cost of this important work formidable

It would be wrong, however, to judge it merely as a text-book It is an important fact about economic studies that in the past decade or two, while at their theoretical end they have been accused of becoming more difficult for the practical man to understand, they have undeniably gained enormously in realism through economists consorting with practical men, either as Civil servants or as students of industrial problems in the field No one man can nowadays attain to comprehensive first-hand knowledge of a wide range of industries, as Alfred Marshall was able to seventy years ago—hence the necessity for a symposium—but the intimacy of the knowledge attained by the contributors, and the fundamental nature of the questions which some of them attempt to answer on such matters as pricing policy, are evidence of the increased penetration of economists generally into the realities of industrial life

A list of the industries dealt with shows the wide scope of these volumes agriculture, building, road and rail transport, coal, oil, chemicals, steel, building materials, machine tools, motors, aircraft, shipbuilding, electronics, cotton and rayon textiles, woollen and worsted, man-made fibres, pottery, pharmaceuticals, and cutlery It suggests, too, the variety of different 'atmospheres' to be dealt with, ranging from those dominated by State policy, as in the case of agriculture and aircraft production, to the predominantly private commercial atmosphere of, for example, the pottery industry , or from ferments of technological change, as in electronics or pharmaceuticals, to the static environment of wool textiles It need scarcely be said that the nature, possibility, and meaning of competition vary enormously from one industry to another The more closely one looks at most industries (even those which are in some sense the most 'competitive'), the further they appear to lie from the old model of 'perfect' competition between firms making exactly similar products The nearest simple model of wide application, indeed, would seem to be that of 'oligopolistic' competition, between firms which compete directly (or not quite directly) with a fairly small number of others—though with the important reservations that 'potential' competition, often from users of the product who might turn to manufacturing it themselves, is frequently just round the corner, and that the weapon of competition is increasingly often an improvement in design rather than a reduction in price. Nearly everywhere there is some evidence of increasing concentration, but in very many places the small firm is remarkably viable, not by any means always for the same reason Where concentration has gone so far as to create monopoly power, it becomes very evident that this power, though it may not be harmless, is subject to a variety of checks, quite apart from those imposed by legislation The case of coal, where absolute monopoly is itself the product of legislation, shows how powerful the restraint imposed by competition from quite different products can be

The question how far the structure of British industry conduces to high and increased efficiency is one which, again, admits of no simple answer The very general impression, indeed, is that the adjustments of the past twenty years have been made with reasonable smoothness and with gains of efficiency which are often striking This, however, should not lead the reader into complacency The contributors to this work have the relatively pleasant task of portraying British industry on the favourable wicket of expansion in the national economy and in world trade It is a very different story from the agonizing chronicle of difficult contraction in so many of the basic industries between the Wars It may be as well to reflect that, while we may hope never again to see general stagnation of the economy or a major depression in its total activity, we have given a number of hostages to fortune in, for example, motors and shipbuilding, which may find how much more difficult it is to be progressive in adversity than in prosperity

TURNING POINTS IN PHYSICS

Turning Points in Physics

A Series of Lectures given at Oxford University in Trinity Term 1958. By R. J. Blin-Stoyle, D. ter Haar, K. Mendelssohn, G. Temple, F. Waismann and D. H. Wilkinson. (Series in Physics.) Pp. v+192. (Amsterdam: North-Holland Publishing Company; New York: Interscience Publishers, Inc., 1959.) 20*s*.

DURING Trinity Term, 1958, a series of lectures was organized by the Reader in the Philosophy of Science and the Lecturer in the History of Science in the University of Oxford. The lectures, collected in this volume, are: (1) "The End of Mechanistic Philosophy and the Rise of Field Physics", by Dr. R. J. Blin-Stoyle; (2) "The Quantum Nature of Matter and Radiation", by Dr. D. ter Haar; (3) "Probability enters Physics", by Dr. K. Mendelssohn; (4) "From the Relative to the Absolute", by Prof. G. Temple; (5) "The Decline and Fall of Causality", by F. Waismann, and (6) "Towards New Concepts: Elementary Particles", by Prof. D. H. Wilkinson. The audience to whom they were originally addressed was composed of philosophers and scientists who were not physicists. The publishers suggest that they can be understood by laymen; I have the word of an historian colleague, who recommended the book with great enthusiasm for the general library, that this is so. He had some reservations, it is true, about grasping all the points raised; and it is not exactly light reading, even for the scientist. As an account of the origins and development of the present state of theoretical physics it is most stimulating; and to be able to communicate so much of the physicist's outlook at a non-specialist level is a magnificent achievement.

The title "Turning Points" is itself significant. Thirty or forty years ago classical physics was spoken of in rather dismal terms of 'downfall'; by inference, the supplanting modern physics was undergoing uplift—and it apparently did, quite out of this world. But the outcome of all this has not been depression or exaltation; nothing less than a complete re-orientation of all our ideas has been necessary, and this turning has not really been a sudden event. As the first lecture points out, the fulcrum was effectively set up by Faraday; and the statistical approach goes back nearly as far—but applied only to classical particles. The quotation from Niels Bohr—"My method is to try to say what I cannot say, because I do not understand it"; Dr. Waismann's statement that quantum physics presents a strong case against traditional logic; and Prof. Wilkinson's remark that the first stumbling block for people who want to understand the elementary particles is that some of the things they learn run counter to common sense, between them emphasize the kind of turning that is demanded. In the macroscopic world of everyday life, we can 'understand', use classical ideas, relate matters as 'cause and effect', work to the rules of logic, and be guided by common sense. In the microscopic world of atomic physics, none of these things can happen. The physicist has to live a life of double-dealing between two worlds—observing with macroscopic apparatus, and interpreting in terms of microscopic concepts which have no counterparts in ordinary life, either in essence or in behaviour. Each of the lectures shows clearly the terms of reference within which modern physics operates.

Rule out causality, mechanical particles, identifiable individual particles, and the appeal to analogy taken from everyday life, and what is left of the microscopic world except concepts that can only be handled as mathematical abstractions? This question, which is the real difficulty facing the ordinary reader (and most of us older physicists as well), is squarely met in the contributions of Prof. Wilkinson and Prof. Temple. The answer is, general invariance or symmetry or conservation conditions, and 'properties' (if that is the term) to which such conditions can apply—such as Newton's third law of motion (Temple) or the conservation of isotopic spin (Wilkinson), which seem indeed to have much in common.

Illustrations and examples strike a fresh and original note. The derivation of the Lorentz transformation (Temple) is neater and simpler than that in the text-books. The conflict between causality and the uncertainty principle (Waismann) is illustrated by idealized experiments, and numerous examples of the application of the principle are given. The account of the elementary particles (Wilkinson) is both up to date in content and superb in its clarity; the author does not, of course, lament that physicists are large compared with m_e, and long-lived by K-meson standards—but he mentions that this immense difference in scale prevents us from even being able to describe the microscopic world in ordinary language at all. The lighter touches and personal reminiscences that drop into place here and there suggest that the authors were thoroughly enjoying their task: they must have done, to be able to accomplish it so brilliantly. G. R. Noakes

CATALYTIC PROCESSES AND PETROLEUM

Catalysis

Edited by Prof. Paul H. Emmett. Vol. 6: Alkylation, Isomerization, Polymerization, Cracking and Hydroreforming. Pp. vi+706. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1958.) 156*s*. net.

THIS volume is the penultimate one in this very comprehensive series; it deals with the catalytic processes that have now such an important place in the petroleum industry. The editor is to be congratulated on this further stage of his monumental task and in particular on achieving a very reasonable uniformity of treatment in the six 'chapters' written by eleven authors. Each chapter forms a clearly defined section dealing with an important refinery operation involving catalysis and comprising alkylation (with 59 references), isomerization (322 references), polymerization of olefines (212 references), catalytic cracking (126 references) and reforming (164 references), together with a chapter on the mechanism of polymer formation and decomposition (374 references). The large number of references makes the volume a valuable starting point for further study, particularly to chemists entering the petroleum and petrochemicals field. At the same time the authors have accepted the responsibility of surveying this mass of literature and presenting it as a coherent account and not simply as a collection of abstracts.

Earlier volumes in this series dealt, of course, with the fundamentals of catalysis, so that the authors here are free to deal with the more specialized and practical aspects This still leaves a large field to be covered and in most cases the authors set clearly defined limits to the subjects they discuss

Alkylation is dealt with in a clear and concise manner, and the comment in this chapter that "the development of a body of knowledge in alkylation embraces in chronology the development of highly precise analytical distillation methods and spectroscopic identification methods for hydrocarbons" can apply to each chapter in turn It is interesting, though possibly fruitless, to speculate on the course of events if our modern techniques of hydrocarbon analysis had been available to the pioneers in this field

In the chapter on isomerization, a much more complete treatment is attempted under the headings "General Aspects and Mechanisms", "Kinetics" and "Equilibria" The treatment is very systematic and will be of particular value to research workers entering this field It is irritating, however, to find bracketed explanations such as "BF_3 (boron trifluoride)" and even "I_2 (iodine)" in a book of this type The chapter on mechanisms of polymer formation and decomposition follows, its scope being clearly defined and topics such as polycondensation, co-polymerization and hydrolytic and enzymatic cleavage reactions are included This is an excellent survey of the specified fields Polymerization of olefines is the subject of the next chapter, the presentation being limited to liquid polymers only, ranging up to lubricating oils and viscosity index improvers After an excellent discussion of the thermodynamics and mechanisms, commercial processes are dealt with in moderate detail The behaviour of pure hydrocarbons is the main theme of the chapter on catalytic cracking, the commercial processes being discussed only briefly This again is a necessary limitation in such a wide field A list of twelve phenomena is given, which it is suggested an acceptable theory of catalytic cracking should explain The poisoning action of nitrogen bases, a discussion of which immediately precedes the list, might well have been added to it The final chapter, on catalytic reforming, includes a good deal on the commercial processes and is again a valuable survey

The printing and diagrams are up to the high standard one expects, and the volume will certainly join the others of the series as an important contribution to the literature of chemical industry in the widest sense DAVID M WILSON

SEX ON THE FARM

Reproduction in Domestic Animals
Vol 1 Edited by H H Cole and P T Cupps Pp xv+651 (New York Academic Press, Inc, London· Academic Press, Inc (London), Ltd, 1959) 14 50 dollars

THIS book, when the second volume is published, will have to stand comparison with such well-known treatises as "Allen's Sex and Internal Secretions", a third edition of which is in preparation, "The Hormones", edited by Pincus and Thimann, and, above all, "Marshall's Physiology of Reproduction", publication of the third edition of which began in 1952 and is not yet complete

The present volume opens with two chapters on the anatomy of the male and female reproductive organs and is thereafter almost wholly concerned with the female There are four chapters, three of which are of a fundamental nature, dealing with the role of various hormones and of the nervous system in reproduction After five chapters describing the œstrous cycle of farm animals and the bitch (apparently the cat is not considered a domestic animal), fertilization, implantation, the physiology of the placenta and pregnancy, and parturition are covered in four chapters The volume ends with a chapter on lactation

In the space available it is impossible adequately to write a critical appreciation of so important a book, all that can be done, at the risk of appearing invidious, is to refer to those topics which particularly interest the reviewer He well remembers the absorbing interest with which he read in 1939 C G Hartman's outstanding chapter in "Sex and Internal Secretions" (second edition) Does the present volume contain a chapter comparable with this? This is scarcely to be expected since the power to write so vividly is unfortunately rare Perhaps C W Emmens's contribution on the role of the gonadal hormones in reproduction comes closest, for it is written in a flowing style and deals lucidly with a complicated subject Miriam E Simpson gives an authoritative and well-written account of the pituitary and other gonadotrophins, though her treatment of the subject might appear to be orientated towards man rather than farm animals C W Turner's chapter on the thyroid, adrenal cortex and posterior-pituitary hormones is something of a mixed bag, heavily over-shadowed by a discussion of practical applications of thyroid physiology in the domestic fowl and farm animals, a subject which might well have been assigned a chapter on its own The adrenal cortex and posterior-lobe hormones could easily have been expanded to separate chapters T J Robinson's contribution is noteworthy for an interesting and largely first-hand account of how the œstrous cycle of the ewe can be manipulated hormonally with the view of increasing fertility, it includes a short section on the 'doe' which, despite the "Shorter Oxford English Dictionary", turns out to be the female goat The brevity of this section reflects the paucity of experimental work on this species and it is the more surprising that a ten-year-old paper by the reviewer and his colleagues on out-of-season breeding was overlooked J Meites contributes a comprehensive review of mammary physiology with much of which the reviewer has little quarrel, though two points merit mention Even considering that the chapter must have been written nearly two years ago, it is surprising to learn that somatotrophin has no major role in mammary growth, and also to see cogent evidence for a role of oxytocin in the release of prolactin dismissed so summarily

A book of this nature must be considered as a whole rather than as a collection of isolated essays, and if it is to be successful, the editorial guiding hand must be all-pervading, if unobtrusive One criticism of the present book is that there is too little evidence of editorial co-ordination For example, posterior-pituitary hormones, principally oxytocin, are dealt with in several chapters but with little cross-referencing, the same applies to relaxin The value of the book to the reader would have been much enhanced had adequate cross-references been given in these and many other instances A number of other blemishes could have been eliminated by sterner editorial action There are infelicities such as the use of "beef" and "pork" to describe pituitary glands from the ox and pig (yet "mutton" is not used for sheep pituitaries, as it should have been for consistency), and the widespread use of the inept term "let-down" which the reviewer thought he had knocked out twelve years ago, but which has persistently refused to lie down There are some inconsistencies such as the use of "dog" rather than "bitch", while the females of the ox, horse, sheep and pig are called "cow", "mare", "ewe" and "sow" Bibliographical errors are also more frequent than they ought to be, particularly in Chapter 7 British readers are by now inured to what seems to be becoming standard American practice in the use of prepositions (two of the more startling examples being "identical to" and "different than"), but in a book of this calibre one would not expect to find a sentence like (p 163) · "A hypothyroid monkey put on a very low thyroid dosage for a period of ten days always resulted in the return of menstrual function"

The main justification for the publication of this book in face of the well-established and authoritative treatises mentioned at the beginning of this review must lie in its emphasis on farm animals and its relatively modest price, which will bring it within the reach of the private purchaser Is this publication justified ? On the showing of this first volume the reviewer thinks so, despite the criticisms mentioned above, and he is glad to recommend it

S J Folley

HÆMOGLOBIN AND SENSORY MECHANISMS

Progress in Biophysics and Biophysical Chemistry

Vol 9 Edited by Prof J A V Butler and Prof B Katz Pp vii+388 (London and New York Pergamon Press, 1959) 105*s* net

FOLLOWING the present reviewer's criticism in *Nature* of the previous volume of this series on the grounds that few of the articles matched up to the aims stated in the preface, the editors have prudently suppressed the customary preface in this volume Perhaps they need not have feared ; their aims may well be achieved, for five out of the seven articles are written in such a way as to be intelligible and interesting to non-specialists in their subjects Two of these articles have the special flavour that only comes when a scientist with a flair for exposition describes the development of a subject he has himself largely invented and contributed to These are F. J W Roughton on the kinetics of oxygen and carbon monoxide uptake by red cells and by solutions of hæmoglobin, and W A H Rushton on visual pigments and their measurement in the living human eye The book opens with an enthusiastic and highly interesting account by Q H Gibson of the rapid reactions of hæmoglobin with gases The last article which can be recommended without reservations as to style or scientific content is that in which J A B Gray describes what is known of the way sensory endings, sensitive to mechanical change, convert mechanical energy into streams of nervous impulses , he illustrates the argument mainly from his own and his collaborators' pioneer work on the Pacinian corpuscle

It would have been churlish to exclude the article by D A McDonald and M G Taylor on the hydrodynamics of the arterial circulation from the category 'intelligible and interesting', but after reading it I found I was not convinced either that their problem was an important one, or that they had advanced much towards a solution

The two remaining papers are by A Peterlin on molecular dimensions and light scattering (fifteen pages of references) and by C de Duve, J Berthet and H Beaufay on gradient centrifugation of cell particles Both of these appear to be competent and clear descriptions of the theory and practice of their highly specialized techniques, which would no doubt be of great convenience to anyone directly concerned But this volume is supposed to be about progress Is a technical description of the methods by which progress may have been achieved in the past and by which it is hoped to achieve it in the future any substitute for a critical account of progress ? It certainly makes very much duller reading than the real thing Fortunately, there is plenty of the real thing in this mainly excellent work

P A Merton

COLOUR REPRODUCTION

The Reproduction of Colour

By Dr R W G Hunt Pp 208+10 plates. (London Fountain Press, 1957) 63*s* net

THIS book expounds the principles and the crucial technical devices of the processes used in colour reproduction in photography, printing and television Many of these processes are now extremely intricate—for example, the action of the couplers of various kinds used in colour photography and the coding and transmitting of colour information on television wave-bands of limited width In the difficult task of explaining essentials in an easily read text with clear and simple diagrams and a minimum of mathematics, the author has been highly successful. A course of lectures (Royal Institution, 1953) was the starting point and much of the freshness and intimacy of a good lecture style has been preserved

A common element linking all the reproduction techniques is a dependence on the basic ideas of colorimetry and the perception of colour by the human eye, fields in which Dr Hunt's own researches are well known The exposition here is unexceptionable and, most important, it has not been allowed to expand unduly so as to upset the balance of the work Colour reproduction techniques, in their primitive form, are not capable—even theoretically—of giving exact reproduction, and much of what Dr Hunt has to say concerns colour correction methods the nine-page chapter on the general masking method in photography and the discussion of developments from Neugebauer's analysis of dot image reproduction in printing are particularly informative brief-accounts The difficulties of assessing the 'quality' of the final result in colour reproduction are well brought out, with emphasis on the inadequacy of a demand for a simple point-to-point correspondence with the original

Although the book appears to be addressed mainly to a rather lay circle, that is to say, people having to do with colour pictures in various ways but not experts, it is certain that many readers, knowledgeable in one area of the wide field covered, will find most useful this insight into related techniques In the quality of the coloured plate illustrations the publishers have not failed the author W S Stiles

Excursion Flora of the British Isles

By A. R. Clapham, T. G. Tutin and E. F. Warburg. Pp. xxxiii + 579. (Cambridge: At the University Press, 1959.) 22*s*. 6*d*. net.

THIS volume has been developed from Clapham, Tutin and Warburg's "Flora of the British Isles", published in 1952, by curtailing descriptions to little more than is needed for identification, by omitting all information not strictly relevant to identification, by omitting most of the rarer mountain species and by simplifying the accounts of such critical genera as *Rubus* and *Hieracium*. The result is very considerably to reduce the time taken in using the keys and substantially to cut down the number of wrong turns that a beginner can take. The book also is a bare three-quarters of an inch thick as against the solid two inches of the original.

In practice, it has been found that even a beginner can identify plants satisfactorily with the aid of the excellent glossary, which has been retained from the original work, and the authors must be congratulated most warmly on having produced such a practical book with up-to-date nomenclature and equally up-to-date information. In these ways their work is beyond criticism. There are, however, two gaps to be filled. The first is illustrations, and this could easily be filled by a companion volume taken from the illustrations to the larger volume, by Sybil Roles, Vol. 1 of which has already appeared. Her line drawings, in this case with only one to the page and with only those species here included, would make an invaluable supplement. Our other need is for a student's flora in Hooker's sense. The present volume could easily be modified for this purpose by the addition of something comparable to Hooker's synopsis of natural orders and natural arrangements of families.

P. Falk

Soil Chemical Analysis

By Prof. M. L. Jackson. Pp. xiv + 498. (Englewood Cliffs, N.J.: Prentice-Hall, Inc.; London: Constable and Co., Ltd., 1958.) 57*s*. 6*d*. net.

THE seventeen years that have elapsed since the publication of Piper's "Soil and Plant Analysis" have seen rapid advances in the subject of soil chemical analysis, notably by the widespread adoption of spectroscopic techniques, and a considerable need has been felt in recent years for an authoritative up-to-date treatment of methods of soil analysis. It is fortunate that Prof. Jackson has undertaken the task of meeting this need, because his diversity of interests and long experience of the complex problems of soil analysis have enabled him to write a book that is much more than a collection of recipes. Within the compass of 500 pages he deals adequately with nearly all the techniques employed in modern soil chemical analysis and also finds space for alternative methods of analysis. This coverage has been achieved by judicious selection of methods and references, concise writing, and good organization of the subject material (every paragraph is numbered to permit cross-reference).

It is easy to criticize a book of this type, and some analysts will undoubtedly question the omission or inclusion of certain procedures. There are a considerable number of typographical errors, the index is rather inadequate, and the relevance of some of the quotations under the chapter titles is obscure. However, these are minor defects, and this work deserves praise rather than criticism. The book is well illustrated, reasonably priced and generally well produced, although a more suitable type of paper could perhaps have been found for a book that seems destined to spend much of its life on laboratory benches.

This work is indispensable to anyone concerned with soil chemistry. It should be particularly welcome to teachers, because it includes suggestions for a laboratory course, pertinent questions at the end of each chapter, and admirably concise discussions of the principles of various methods.

J. M. Bremner

Curare and Curare-Like Agents

Edited by D. Bovet, F. Bovet-Nitti and G. B. Marini-Bettolo. Pp. xi + 478. (Amsterdam: Elsevier Publishing Company; London: D. Van Nostrand Company, Ltd., 1959.) 85*s*.

THIS book is the outcome of an international symposium held in Rio de Janeiro in August 1957. It is very different from previous monographs on curare and from the now familiar pattern of conferences of which the names of the participants can almost be predicted from the title: both the wide scope of the book and the large number of contributors from South American countries are welcome innovations. The home countries of the curare alkaloids have provided specialists reporting on the botany, history and ethnology of curare, on the methods used to prepare the poisoned arrows, on the survival in present days of the use of curare for hunting purposes. Other parts of the book deal with classical organic chemistry, pharmacology and clinical uses of curare and its synthetic substitutes; there are fascinating speculations on the receptor–drug interaction, which is no longer considered as a stable equilibrium but as a dynamic process in which not only the drug but also the receptor may suffer deformation and therefore changes in the course of time. The book is well produced; the autoradiographs (in P. G. Waser's article) of end-plate regions of muscle poisoned with decamethonium are particularly beautiful.

Marthe Vogt

Outline of Historical Geology

By A. K. Wells. Fourth edition revised with the assistance of J. F. Kirkaldy. Pp. xv + 398. (London: George Allen and Unwin, Ltd., 1959.) 32*s*. net.

A. K. WELLS'S "Outline of Historical Geology" was first published in 1937, and was then intended as an introduction to the stratigraphy of Great Britain for the general reader presented in such a way as to stress the cultural or philosophical value of historical geology. Later editions, written with the assistance of J. F. Kirkaldy, enlarged the scope of the work to make it more suitable for the use of students reading for a degree in geology or geography. In the present, fourth, edition, further improvements and additions have been made. A new chapter has been included on the Pre-Devonian rocks of Scotland, which incorporates the results of recent research on Highland stratigraphy and structure. New data on the Pre-Cambrian of Shropshire, on the nature of the chalk, and on the Wealden 'delta' are also included among the revisions that have been made. Selected references now appear at the end of each chapter. Despite the pressure of new facts, the authors have contrived to maintain the emphasis on principles, in accordance with the aim with which the first edition was introduced, rather than the mass of detail into which the teaching of stratigraphy can too easily degenerate.

PREPARATION OF DIAMOND

By DRS. H. P. BOVENKERK, F. P. BUNDY, H. T. HALL*, H. M. STRONG
and R. H. WENTORF, jun.
Chemistry Research Department, General Electric Research Laboratory,
Schenectady, New York

IT would be good to be able to write a paper entitled "The Preparation of Diamond", in which all the factors affecting diamonds were nicely accounted for and the formation of diamond was completely explained. But the work which has been carried out on this problem indicates that diamond can form in several different ways, and that stubborn mysteries still surround some of them. This article, therefore, is more of the nature of an interim report which describes the salient features of the knowledge obtained so far rather than a complete exposition of diamond formation.

All the observed cases of diamond preparation in our laboratory have occurred at pressures and temperatures appropriate for the thermodynamic stability of diamond. Fig. 1 shows a diamond–graphite equilibrium curve. For temperatures up to 1,200° K. the path of the curve has been estimated by Rossini and Jessup[1], Simon[2] and others from thermodynamic data. For temperatures between 1,500 and 2,700° K., the path of the curve has been determined experimentally by observations of the growth or disappearance of small diamond crystals immersed in suitable media[3].

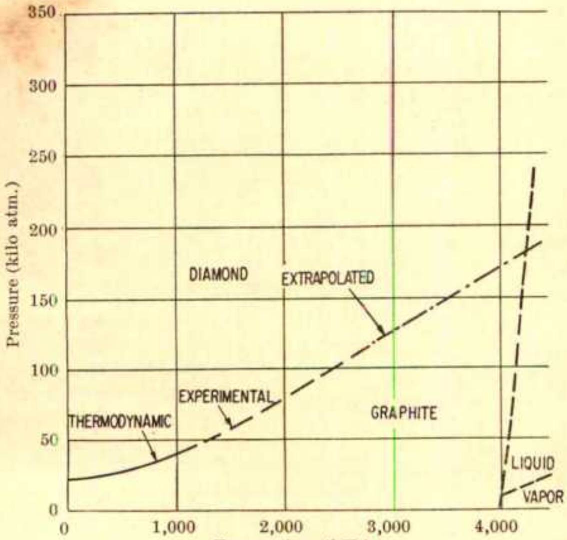

Fig. 1. Carbon phase diagram

The experiments which form the basis for most of this article were usually performed in a tapered piston apparatus capable of very high pressures which enabled us to attain diamond stability at high temperature. Figs. 2a and 2b illustrate the tapered piston 'belt' apparatus which will be discussed in detail by H. Tracy Hall in a separate paper submitted for publication. Many of the most promising systems were examined at several pressure-levels as appropriate apparatus was developed. Diamond does not always form where it is thermodynamically stable; this is what makes diamond synthesis so interesting.

The chemical systems which were studied in connexion with diamond synthesis can be conveniently grouped as follows: (1) direct transition, graphite to diamond; (2) systems involving carbon and oxygen; (3) systems involving carbon as salt-like carbides; (4) miscellaneous chemical reductions; and (5) systems involving carbon dissolved in molten metals.

(1) Direct Transition, Graphite to Diamond

The driving force for this reaction is the increase of density upon going from graphite to diamond. On the other hand, the high heat of vaporization of carbon (more than 100 k.cal./gm. mol.) implies that a high temperature will be necessary before much recrystallization of the carbon occurs. Indeed, the

Fig. 2c. Diamond experiment

usual range of temperatures for forming graphite industrially from petroleum coke, pitch, etc., is about 1,800–2,400° C., and some carbons graphitize only slightly at temperatures higher than these.

Some studies made in this laboratory of the graphitization of diamond at 0·1 and 20,000 atm. showed that the graphitization began at 1,500–2,000° C., depending on the particular diamond, and that, in general, higher temperatures were necessary to graphitize diamond at 20,000 atm. than at 0·1 atm. From the change in rate constant with pressure, the volume of the 'activated state' was estimated at about 160 c.c./mol., and the rate of graphitization, in atoms per second, was observed to be 10^5 times the rate of evaporation for the same temperature. This indicated that the diamonds became graphitized by groups of atoms rather than atom-by-atom. For the reverse reactions, graphite to diamond, it would be reasonable to expect a similar reaction mechanism, because the strong intra-sheet binding forces in graphite would tend to make each sheet behave as a unit (as happens in the formation of 'graphite sulphate' or potassium-graphite). Although the coherent sets of sheets of atoms ('crystallites') in graphite or various carbons contain perhaps only 10^4 or 10^5 atoms, the pressure-volume energy of such a crystallite is large compared to kT at only moderate pressures (20,000 atm.). It is known that in some carbons the crystallites are rearranged only reluctantly to form commercial graphite even at 2,700° C. and 1 atm. Thus the effect of increasing pressure is to slow down greatly any recrystallization of solid carbon, and this slowing-down more than offsets the thermodynamic driving force toward diamond gained by increasing the pressure. Experiments in which graphite was heated at high pressure served to squeeze the microscopic voids from the material, so that its density became nearly the theoretical density of graphite, but no diamond was formed, even at 120,000 atm. Perhaps diamond could crystallize from molten carbon at a sufficiently high pressure; but supposing the melting temperature of carbon to be 4,000° C. at this high pressure, one would estimate by an extrapolation that the required pressure would be in the neighbourhood of 200,000 atm. (The increasing incompressibility of graphite with pressure indicates that the required pressure might be even higher than this.) Such an experiment has evidently not yet been performed.

(2) Systems involving Carbon and Oxygen

Such systems are attractive because they are chemically versatile and tend to favour aliphatic rather than aromatic carbon–carbon bonds. The oxide mineral inclusions in natural diamonds[4–6] suggest that perhaps certain oxides could play a part in diamond formation, perhaps through a shift in the carbon monoxide – dioxide equilibrium. In spite of all these attractive features, only graphite or amorphous carbon ever appeared as products from these systems, with one possible exception. This exception was the reduction of lithium carbonate by lithium metal at high pressures. The carbonaceous residue gave a feeble Debye–Scherrer pattern for diamond and scratched glass in a way characteristic of diamond (tiny helical chips were ploughed out of the scratches). A few tiny triangular faces, 1–10μ on edge, could occasionally be seen but not identified. Further experiments did not produce more abundant or larger crystals.

Other systems which were examined included similar reductions of carbonates, oxalates or formates by metals; the decomposition of iron, molybdenum or chromium carbonyls either pure or in solution in stannic chloride or molten salts; the decomposition of sugars and ketones; the electrolysis of molten carbonates; or finally, the attempted solution and transport of elemental carbon in various molten oxides such as borates, silicates, phosphates, 'blue ground', etc.

(3) Systems involving Carbon as Salt-like Carbides

These systems are attractive because they are comparatively rich in carbon, contain carbon atoms as free ions which could easily be built into a diamond lattice after a simple reduction, and are chemically active at low temperatures. However, only the high-pressure decomposition of lithium carbide by the outward diffusion of the lithium ever yielded any potentially diamondiferous product. The material from this decomposition gave a weak Debye–Scherrer diamond pattern, corresponding to a diamond content of about 1 per cent, and also scratched glass to leave the characteristic helical chips.

Other more disappointing reactions included the decomposition $2MgC_2 \rightarrow Mg_2C_3 + C$, the cyanamide reaction $CaC_2 + N_2 \rightarrow CaCN_2 + C$, the electrolysis of calcium or lithium carbides, and the substitution reaction $SiC + Ge \rightarrow SiGe + C$.

(4) Miscellaneous Chemical Reactions

Carbon disulphide is thermodynamically unstable at ordinary pressures and temperatures. At pressures about 45,000 atm. and 400° C. it was found to change into the black solid described by Bridgman[7]. In combination with various metals used as catalysts or reducing agents, carbon disulphide changed into amorphous carbon at higher temperatures and pressures. Similar reductions of chloroform, carbon tetrachloride or cyanides formed amorphous carbon.

Hannay's method was tried, in which lithium, light hydrocarbons and nitrogen-containing substances were heated together at high pressure. Again only amorphous carbons appeared. The simple thermal decompositions of various hydrocarbons yielded similar products, and no diamond.

(5) Systems involving Carbon dissolved in Molten Metals

These systems turned out to be the most fruitful and also, unexpectedly, the most complex.

In our early work, when available pressures were still less than about 50,000 atm., some experiments

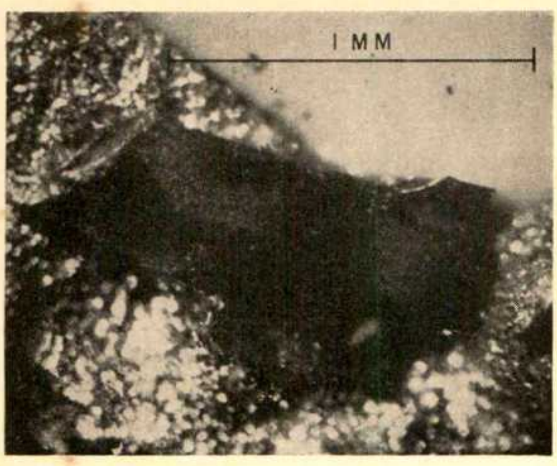

Fig. 3. Diamond in metallic matrix

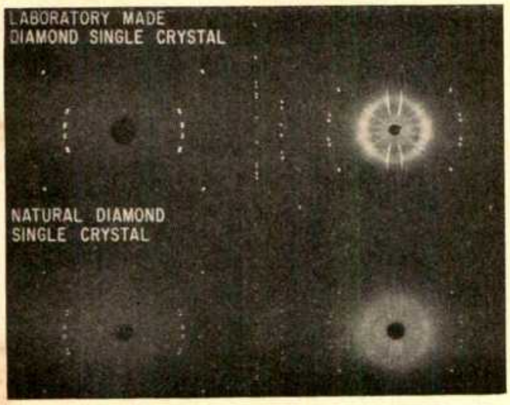

Fig. 4. Debye–Scherrer patterns

were performed with molten aluminium, silver, and even iron. Of course, iron dissolved carbon in appreciable amounts; but the carbon which was precipitated from it was in the form of graphite. No matter how careful the change or how great the fluctuation of temperature, when the pressure was less than 50,000 atm., only graphite resulted. In view of this, it is difficult to see how Moissan's claim to have formed diamond from molten iron–carbon mixtures inside his quenched iron could be sustained, since he could have reached at most only 10,000 atm.[8,9].

A number of experiments were performed using a metallic catalyst and carbonaceous material. One of the first experiments carried out involved heating some seed diamond crystals, iron and a carbonaceous steel-carburizing compound for 16 hr. at about 53,000 atm. and about 1,300° C. (Fig. 2*c*). Out of this there appeared two new diamond fragments with developed crystal faces, each of which was larger than any of the seed crystals. The identification was made by hardness tests and an X-ray diffraction pattern (Figs. 3 and 4). Attempted repetitions of this experiment did not produce diamond. However, it now appears that the iron–carbon system is quite complex at high pressures and temperatures. Several solid phases can form, among them FeC, Fe_3C, graphite and diamond; but which one happens to form depends upon slight variations in temperature, temperature change or chemical composition. Even at 100,000 atm., certain temperature programmes will not permit any diamond to form from iron–carbon mixtures.

Shortly afterwards, a mixture of iron-rich iron sulphide together with carbon and tantalum, as shown in Fig. 5, was heated at about 1,600° C. at about 95,000 atm. The heating time was short, less than 10 min. On the tantalum end disks there formed tantalum carbide, and on top of this lay a black crusty layer of small diamond crystals (Fig. 6). They were identified by their hardness, combustibility and X-ray diffraction pattern. The experiment was successfully repeated many times.

Soon other substances were found to be effective as catalysts for the conversion of carbon into diamond at pressures ranging from 55,000 to 100,000 atm., and temperatures ranging from 1,200 to 2,400° C. They were chromium, manganese, cobalt, nickel, palladium, platinum, etc., or compounds which would react to give the free metals under these conditions, for example, nickel oxide, ferric chloride, etc.

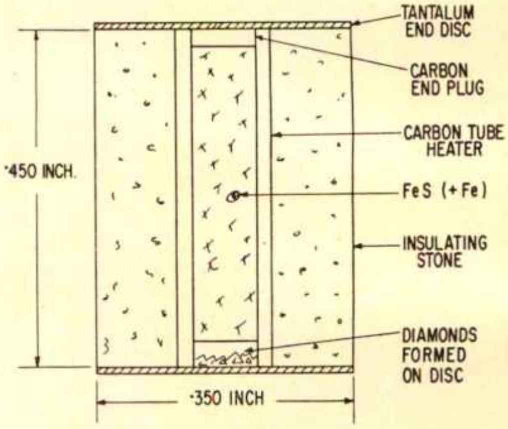

Fig. 5. Diamond experiment

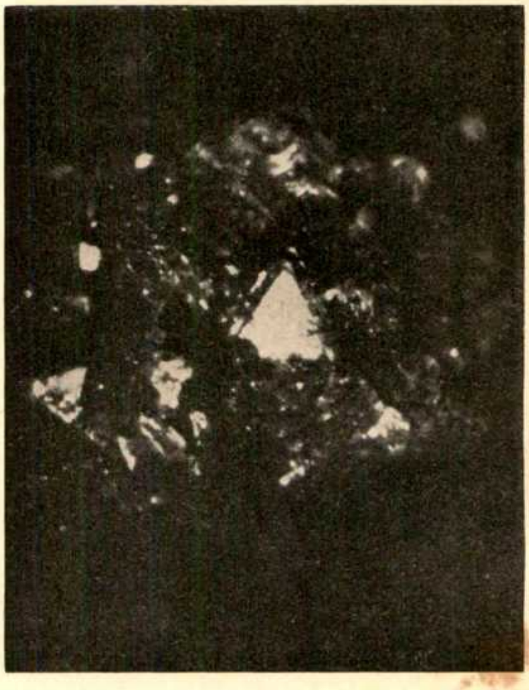

Fig. 6. Cluster of synthesized diamonds

After many experiments it became possible to list some of the conditions peculiar to the formation of diamond.

(1) The pressure and temperature of the system should be those for which diamond is thermodynamically stable.

(2) The temperature must be high enough to ensure that the catalyst metal, saturated with carbon, is molten. Thus the intersection of the melting line of the metal – carbon eutectic with the graphite – diamond equilibrium line sets a lower limit on the temperature and pressure which can be used to form diamond with a particular catalyst. In Fig. 7 the diamond-growing region is shown as a shaded area on the pressure – temperature diagram.

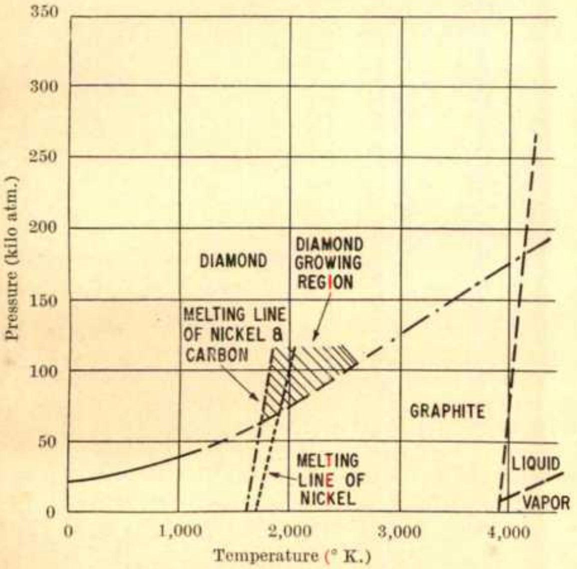

Fig. 7. Diamond-growing region

(3) The catalyst metal can be chromium, manganese, iron, cobalt, nickel, ruthenium, rhodium, palladium, osmium, iridium or platinum. Tantalum is particularly effective for inducing the growth of small diamond crystals, although in some circumstances it may not be as catalytically active as the other metallic catalysts.

(4) New diamond can form whether diamond seed crystals are present or not.

(5) As the synthesis pressure and temperature are moved further into the diamond-stable region away from the graphite–diamond equilibrium line, the rate of nucleation and growth of the diamonds increases and their average crystal-size decreases.

(6) The diamond can grow at very high rates, at least 0·1 mm. per min.

(7) The actual transformation from carbon to diamond occurs across a very thin film, about 0·1 mm. thick, which separates the carbon from the diamond. Thus the transformation is almost 'direct', but the catalyst is essential (Fig. 8). So far it has been found to be very difficult to grow diamond buried in molten catalyst even 1 mm. away from the source of carbon.

(8) Although the main driving force for the formation of diamond is the thermodynamic potential difference between graphite and diamond, temperature gradients can accelerate diamond growth due to the dependence upon temperature of the solubility of carbon in the catalyst.

Fig. 8. Diamond growth from graphitic carbon

(9) The kind of carbon used as a starting material has an effect on the kind and number of the diamonds formed. Good results have been obtained in making diamonds employing ordinary commercial graphite as the starting material. Other carbonaceous material may be employed as the source of carbon, such as carbon black or a sugar charcoal; but graphite is preferred.

(10) Sometimes graphite forms from a carbon-rich melt, particularly when the melt freezes, even though the pressure and temperature are appropriate for diamond stability. Diamond may or may not form at the same time. Apparently the formation of diamond is not a simple process.

(11) The diamonds easily include or grow around foreign particles present in the mixture, particularly at high rates of growth. Often some of the catalyst metal will be thus trapped in a diamond crystal.

(12) The diamond crystal habit varies according to the temperature of formation. Cubes predominate

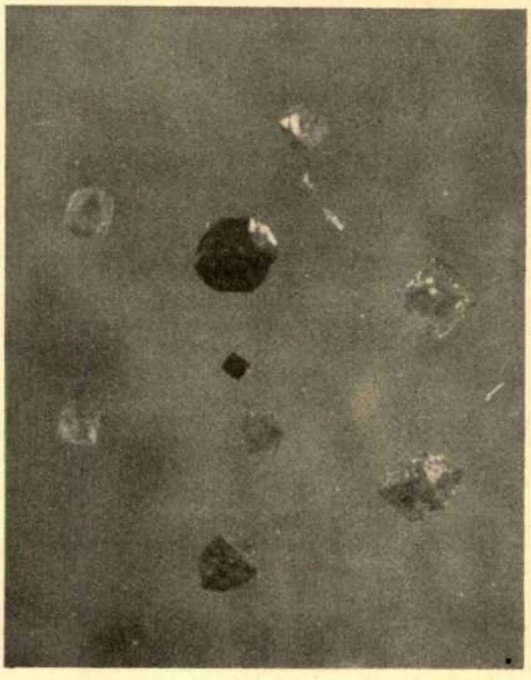

Fig. 9

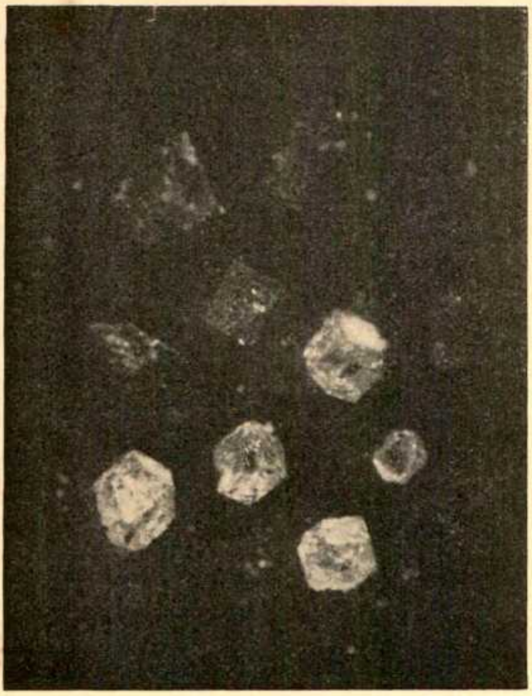

Fig. 10

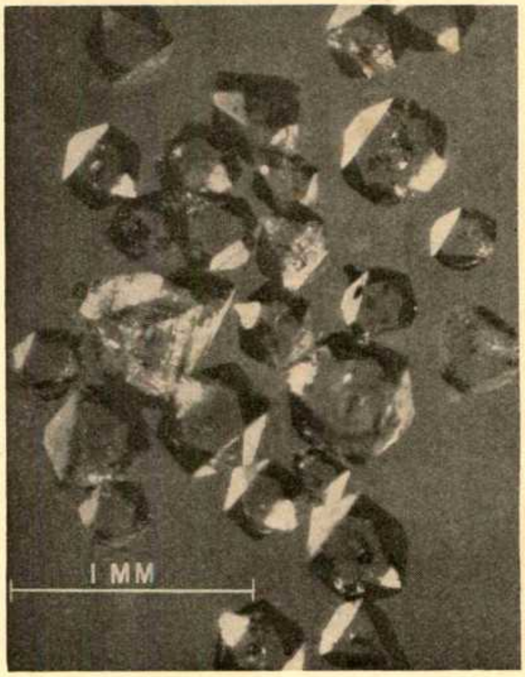

Fig. 11

at the lowest temperatures, mixed cubes, cubo-octahedra and dodecahedra at intermediate temperatures, and octahedra at the highest temperatures. No tetrahedra have been found. At high growth-rates, octahedra are frequently twinned through an octahedral face as a mirror plane. Growth terraces or steps are common on the diamond crystals, but no growth spirals have been found so far. The colour varies from black at low temperatures through dark green, light green and yellow, to white at the highest temperatures. In many cases, the colour does not depend on the particular catalyst used but on the operating temperature relative to the melting point of the catalyst–carbon mixture. Green and yellow colours seem to be associated with imperfections in the diamond crystal lattice rather than with the presence of a specific impurity. Many of the physical characteristics of natural diamonds have been duplicated in the laboratory[10].

Some photomicrographs of various synthetic diamond crystals are shown in Figs. 9–11.

FASCICULUS LIMPIDUS NOV. GEN., NOV. SPEC., A REPRESENTATIVE OF A NEW GROUP OF BACTERIA

By PROF. E. G. PRINGSHEIM
Pflanzenphysiologisches Institut der Universität, Göttingen

A PECULIAR organism, the nature of which puzzled me much at first, was observed in putrefaction cultures inoculated with a small quantity of soil from a dried-up pool not far from Cape Town, South Africa. It contained fragments of twigs and rock along with powdery earth. This soil sample had been very kindly sent to me by Dr. M. A. Pocock, Rhodes University College, Grahamstown, with the idea that it contained colonial Volvocaceae. This was the case: *Volvulina*, a mixothrophic member of the Volvocaceae, together with species of *Chlorogonium*, *Coccomonas* (or *Dimorphococcus*), an undescribed species of *Lobomonas*, an interesting species of the Polytomeae, and others turned up under suitable conditions.

Successful cultures were prepared in the following way: a quarter of a dry pea was put on the bottom of a test-tube, covered with clay soil and water and heated in a steam chamber for 1 hr. on two consecutive days. The following morning, or later, inoculation was done with a small amount of the original soil.

The culture was kept in the light. Other mixtures, such as grains of barley, bits of cheese, a little starch, different kinds of soil instead of clay soil, did not produce the same interesting type of biological community, but only a much more scanty growth without Volvocaceae and the new organism here described.

The original soil, even in much greater quantity, with water or a dilute mineral nutritive solution and trace elements, was still less productive. This is noteworthy, because it is of general application. It shows that the soil sample no longer contained enough of the substances which had originally produced the mixed population, the resting stages of which regained vitality in the tubes prepared as described. It also indicates that heating of the clay soil is necessary for these organisms to find suitable conditions for growth.

In all other instances the various organisms appearing in such putrefaction cultures could be maintained indefinitely by inoculating them into identical tubes without the original soil, in series. Not so the new organism, which also failed to multiply in a considerable number of media with various organic substances usually suitable for the nutrition of colourless flagellates, bacteria, etc. After repeated washing of the new organism before inoculation, such tubes remained clear and sterile.

In the original culture tubes the peculiar organism in question was observed in considerable quantity near the surface of the soil-mud. The experiment was successfully repeated several times with the same and similar soil samples from the Cape Flats, but only when light was admitted did the new organism appear. It consisted of translucent, almost spindle-shaped structures tapering at both ends when inspected with low magnification inside the culture tubes. Later, the new organism swarmed in the higher regions, too, but the water never really teemed with them, and the other organisms mentioned above were always present.

For closer investigation, specimens of the organism were picked up with the capillary pipette and inspected in hanging drops or in mounted preparations. What was mistaken for colourless, finely striated flagellates at low magnification was at high power seen to be composed of long filaments, some of them bent and twisted to form colonial bundles. These were broadly spindle-shaped, often somewhat flattened, with both poles tapering but not strictly pointed (Figs. 2–5). The individual filaments arranged more or less parallel to one another, though converging, did not all terminate at the same point. Under pressure of the cover-slip they tended to spread, the filaments separating (Fig. 11). Indian ink penetrated between the units of the colony. There is, therefore, no gelatinous matter surrounding the whole or glueing the filaments together. They are united in bundles (*fasciculus*) and have a translucent, limpid appearance. The organism will therefore be called *Fasciculus limpidus*.

In suitable conditions the colonies moved along their axes, rotating as flagellates generally do. They did not glide along solid surfaces but swam freely through the water, though more slowly than infusoria or even the majority of flagellates usually do.

The motile colonies may aggregate chemotactically. This became apparent when a quantity of culture fluid in a watch glass was inspected for a longer period. Various motile organisms, such as *Spirilla*, small infusoria and *Coccomonas*-cells, assembled around debris particles, were followed by the colonies of our organism, most of which aggregated after some time at certain points. In such open watch glasses, contained in a Petri dish, *Fasciculus*, poured from a test-tube culture, together with other members of the community, kept only for a few hours and could not be identified the following morning, while *Volvulinopsis* and the others kept moving for a whole week. A probable inference is that *Fasciculus* is micro-aerophil, an idea strengthened by our experience and observations with cultures.

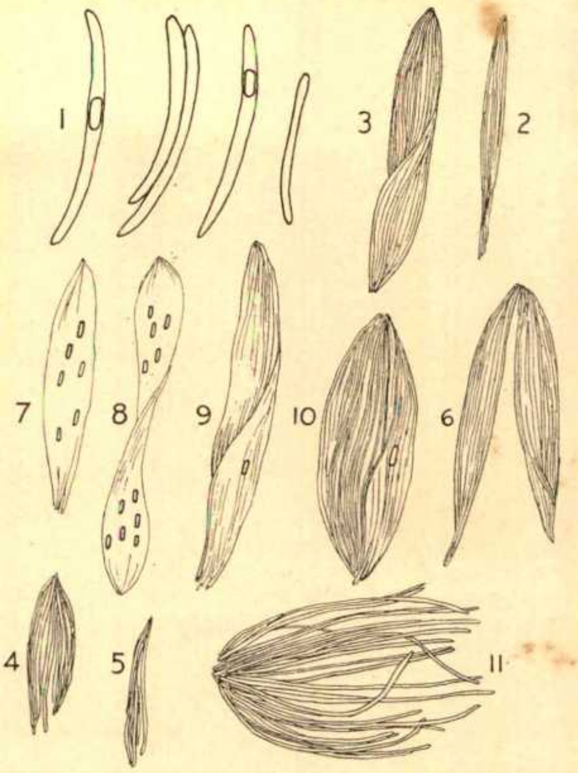

Fig. 1. Individual components of colony mechanically isolated, two of them with spores. 2, Small, narrow colony. 3, Large, twisted colony. 4 and 5, Small, frayed colonies. 6, Rare instance of longitudinally split colony. 7–10, Colonies with spores: 7, colony of the most frequent types—during spore formation, the outlines of the filamentous components have become invisible to a great extent; 8, colony with narrow waist and spore formation; 9 and 10, more or less twisted colonies, each with one spore. 11. Normal colony with filaments separated by pressure on cover-slip. (Fig. 1, × 1,000; others, × 500)

The shape and appearance of the colonies varied (Figs. 2, 4, 5). Apart from the large closely-knit spindles with only slightly frayed ends, there were smaller and narrower ones, and occasionally, though rarely, slightly bent, slender rods which, judging by their optical appearance, belonged to the same organism. Sometimes two narrow spindles cohering at one pole were seen (Fig. 6). Larger, presumably older, colonies had a constriction in the middle, and the filaments were twisted (Figs. 3, 8). The waist is believed to indicate an imminent partition of the colony.

Cells shorter than the total length of the colonies, and others which divided like bacteria, could often be observed. There is little doubt that the units divide after reaching a certain length, and that the daughter cells glide along one another to increase the width of the colonial bundles. I did not, however, find any signs of individual filaments breaking loose from the colonies and starting new ones.

The main mode of reproduction is by spore formation. In older cultures, colonies were found which were more limpid than young ones. Only their outlines were readily observable, while the inner parts of the spindle were optically almost empty except for small cylindrical bodies which by their high refractability, particularly in dark-ground illumination, revealed their nature as bacterial spores (Figs. 7, 8). This was confirmed by their capacity for retaining the fuchsin stain on treatment with acid alcohol.

Later on, transition stages in spore formation were also found in colonies in which the filamentous cell-units were still readily visible. Not all of these formed spores. The spores were usually close to the middle. Their shapes varied from almost oval to, more commonly, cylindrical. Their width was about 1·5μ, their length 5–7μ.

These spores are no doubt the reproductive units responsible for the development of *Fasciculus* from completely dry soil. Their germination could, unfortunately, not be observed because of the failure to cultivate the organism and to separate it from other organisms. It is very peculiar that the individual cell margins vanish almost completely during spore formation, although the whole colony continues to swim about, and its outlines remain clearly visible (Figs. 7, 8).

The structure or nature of the filaments composing the large spindles is also different from that of most bacteria. As already mentioned, optically the organism is fainter than other organisms. In dark-ground illumination it becomes more distinct, and the outlines of the filaments show more clearly than, for example, the outer membranes of Myxobacteria.

These filaments are believed to be cells. They are 2μ across and about 50–100μ in length. They stain with fuchsin and methylene blue, but, in accordance with their low refractability, not strongly. They do not keep the Gram stain, contrary to most bacterial spore-formers. Only the membranes of the spores were stained; they were also more deeply coloured when treated with the Ziehl-Neelsen technique.

The mode of locomotion, rotating and swimming freely through the water, recalled that of flagellates or large bacteria. I did not succeed in demonstrating flagella with the help of Loeffler's technique, of Deflandre's nigrosin method, or dark-ground illumination. Quick drying on fat-free cover-slips or fixing with osmium tetroxide vapour or iodine or Schaudinn's mercury chloride fixation did not make any difference. But I believe this failure was somehow due to inadequate technique, and do not doubt that flagella do exist, since the impression of the swimming movement scarcely allows of any other interpretation.

If this were so, we would have another example of an 'organized' bacterial colony as earlier described for *Vannielia aggregata*[1]. This belongs to the Athiorhodaceae, a family where colony formation had not been known to exist. There, also, many cells are aggregated to constitute a composite unit driven through the water and rotating by co-operation of the flagella; but here the similarity ends. While in *Fasciculus* the units of the colony are long, tube-like structures, those of *Vannielia* are rod-shaped cells radiating from the centre of the colony. Another motile bacterial colony is that of *Chlorochromatium aggregatum*, where again the arrangement of the individual components is quite different. Only one relatively large, central rod possesses a flagellum responsible for the movement of the colony, while the yellowish green small outer cells only adhere to the actively swimming central rod.

It is not possible to include *Fasciculus* in one of the taxonomic groups of the Bacteria. Very long, tubiform cells are known in *Lineola*[2], but this genus does not form colonies, and the production of spores and the appearance of the cells are different. In *Lineola* droplets and other contents are visible under the microscope, and the staining with various dyes is quite normal for a bacterium. *Fasciculus* is much less stainable and the inner part of the cell is almost empty optically. Moreover, the ecological conditions in which the new organism thrives seem to be peculiar. A better insight into its nature could only be obtained by cultivation. I will gladly supply portions of dry soil to bacteriologists who are interested in this creature.

BIOLOGICAL PROBLEMS ARISING FROM THE CONTROL OF PESTS AND DISEASES

THE Institute of Biology has developed a technique for cutting through the hedges which grow up between fields of knowledge as biology undergoes speciation into ever new branches. One of the methods of doing this used by the Institute is to arrange symposia for which the subjects and speakers are chosen with considerable care. Thus, before even a word was spoken in the Royal Geographical Society's well-filled lecture hall on October 1, a look around indicated a successful meeting, for there were many well-known specialists in different fields who seldom previously have found themselves sitting in one room. The subject of this two-day symposium, namely, "Biological Problems arising from the Control of Pests and Diseases", is one of wide and topical interest. The speakers, including those who contributed to several stimulating discussions, were economic entomologists and botanists, medical men and veterinarians, psychologists and humanitarians, in addition to academic biologists.

The symposium was arranged in four sessions, each under a different chairman. This arrangement divided the subject rather broadly into problems associated with arable agriculture, animal husbandry, human disease and health, but the matter presented tended to transcend any grouping. It became apparent that there are many connecting threads between, for example, the drug resistance developed by bacteria and the stimulation to growth of animals consequent on small additions of antibiotics to their diet, that the consequences of malaria control react quickly on the ecological problems of crop and animal pests through changes in human needs, and that too rigid a control of mental deficiency might have a retarding influence on science and art. Several facets of the discussion pointed to the human being as the greatest pest of all One speaker was bold enough to suggest that every pest and disease worthy of the name was, in fact, a human artefact, and given time he might convert almost every surviving wild organism into a pest Although some would scarcely go so far, there were several expressions on the value of maintaining at least some areas of the world in a natural or semi-natural state Thus, in the problem of controlling agricultural pests, reference was made to Elton's plea for ecological diversity if only to provide reservoirs of the predators and parasites of pests.

The stage was set by Mr F C Bawden, chairman of the first session, who directed attention to the unexpected and sometimes undesirable results which follow action against any particular pest or disease of importance in agriculture The control of one may let in another He was unable, however, to quote any case where the secondary trouble had resulted in greater economic loss than the primary one, and therefore concluded that on the whole there was always a net gain This theme was taken up by Mr A H Strickland, of the Ministry of Agriculture and Fisheries Plant Pathology Laboratory at Harpenden He provided a valuable assessment of recent work with insecticides, but neglected the classical work of biological control because it was well covered in a recent survey by Prof G C Varley in a paper before the Royal Society of Arts He instanced cases where eradication of species had been attempted, such as the Colorado beetle from Europe and the Mediterranean fruit fly, which has twice been introduced into and eradicated from the United States, and he pointed out that in Britain no less than a fifth of the acreage of root and some vegetable crops is treated annually with insecticides as a routine measure To those—including many farmers—who deplore the very widescale use of insecticides and herbicides as an excuse for sloppy husbandry, Mr Strickland had some encouraging words about recent studies of the manipulative possibilities such as physical control of the soil by rotovation, and the adjustment of spacing in sowing and planting which can render crops unattractive to pests or stimulate the crop to grow away

Dr. T J Martin, of the Research Station, Long Ashton, dealt with the direct risks to man arising from the fact that fifteen out of the forty-two or so insecticides and fungicides in common usage are in the highly toxic category Study of the risks to spray operators led to the Agriculture (Poisonous Substances) Regulations of 1956, and, in spite of some accidents, it seems that the risks to the consumers of crops which have been subjected to a variety of toxic sprays are under control, at least in Great Britain Discussion revealed that, with the exception of arsenic, for which there is a legal tolerance, the use of any spray on the land in Britain is entirely at the discretion of the manufacturer and the farmer Neither Dr Martin nor any other speaker was in a position to deal with the influence of toxic materials on wild plants and animals or on game, although these largely unknown but important influences were doubtless in mind It is abundantly clear that there is to-day a heavy responsibility falling on entomologists and botanists to obtain and interpret information on the selectivity and tolerance-levels of these chemicals, in order to give advice to manufacturers and users on formulations, dosages and methods of application in such a way that indiscriminate slaughter can itself be brought under control

Mr F G H Lupton, of the Plant Breeding Institute at Cambridge, set a different note by describing some striking successes in controlling diseases through genetical resistance or tolerance, but he mentioned that all too often the plant breeder is called in only when other methods have failed Among other examples he described the ding-dong race which was started in 1912 by Sir Roland Biffen and is still in full cry between the genes of newly evolving races of the rust fungus and resistant genes of wheat sorted out by plant breeders The series Marquis – Ceres – Thatcher – Pilot – Selkirk have so far kept alive the economy of the Great Plains, but the race is still neck-and-neck

The second session introduced several problems from overseas Thus, Mr M Crawford, of the Commonwealth Bureau of Animal Health at Weybridge, emphasized that eradication of a killing disease of livestock, such as rinderpest, could lead to harmful effects from over-population, over-grazing and malnutrition if achieved among peoples who regard stock as a social or religious asset without economic controls Such experience was referred to also by Mr W H Potts, formerly of the Colonial Service, with reference to the control of tsetse flies and trypanosomiasis He was not, however, prepared to support the tendency in recent years to hail the tsetse fly as the preserver of the African soil from destruction by man This theme, like the earlier one on controlling agricultural pests, led to discussion on the advantages or disadvantages of ecological diversity as a background for the economic use of land There is, for example, evidence that in the African semi-arid bush the broad spectrum of wild indigenous fauna, fully adapted to living off the indigenous vegetation at all levels, could, under proper systems of management and annual cropping, produce human food little if any less than is produced by the narrow spectrum of exotic domestic stock At least there is a case for spending money to explore such possibilities in selected areas, rather than to spend all that is available on the blind eradication of wild-life and tsetse flies

The control of human diseases in tropical areas was the subject of two contributions, by Prof T Davey, of the School of Tropical Medicine at Liverpool, and Sir Gordon Covell The latter mentioned that during the World Health Organization campaign there were two hundred teams working in India, each of which looked after one million people. Despite such campaigns, the Organization's figures show that the annual loss from malaria is still a vast one The improvement of physique and of work undertaken by persons in malarial areas is marked, following control There is normally some resistance to malaria, but this resistance is only local, so that an influx of persons from another district may result in severe outbreaks Although Sir Gordon did not say so, this, of course, was known in England during past centuries, when it was noted that a wife from outside taken into such malarial areas as the Fens or Hundred of Hoo was liable to die within a short time, whereas the locals were in balance with their disease

Prof Davey dealt more with the sociological problems expected as a result of the control of such diseases as malaria, and pointed out that nowadays in India the excess of births over deaths is some 15,000 a day In discussing birth control as the biological remedy, he mentioned that certain classes are more amenable to birth-control methods than others, and that in a low-level subsistence type of society every additional member of the family gives another worker, and so a better chance for survival. Where social conditions are better, each additional mouth is a liability rather than an asset. Thus the lower the subsistence-level the greater the birth-rate tends to be.

Dr. E. Slater, of the National Hospital for Nervous Diseases, raised some interesting points about the genetics of mental disease, and pointed out that the discovery of new methods of treatment enabled certain diseases which are transmitted genetically as dominants to increase their proportion in the population. This was simply done by overcoming the biological disadvantages which these dominant genes will contain, provided no treatment is given. Among the interesting points he made were that the manic-depressive type of patient is met with ten times as frequently among scientists as among the rest of the population. This may be a question of either cause or effect. Schizophrenics are found particularly among artists, and in these patients fertility is only 70 per cent that of normal. There is a possibility that this disease may be associated with some genetic advantage. The question whether certain types of mental defective should be sterilized is difficult because it is possible that workers in, for example, the artistic and scientific fields, may show improved output over the normal if they have some minor degree of mental disease.

The problems which arise from drug-resistance in bacteria were treated in a sparkling contribution by Dr. Mary Barber, of the Postgraduate Medical School, London. She pointed out that not all bacteria have taken the massive attack by antibiotics in clinical medicine lying down; in the case of *Staphylococcus diogenes*, drug-resistant strains are now the major bacterial scourge in hospitals all over the world. Resistant strains of bacteria may be drug-tolerant or drug-destroying, and in certain cases may even become drug-dependent. Evidence points to the resistance being genetic rather than adaptive, and that penicillin, for example, has caused a prodigious evolution in the population structure of *Staphylococcus* by simple selection. Those strains carrying resistant genes which formerly were present in a tiny proportion have now increased to 60 or 70 per cent of the population in most hospitals. The same principle applies in the case of insect resistance to the new synthetic insecticides, as explained by Dr. J. R. Busvine, of the London School of Hygiene and Tropical Medicine. In more than a hundred harmful insects resistant strains have occurred, and in some cases the inheritance of the resistant trait has been shown to be of a normal Mendelian type. Whether the trait is 'physiological', which is immune to the poison, or 'behaviouristic', which manages to avoid it, its emergence seems to constitute greatly accelerated evolution on essentially Darwinian lines. Dr. R. Brande, from the National Institute for Research in Dairying at Shinfield, spoke on the recent experiments which show that very small amounts of antibiotics added to the diet of domestic animals increase growth-rate up to 10 per cent and the efficiency of food conversion by from 3 to 5 per cent. He explained that economic advantage of this phenomenon is being taken now on quite a large scale in the United States, although the biological reasons for it are as yet in the realm of conjecture.

The last contribution to the symposium was by Dr. G. C. L. Bertram, from St. John's College, Cambridge, who spoke of 'ethical' or deliberate selection in mankind as having supplanted natural selection. He sketched the sequence of events which led to a doubling of the human population in the past eighty years or so, and the probability that it will double again during the next forty years—European dominance, followed by reduction of strife, the development of hygiene, and the control of biological competitors. Human compassion has led to death control, and now is the time for a great extension of birth control as a further expression of the freedom of choice by the individual. Having accepted Sir James Gray's concluding thought expressed in his presidential address at the York meeting of the British Association that man now has the intelligence and the knowledge to control his own destiny, the question has still to be answered what that destiny is. In a cynical moment, Dr. Bertram compared modern man with a drunkard riding a runaway horse, whereas Dr. A. S. Parkes, who guided this final session from the chair, expressed the hope that our freedom of choice would never become so wide that we would ourselves have to decide whether or not to be born.

E. B. WORTHINGTON

DARWIN'S ILLNESS

By PROF. S. ADLER, O.B.E., F.R.S.

Department of Parasitology, Hebrew University, Jerusalem

DARWIN'S illness, which practically amounted to forty years of invalidism, has given rise to considerable speculation. The doctors who treated him could find no physical explanation for his distressing symptoms and apparently concluded that he was a hypochondriac.

Darwin, whose sufferings were very real, complained in a letter to Hooker "many of my friends I believe think me a hypochondriac". Commenting on this, the late Sir Arthur Keith[1], in his book "Darwin Revealed", remarks emphatically: "Darwin *was* a hypochondriac, a very real one . . .".

Hubble[2] states that "it is apparent that his illness bears the unmistakeable marks of an emotional disorder" and adds, "his psychoneurosis may be regarded as an adaptation to his environment which nourished and protected in the highest degree his uncommon genius". This author[3] justifies his diagnosis on the basis of Darwin's family history. He rightly points out that Darwin's wife was an exceptionally devoted nurse and his son showed a tendency to hypochondria. It may, on the other hand, be argued that the above qualities were acquired and not inherent; chronic invalidism in the head of a family, whatever its cause, has psychological consequences and may well induce in the mother a strong tendency to nurse and protect, and in the younger members of the family an exaggerated fear of disease

Good[4] invokes psycho-analysis and considers the whole of Darwin's symptoms as a reaction to his father's autocratic personality He goes so far as to say, "Darwin's punishment for the unconscious patricide was a heavy one—almost forty years of severe and crippling neurotic suffering which left him at his best fit for three hours' daily work"

Keith accepts the unconscious as responsible for all Darwin's symptoms "In Darwin's case the voluntary part of his brain seems to have too easy and too free an access to his involuntary part Therein I believe lies the source of all his ills " Nevertheless, in referring to one episode of 1873 he writes, "I infer this to be an attack of true angina of the heart"

A purely psychological aetiology for Darwin's illness cannot be accepted as conclusive until all other factors have been eliminated Gaylord Simpson[5] has recently suggested that Darwin suffered from brucellosis There is no direct evidence to refute or prove this theory

It is obvious that all attempts to explain Darwin's symptoms must be based on a detailed analysis of the events recorded in the voyage of H M S *Beagle,* because there is nothing of any medical significance prior to the voyage which could throw light on his subsequent illness As Lady Barlow[6] rightly remarks, "Charles Darwin's forty years of invalid existence moreover were an unexpected sequel to his youthful vigour, for his strength and endurance were well above the average, as Captain Fitzroy has recorded in his account of the various incidents during the *Beagle* voyage"

Darwin was a dedicated geologist and throughout his whole life maintained the keenest interest in this subject Nevertheless, at the age of thirty-three, he was compelled to abandon field work in a favourite subject because he found by experience that the physical effort it entailed exhausted him Is it reasonable to ascribe this sacrifice to a belated reaction to a domineering father ?

There is one very important point in Darwin's case-history which writers on the subject have apparently overlooked

In "The Journal of the Voyage of H M S *Beagle*", Chapter 15, Darwin (March 25, 1835) writes "We slept in the village of Luxan which is a small place surrounded by gardens and forms the most southern cultivated district in the province of Mendoza , it is five leagues south of the capital At night I experienced an attack (for it deserves no less name) of the Benchuca a species of Reduvius, the great black bug of the Pampas It is most disgusting to feel soft wingless insects about one inch long crawling over one's body Before sucking they are quite thin but afterwards they become round and bloated with blood, and in this state they are easily crushed " Darwin observed 'Benchucas' for at least four months and he fed one specimen on a ship's officer "This one feed for which the Benchuca was indebted to one of the officers kept it fat during four whole months , but after the first fortnight it was quite ready to have another meal "

The "great black bug of the Pampas" which attacked Darwin in Luxan can be no other than *Triatoma infestans,* which has become adapted to human habitations and feeds on man and domestic animals throughout extensive regions in South America It is the most important vector of *Trypanosoma cruzi,* the causative agent of Chagas's disease, in the Argentine, Chile and parts of Brazil The province of Mendoza has a relatively high incidence of Chagas's disease, and according to South American colleagues with whom I discussed this problem at the recent congress on Chagas's disease held in Rio de Janeiro during July 5–12 [see p 1114 of this issue of *Nature*], as many as 60 per cent of the population in parts of Mendoza give a positive complement-fixation test for *T cruzi* and as many as 70 per cent of specimens of *Triatoma infestans* are infected with the trypanosome Darwin was therefore definitely exposed to infection on at least one occasion It is highly probable that he was also exposed on other occasions, but he particularly noted the incident in Luxan because of the intensity of the attack of Benchucas , parts of Chile through which he passed show a 10 per cent positive complement-fixation test in the population together with a considerable infestation with infected *Triatoma infestans* We must also bear in mind that Chagas's disease has a very wide distribution in South America from Chile to Mexico (recently a few cases have been recorded in Texas) and the province of Mendoza is an area of relatively high infestation

The incident in Luxan cannot, however, explain Darwin's previous seven weeks severe illness during September and October 1834 which confined him to bed in Valparaiso and commenced during the last week of a six weeks journey Unfortunately, no clinical details of this episode are available Keith writes, "As to the nature of this illness I do not know of any exact information but typhoid fever is a very probable diagnosis" There is not the slightest suggestion of an emotional cause for this incident

The complications and sequelæ of Chagas's disease have been studied in detail by some of the ablest South American pathologists and clinicians, particularly in Brazil, the Argentine, Chile and Uruguay, and considerable literature on this subject is now available Particular attention has been paid to the clinical and pathological aspects of the myocarditis which appears in some victims of the disease Darwin's exhaustion after physical effort can well be explained on the basis of an infection with *T cruzi*

At the above-mentioned congress a number of Brazilian pathologists and clinicians maintained that apart from, and in some cases in the absence of, cardiac complications, Chagas's disease may be associated with clinical signs related to the alimentary tract, particularly the œsophagus, colon and stomach, as a result of damage to Auerbach's plexus They based their conclusion on the high incidence of positive complement-fixation tests in patients with symptoms related to these organs There was no unanimity on this point because although many such cases have been found in Brazil, few or none have as yet been recorded from the Argentine

It is obviously impossible to *prove* that Darwin was a victim of Chagas's disease but two points cannot be overlooked · (1) his symptoms can be fitted into the framework of Chagas's disease at least as well as into any psychogenic theory for their origin , (2) it is possible to pin-point with certainty a definite incident on March 25, 1834, during which he was exposed to optimal conditions for infection with *T cruzi*

OBITUARIES

Mr J T Davey and Mr H. J Morris

In the air disaster at Bordeaux on September 24, the International African Migratory Locust Organization, which exists to prevent the escape of swarms of the Migratory locust from the recognized outbreak area in the flood plains of the Niger south-west of Timbuktu, suffered a very severe blow The fifty-three people killed included no less than eight associated with that Organization Mr J T Davey, aged thirty-six, director of research , Mr H J Morris, aged thirty-six, an experienced scientist newly appointed as an assistant to Mr Davey, and his wife , Madame Duhart, wife of Monsieur A J Duhart, director of survey and control, and one of their children , and Monsieur J J Rey, one of the locust control officers, and his wife and child

James Thomas Davey graduated from the University of Bristol and then took a diploma in agriculture at Cambridge and spent a year at the Imperial College of Tropical Agriculture in Trinidad He first went to Africa in 1947 as an entomologist in the Department of Agriculture in Nigeria, where he investigated the habits and ecology of certain species of biting flies (tabanids and tsetse flies) At the same time, he became interested in locusts, and in 1948 he embarked on a detailed ecological study of the African Migratory locust, partly in association with H B Johnston Particular attention was paid in this study to the neighbourhood of Lake Chad, which was under suspicion as a possible outbreak area and the important conclusion was reached that while the Migratory locust does occasionally swarm there, the Chad area is not comparable as a source of swarms with the recognized outbreak area in what was then the French Sudan

With this valuable experience behind him, he accepted in 1951 an invitation from the International African Migratory Locust Organization to visit the outbreak area on the Niger in order to extend investigations already begun by others of the ecology and seasonal movements of the locust there His secondment to that Organization by the Government of Nigeria for this purpose was extended in 1952 for two years An outcome of this mission was a decision by the Council of the Organization to establish a permanent Research Service Davey became director of it, and he continued in that capacity until the time of his death Through his own ability and personal qualities, including a very thorough practical knowledge of French acquired mainly by usage, the Research Service and its scientific work became integrated into the Organization in a highly successful manner, which could not have been achieved without the respect, affection and support which he won from all his colleagues

His scientific work consisted mainly of studies of the seasonal movements of the locust population in and around the Niger plains in relation to the seasonal rainfall, river-level and flooding of the plains by overflow from the river By means of an impressive programme of field-work which involved the marking of more than a million locusts individually with paints, during a period of four years, and releasing them in particular localities in and outside the plains in the hope of recapturing some of them elsewhere, he succeeded in demonstrating a regular seasonal shift of population (already suspected by G Remaudière, who conducted an ecological study of the locust in the flood plains during 1949–50) between the plains and the surrounding arid country His work further indicated that certain parts of the plains are far more important than others as breeding grounds of the locust A much better understanding of the outbreak area as such has resulted from these investigations, and this has led to important improvements and economies in the supervision and preventive control of the locust

Davey travelled widely in Africa in the course of his duties In 1953 he visited the outbreak areas of the Red locust in Northern Rhodesia and Tanganyika and toured parts of the vast area of eastern Africa over which the Desert Locust Survey, which has its headquarters in Nairobi, operates Recently, he went to the Sudan Republic to see and discuss with the authorities there the circumstances in which a local increase in the population of the Migratory locust had occurred His interests were wide and he was a good companion on journeys in remote places His zest for life and his vigour and resourcefulness enabled him to take in his stride the many difficulties, some of them severe, which arise in 'bush travel' in Africa The wild life of Africa appealed to him greatly He knew the mammals of his areas well and was a keen shot, but he never shot animals solely for the sake of shooting In connexion with his work, he made extensive collections of grasshoppers and plants, and these have added considerably to knowledge of the acridid fauna and the flora of the Niger flood plains and the surrounding country

Fortunately, he made a point of writing accounts of his work at frequent intervals, and very little of the work that he had completed will be lost His most important publications are two long papers on the ecology of the Migratory locust in what he called the Central Niger Delta , these form part of a planned series of three, and it is understood that the third part was virtually complete in typescript when he died It is fitting that this valuable series of papers is being published in *Locusta*, the journal of the international organization which he served so well

The death of 'Jimmy' Davey, while still young, removes a man who was confidently expected to play an important part in the field of locust research and control in the future His wife survives him, with three young children

Hilary Jolliffe Morris graduated from St John's College, Oxford, in 1948 A few years later he joined the Research Division of the Ministry of Agriculture of the Sudan, where he undertook pioneer studies of techniques of control of the Desert locust This work, which covered a period of five years, contributed significantly to the development of aircraft-spraying and of low-volume ground-spraying against locusts, and in the course of it he became familiar with methods for the field-assessment of spray deposits and of the results of spraying operations

In 1957 he joined the Colonial Pesticides Research Unit at Porton Down, near Salisbury, England, where he was occupied for two years in laboratory work on the toxicity of new insecticides to mosquitoes He was essentially a field-man, however, with a strong liking for Africa and a desire to resume locust research, and when a suitable opening occurred in the Research Service of the International African Migratory Locust Organization he applied for the post and was selected

This new appointment was for an investigation of the applicability of modern methods of locust control, particularly spraying from aircraft, in the conditions of the outbreak area of the Migratory locust on the Niger Morris was very well fitted by his accumulated experience and personal qualities for this important task, and he set out with high hopes and keen interest on the journey which was to have taken him to the sort of work that he liked best and considered worth while because of its benefit to Africa

Mr and Mrs Morris had been married only six months when they died

T H C TAYLOR

NEWS and VIEWS

Scientific Adviser to the Ministry of Defence.
Sir Frederick Brundrett, K.C.B, K B.E.

IT has been announced that Sir Frederick Brundrett will be retiring at the end of the year from his post of scientific adviser to the Ministry of Defence, and chairman of the Defence Research Policy Committee, shortly after his sixty-fifth birthday Sir Frederick has had a life-time's association with the scientific aspects of defence, initially within the Admiralty, and for the past ten years of his career dealing with defence science in all its aspects A member of the R N V R in the First World War, he joined the scientific staff of the Admiralty in 1919 and remained at H M Signal School, Portsmouth, until 1937, when he moved to headquarters His remarkable qualities as a scientific administrator and his perception of scientific ability were given full scope during the Second World War, when he made a major contribution to the selection and allotment of scientists to the several departments needing them Since the War his talents for organization have been given full rein at the Admiralty and elsewhere, but his greatest contribution has undoubtedly been in the clarification and stabilization of defence research and development policy as a whole over the past few years His contributions to the rationalization of the research and development programme so as to harmonize the needs of the Services with the national resources have been markedly successful, and a great debt is owed to him for his work in this field What he has accomplished is due to three qualities which he has in abundance a real understanding of Service needs and Service modes of thought, a basic understanding of scientific practices and requirements, and a capacity for hard, thorough and clear-headed work equalled by few and probably excelled by none A distinguished player of games when younger, and an extremely successful scientific agriculturist to-day, it is to be hoped that his advice and his services to the Scientific Civil Service will not wholly end with his departure from the Ministry of Defence

Sir Solly Zuckerman, C.B, F.R S.

SIR SOLLY ZUCKERMAN, who is to succeed Sir Frederick Brundrett as scientific adviser to the Ministry of Defence, is no stranger to either defence or to Whitehall Sir Solly was born in South Africa in 1904, he came to Britain in 1925 and rapidly became known as a distinguished research anatomist He at present holds the Sands Cox chair of anatomy in the University of Birmingham, and he is especially well known for his work on the primates During the Second World War his wide scientific talents were drawn on freely by many branches of the Services, but he was perhaps most closely associated with the Royal Air Force, and he made important contributions to the operational analysis of the effects of bombardment, particularly from the air In the past decade he has combined his work at the University of Birmingham with many other activities, including his duties as honorary secretary of the Zoological Society during a rather stormy period, and with the deputy chairmanship of the Advisory Council on Scientific Policy, towards the work of which and some of its sub-committees, notably the Committee on Scientific Man-Power, he has made a major contribution He succeeds Sir Frederick Brundrett at a difficult time when it may well be that a closer integration between civil and defence science is necessary, and when indeed some re-thinking may be necessary on the balance between the two For this task Sir Solly, by his previous experience, his exceptional ability and warm personality, is excellently qualified

Meteorological Branch of the Canadian Department of Transport: Dr. Andrew Thomson, O.B E

DR ANDREW THOMSON, who on September 25 retired from the post of director of the Meteorological Branch of the Canadian Department of Transport, a position he has held for the past thirteen years, is well known in the world of meteorology A graduate of the University of Toronto, his first studies were in geophysics, and during 1920–21 he was put in charge of investigations into atmospheric electricity during the round-the-world cruise of the Carnegie Institution research ship In 1923 he became director of the Apia Observatory, Samoa and in 1929 aerologist of the Dominion of New Zealand He returned to Canada in 1931 as head of the research division of the Meteorological Service, and assumed charge of the whole service in 1946. Dr Thomson has done much in the international field, especially as a member of the Executive Committee of the World Meteorological Organization and as president of the Regional Association for North and Central America of the World Meteorological Organization A great traveller, who has not only done much to build up an efficient national service but also to promote international co-operation in meteorology, he was made O B E in 1948, and awarded the gold medal of the Professional Institute of the Public Service of Canada in 1952 and the honorary degree of D Sc by McGill University in 1958 He carries into his retirement the best wishes and affection of all who know him

Mr. Patrick D. McTaggart-Cowan, M.B.E.

THE appointment of Mr P D McTaggart-Cowan to succeed Dr Andrew Thomson as director of the

Canadian Meteorological Service comes as no surprise to the world of professional meteorology, for he has been Dr Thomson's right-hand man for many years Mr McTaggart-Cowan, who is forty-seven, was born in Scotland but has spent most of his life in Canada After securing first-class honours in mathematics and physics at the University of British Columbia, he won a Rhodes scholarship to Corpus Christi College, Oxford, where he graduated with honours in natural science He joined the Canadian Meteorological Service in 1936 and quickly became known internationally, especially in relation to trans-Atlantic aviation, then in its infancy During the Second World War he was largely responsible for the development of forecasting at the Canadian end of the ferry flights to and from Britain When hostilities ceased he took an active part in the formation of the body which has now become the International Civil Aviation Organization Among professional meteorologists his name stands high, not only as a forecaster, but also as an energetic and skilful administrator, with a gift of clear thinking and direct speech The future of the Canadian Meteorological Service could not be in better hands

Chemical Engineering at Leeds:

Prof. G. G Haselden

Dr G G Haselden, whose appointment to the new chair of chemical engineering at the University of Leeds has been announced, was educated at Sir Walter St John's School, Battersea, and the Imperial College of Science and Technology, London He graduated in chemical engineering with first-class honours in 1944 and afterwards undertook research under the late Sir Alfred Egerton on problems connected with the liquefaction of methane on the results of this work he was awarded his Ph D In 1949 he was appointed lecturer and later senior lecturer in low-temperature technology in the Department of Chemical Engineering of the Imperial College In addition to his teaching duties, Dr Haselden has during the past ten years built up an active school in low-temperature research His main fields of interest have been in the liquefaction of natural gas, the development of new or more efficient gas-separating processes and refrigeration cycles, and the measurement and correlation of the thermodynamic properties of mixtures In 1958 he was awarded the Lightfoot Medal of the Institute of Refrigeration for his work on mixed refrigerants Dr Haselden was one of the founder members of the Low Temperature Group of the Physical Society, and he is a member of the Education and Papers Committees of the Institution of Chemical Engineers and a member of the Research Committee of the Institute of Refrigeration

Illuminating Engineering Society Award:

Dr J. W. T. Walsh

To mark the occasion of its golden jubilee, the Illuminating Engineering Society has instituted an award to be known as the Illuminating Engineering Society Gold Medal, which will be bestowed at intervals of not less than two years for outstanding contributions to the advancement of lighting Recipients of the medal may be of any nationality and need not be members of the Society At the meeting of the Illuminating Engineering Society held in London on October 13, the first award of the gold medal was made to Dr J W T Walsh, who is without doubt the most outstanding and highly esteemed person in the world of lighting to-day. From Merton College, Oxford, Dr Walsh went to the Department of Photometry of the National Physical Laboratory until he retired in 1951, having been there for thirty-eight years His first outstanding contribution was the making of a large-scale photometric survey of factory lighting for the Home Office Departmental Committee in 1913 During subsequent years, he supervised much important work relating to the principles of good lighting and to the design and performance of lighting equipment, and he published a number of papers on all aspects of photometry and illuminating engineering Dr Walsh served for many years as chairman of the British National Illumination Committee and has participated actively in the meetings and work of international bodies concerned with lighting He has served as honorary secretary and vice-president of the International Commission on Illumination and was president of that body from 1955 until June 1959 He has been a member of the Illuminating Engineering Society since 1923, he is the only member who has served two terms as president of the Society (1929 and 1947) He was chairman of the committee responsible for the current codes of practice for street lighting Dr Walsh has indeed been a prodigious worker in the cause of better lighting and this together with his high principles and strict regard for scientific accuracy has endeared him to lighting people all over the world. There is no doubt that his contributions to the advancement of lighting have been truly outstanding

Royal Australian Chemical Institute:

Mr C. E. C Nicholls

Mr C E C Nicholls has been elected president of the Royal Australian Chemical Institute He was born and educated in England, and gained his degree in the University of London with honours in chemistry After spending about two years with the British-American Tobacco Co, Ltd, he joined the Distillers Co, Ltd, in October 1929, very shortly after the latter company had entered the chemical field He spent some years at the Company's main factory in Hull, and brought into operation the first synthetic acetic acid plant in England Early in 1942 he was sent to Australia, where he played a major part in establishing the war-time synthetic acetone production Early in 1945 Mr Nicholls returned to England, where he resumed duties with the Distillers Co, Ltd He made a short visit to Australia in 1946, and again in 1947 when the Colonial Sugar Refinery and the Distillers Co, Ltd, obtained a larger interest in Robert Corbett Pty, Ltd He is at present manager of Colonial Sugar Refinery Chemicals Pty, Ltd, and a director of Robert Corbett Pty, Ltd He was elected a Fellow of the Royal Australian Chemical Institute in 1947, holding office as president of the New South Wales Branch for two years and during the last year of this term he was also vice-president of the Institute

Atomic Energy Authority's Thermonuclear Programme

The United Kingdom Atomic Energy Authority is seeking the necessary approvals to acquire and develop a site of some 175 acres within the perimeter of the Royal Naval Airfield at Culham, Oxfordshire, for development as a new research establishment The new establishment would be for research into controlled thermonuclear reactions and plasma physics and the study of nuclear fusion as a possible source of industrial power Most of the thermonuclear research now carried on at Harwell and Aldermaston will be moved to the new establishment One of the immediate tasks at the new site, if approved, would be the construction of I C S E (Intermediate Current Stability Experiments), a large machine which (as announced at the Authority's annual press conference in July) will incorporate the results of experience with *Zeta* and of other studies in this field, both at home and abroad It is planned that the total numbers employed at the proposed new establishment will rise to 1,000 and that this figure will be reached within four or five years

Divorce Statistics in Britain

THE principal changes that have been introduced in the Civil Tables of the Registrar General's Statistical Review for 1957 which has been published recently relate to divorce statistics (The Registrar General's Statistical Review of England and Wales for the year 1957 Part 2 Tables, Civil Pp xii+200 London H M Stationery Office, 1959 11*s* 6*d* net) Figures for divorces and annulments are now given by calendar year of marriage and age of spouses at marriage, so that the risk of divorce of different marriage cohorts may now be computed, and there are some other welcome new details on divorce An appendix shows details of marriages by manner of solemnization in different countries It is intended to publish this table at five-yearly intervals, and these data give a useful indication of the distribution of different religious groups in the country It is of some interest that the proportion of civil marriages shows a fall, compared with 1952, for the first time since such marriages were instituted in 1836 In addition to these new figures, more detailed fertility tabulations giving better exposed-to-risk are also included in this volume

Sex Research

THE Division of Medical Sciences of the National Academy of Sciences—National Research Council is accepting applications for grants-in-aid of research for consideration by the Committee for Research in Problems of Sex The funds for support of this programme are provided by the Rockefeller Foundation and the Ford Foundation The Committee is concerned primarily with encouraging research on the mechanisms underlying sexual behaviour, with special emphasis on the higher mammals and man Proposals involving endocrinological, neurological, psychological, anthropological, phylogenetic and genetic studies directed toward this objective are therefore invited Requests that deal with the physiology of reproduction or with related biological and biochemical fields should be addressed to the Committee only if they give promise of shedding light upon behavioural mechanisms Preliminary inquiries should be addressed to Room 411, Division of Medical Sciences, National Academy of Sciences—National Research Council, 2101 Constitution Avenue, N W , Washington 25, D C Completed applications for the fiscal year 1960–61 should be postmarked on or before January 15, 1960

Variation in Lizards of the *Leiocephalus cubensis* Complex in Cuba and the Isla de Pinos

Leiocephalus cubensis Gray has been regarded as one of the four species of this genus in Cuba and the Isla de Pinos, and has been known to occur throughout both islands in suitable habitats Albert Schwartz has collected 388 specimens and studied additional material from various museums , this has resulted in the partition of *L cubensis* into two species, each with four subspecies *L cubensis* is now known from Cuba and the Isla de Pinos, the Doce Leguas keys, and the Archipiélago de los Canarreos, where the new species, *L stictigaster*, occurs in western Cuba and the Isla de Pinos The status of Oriente lizards of this complex remains uncertain Schwartz believes that *stictigaster* and *cubensis* arose from a common stock through isolation on western and central island masses during the Oligocene and Lower Miocene Periods With the re-establishment of the island to approximately its present outline between the Lower and Middle Miocene, these two species extended their ranges gradually from the regions of differentiation From modern distribution it appears that the gap between western *stictigaster* and eastern *cubensis* may not yet be closed *L cubensis* also has spread to the east into Oriente as well as the west into Matanzas and Habana (*Bulletin of the Florida State Museum, Biological Sciences*, 4, No 4 , 1959).

Transparent Sintered Alumina—'Lucalox'

SINTERED or vitrified ceramic materials of polyphase composition are normally opaque owing to scattering of light by the different refractive indices of the component phases Single-phase sintered ceramics are usually both opaque and porous owing to the difficulty of sintering refractory substances sufficiently well to produce optical contact between the grains The General Electric Co of America announces the experimental production of a material, under the trade name 'Lucalox', which is formed by pressing from alumina powder of small grain size and fired under conditions, presumably *in vacuo* and at a very high temperature, which permit almost complete sintering to occur The product is non-porous and sufficiently transparent for print to be read through a thickness of the material in contact with the paper Objects viewed at greater distances are, however, blurred as though through frosted glass It retains the refractory qualities of alumina, and is said to be stable up to about 1,900° C Possible fields of use include envelopes for high-intensity light or radiant heat sources, as a superior alternative to fused silica Light-transmission in the visible spectrum, through an unstated thickness, is said to be 90 per cent Since the material is in effect a polycrystalline sapphire, it may offer an alternative to synthetic mono-crystalline sapphire for instrument bearings Its electrical properties are not stated, but would presumably resemble those of sapphire , a permittivity of about 9 5, loss angle between 10^{-4} and 10^{-3} at room temperature, and appreciable conductivity appearing around 300–500° C , depending upon purity The problem of production as a commercially satisfactory operation is said to be still under investigation

International Conference on Non-Destructive Testing

THE third International Conference on Non-Destructive Testing will be held in Tokyo during March 15–21 The Conference is intended to provide an opportunity for the exchange of information on the latest development in scientific research and industrial application in non-destructive testing in different parts of the world and for the discussion of improvements in testing techniques It will also deal with problems of international co-operation The main part of the Conference will consist of four principal sessions (two in Tokyo and two in Osaka) and a number of technical sessions Further information can be obtained from the secretary of the British National Committee for Non-destructive Testing, 1 Birdcage Walk, London, S W 1

University of Texas Grant for Genetic Research

THE University of Texas has received a grant of 1,482,480 dollars, to boost basic research in genetics and cell biology over a five-year period, from the National Institutes of Health, the Public Health Service research centre at Bethesda, Md The grant will support research in the areas of population genetics, genetic effects of radiation and cosmic rays, chromosome studies of cancer and normal cell strains, cytogenetics, and the physiological and biochemical aspects of genetics Seven principal investigators, their associates and assistants working in the Genetics Foundation of the Department of Zoology, will conduct the research Principal investigators will be Prof W S Stone and Drs C P Oliver, R P Wagner, J J Biesele, M R Wheeler, B H Judd and H S Forrest, all members of the University's Genetics and Cell Biology Group

Royal Meteorological Society Officers for 1959–60

THE following have been elected officers of the Royal Meteorological Society for 1959–60 *President*, Dr J M Stagg, *Vice-Presidents*, Dr H L Penman, Prof P A Sheppard, Dr G D Robinson and Dr R M Goody, *Vice-President for Canada*, Dr W L Godson, *Vice-President for Scotland*, R Cranna, *Treasurer*, B C V Oddie, *Secretaries*, P J Meade, Dr R S Scorer, J S Sawyer (editor) and Dr A G Forsdyke (librarian)

University News

Cambridge

MR G R CROWE, who joined the Cavendish Laboratory more than fifty years ago and was well known as personal assistant to Lord Rutherford, has had conferred on him the honorary degree of M A

Leeds

THE following grants are announced from the Department of Scientific and Industrial Research, £1,835 towards the cost of cosmic-ray research in the Department of Physics, £12,000 over three years for an investigation into high-pressure chemistry and geochemistry in the Department of Chemistry, £3,000 over three years for research by Dr P Gray in physical chemistry, and £1,050 for research in high alumina cements in the Houldsworth School of Applied Science, 6,000 dollars a year for two years from W R Grace and Co, of the United States, for a research fellowship in physical chemistry, £1,422 from the Marine Biological Association for research on the electron microscopy of marine flagellates, £3,000 for 1959–60 from the National Coal Board, North-Eastern Division, and £1,000 from Richard Sutcliffe, Ltd, for research in mining, and from the Agricultural Research Council for two research projects, £1,893 in the Department of Agriculture and £2,807 for research into the interpretation of fibre types in sheep in the Department of Anatomy

Lectureships are announced as follows Mr D I Davies (Department of Organic Chemistry), Mr A R J Gaskin (Department of Geology) as from October 1, Mr A N Hillas (Department of Physics), Mr M D Longfield (Department of Mechanical Engineering) as from January 1, 1960, Mr A R Mathieson (in the chemistry of high polymers in the Department of Textile Industries) from January 1, 1960

London

THE title of professor of virology in the University of London has been conferred on Dr Forrest Fulton in respect of his post at the London School of Hygiene and Tropical Medicine The title of professor of epidemiology in the University of London has been conferred on Dr D D Reid in respect of his post at the London School of Hygiene and Tropical Medicine The title of reader in pharmaceutics in the University of London has been conferred on Dr D Train in respect of his post at the School of Pharmacy

Announcements

MR ERNEST TURNER JONES, deputy controller (Overseas Affairs) Ministry of Aviation, has been elected deputy chairman of the Nato Advisory Group for Aeronautical Research and Development Mr Jones is the first deputy chairman to be appointed by the Group, of which Dr Theodore von Karman has been chairman since its inception in 1952

DR NORMAN G GAYLORD, vice-president of research and development of the Polymer Division of the Western Petrochemical Corporation and a senior lecturer at the Polytechnic Institute of Brooklyn, has been appointed editor of *Resins, Rubbers, Plastics*, the loose-leaf abstract service issued monthly by Interscience Publishers, Inc, New York It is hoped to accelerate the publication of abstracts of foreign as well as American articles, and the organic aspects of polymer chemistry will be given a greater emphasis than in previous volumes The subscription price of *Resins, Rubbers, Plastics* is 90 dollars

THE third Australian Nuclear Research Foundation Summer School for Science Teachers is to be held during January 11–20, 1960, at the University of Sydney Each science teacher attending the School is to be paid an amount to help defray expenses he may incur in so doing The total costs of the 1960 School will be in excess of £13,000 The following donations have been made towards these expenses Philips Electrical Industries Pty, Ltd, £3,500, Ampol Petroleum, Ltd, £2,500, W D and H O Wills (Australia), Ltd, £3,500 Further information can be obtained from Dr S T Butler, Department of Physics, University of Sydney, Sydney, New South Wales

ERRATA We regret that one of the names appended to the communication entitled "Light-induced Production of Carotenoid Pigments by *Cephalosporia*" in *Nature* of August 29, p 741, was incorrect, the authors are "R C Codner and B C Platt"

In the communication entitled "Bence Jones Proteinuria associated with a Transplantable Mouse Plasma-Cell Neoplasm" in *Nature* of August 22, p 654, column 1, par 2, lines 4 and 8, for "α-globulin" read "γ-globulin", par 6, line 3, for "β-globulin" read "γ-globulin" Footnotes 4 and 8 should read "Fahey, J L " and "Osserman, R M ", respectively

MELLON INSTITUTE

REPORT FOR 1958–59

THE annual report of the chairman, M B Ridgway, to the Board of Trustees of the Mellon Institute for the year ended February 28, 1959, records an increase in the Institute's independent research staff from 22 to 56, while a further 254 scientists and their assistants were engaged on the 47 industrially sponsored applied science fellowships and projects at the close of the year (Scientific Research in Mellon Institute 1958–1959 Pp x+38 Pittsburgh Mellon Institute, 1959) A plan was developed for industrial affiliation with the fundamental research sector of the Institute's programme whereby co-operation can contribute to the support of fundamental research in a designated area

During the year the independent research programme embraced studies of some of the properties of a group of esterases, with special reference to the cholinesterase of human blood plasma A rapid ultraviolet spectrophotometric method was developed for the assay of hydrolysis of certain substrates and evidence obtained that promotion of enzyme activity depends partly upon a competition between the activator and the substrate for a negatively charged site on the enzyme Studies of fibrogenesis in collagen solution were undertaken to explore the spatial arrangement of the protein amino groups which are regarded as responsible for the characteristic bands observed in collagen fibrils with the electron microscope Investigations continued on the mechanism of enzymatic hydroxylation and on the chemical structures of two metabolites of *p*-aminobenzoic acid

In inorganic chemistry the relatively little-known chemistry of osmium was studied, and besides the discovery of univalent osmium evidence for a zero-valent osmium complex was obtained For studies of the magnetic properties of transition metal compounds a magnetic susceptibility balance was set up, utilizing a 'Varian' 4-in electromagnet and a vacuum microbalance A further programme is concerned with the formation, reactions and structures of inorganic species containing cation–oxygen, cation–hydroxyl and cation–water linkages, while studies in the chemistry and physics of natural and synthetic macromolecular substances continued to develop The contribution of the chain configuration to the internal energy of a polymer has been determined from the dependence on temperature of the stress of the cross-linked polymer This occurs when stretched in the amorphous state, and for polyethylene and poly*iso*butylene this energy effect can be correlated with independently estimated energy differences between the principal bond conformations Stress–temperature measurements on fibres prepared from muscle by extraction and chemical cross-linking can be satisfactorily interpreted as due to reversible melting and crystallization processes Studies on branched-chain polymers have sought to synthesize molecules of precisely known structure and to correlate their physical properties with the chain architecture. These included a theoretical analysis of the distribution of molecular weight resulting from the formation of branched molecules, while investigation of the statistical thermodynamics of dilute polymer solutions continued A theoretical study of the diffraction pattern of a crystal containing a single dislocation indicates that it is doubtful whether or not double-crystal spectrometer measurements can be used to obtain dislocation densities from first principles

In the fields of organic chemistry the structure of the alkaloid skytanthine has been firmly established by a combination of classical degradation and instrumental methods The existence in cyclic sulphite esters of a stereoisomerism arising from the non-coplanarity of the sulphite group has been demonstrated by a nuclear magnetic resonance method The kinetics of the dehydrohalogenation and rearrangement of 1 1-diarylhalogenoethylenes have been studied and also the possible extension of the reaction to purely aliphatic and alicyclic systems Installation of a 'Varian' dual-purpose nuclear magnetic resonance spectrometer operating at 60 Mc /s has greatly assisted the solution of many organic analytical problems From July 1, 1958, the half-time responsibility for service research in the Institute's former Department of Research in Chemical Physics was transferred to the newly established Research Services High-resolution infrared absorption measurements have been conducted by the matrix isolation technique at temperatures as low as 4 2° K on the photolysis products of ammonia, 1 2-diazine and azomethane, survey spectra of about 150 inorganic salts containing polyatomic ions have been obtained in the cæsium bromide region (700–300 cm^{-1}) using a special long wavelength infra-red spectrometer and a Raman apparatus with red excitation Crystal diffraction studies of simple organo-silicon compounds are being pursued, the structure of dicobalt octacarbonyl is under investigation for information about the bonding of the cobalt atoms, while new relations between thermodynamics and continuum mechanics have been revealed in an investigation of the axiomatization of thermodynamics Current studies in radiation research include the radiation decomposition of hydrocarbons, using gas chromatography for analysis, the kinetics of photochemically produced free radicals and the radiation-induced cross-linking of polymers in solution During the year five fellows were appointed in organic chemistry

Fellowship investigations under 'metals programme' include the thermodynamics of systems of importance to the steelmaker, a long-range research and development programme to evaluate ferrous alloys for high strength, particularly at high temperatures, and the physical metallurgy of semi-conductor devices Continued attention was given by the Artists' Materials Fellowship to the fading of pigments and loss of solubility of varnishes in light The chemical hygiene fellowship is giving increased attention to the safety of food additives Under the water pollution abatement fellowship a paper chromatographic technique has been developed for determining fatty acids in water, and a continuous counter-current extractor is being used to recover soluble organic matter from river water Under the organic synthesis fellowship, heterocyclic derivatives, such as imidazolines, hexahydropyrimidines and perhydrotriazones, which give excellent crease resistance to cotton, have been prepared; the study of emulsion paints comprising homo- and co-polymer systems has indicated a correlation between water-resistance, hardness and flexibility of latex films, and polymer composition; and the investigation of polyethers from polyols and propylene oxide has assisted the rapid growth of the polyurethane foam industry. Both the coal chemicals fellowship and the petroleum fellowship cover a wide field and, under the power rectifier fellowship, laboratory development of the first new power rectifier was completed and the growth of highly perfect single crystals of silicon and germanium has been studied. New organosilicon compounds, monomers and polymers have been prepared under the silicones fellowship, including some hybrid organotin organosiloxane compounds.

LABOUR TURNOVER

LABOUR turnover has been a subject of inquiry and discussion since interest was first focused on the problem during the First World War. It is commonly regarded as a source of serious economic waste. The level of turnover in a firm is often regarded as an index of morale among the employees.

Research workers have attempted to analyse the causes of labour turnover by relating it to different groups of factors. The most important of the external factors are the level of employment and the availability of alternative work. The internal factors are the composition of the labour force itself, that is to say, whether men or women are employed, whether they are skilled or unskilled, the length of time workers have been employed, their age and the location of their homes. Wage rates, hours and conditions of work and the personal relationships existing within a firm may also have important effects on labour turnover.

The findings of research do not appear to have helped managements very much in their efforts to reduce labour turnover. The British Institute of Management survey of 1949 and 1950, covering approximately two hundred companies, showed annual labour turnover rates varying from 13 per cent to 59 per cent for men and from 24 per cent to 75 per cent for women per annum. These are industry rates. Individual companies fluctuated below and above this range. Labour turnover was calculated on the basis of

$$\frac{\text{Number of leavers in period under review}}{\text{Average number of persons employed during same period}} \times 100$$

Commonly agreed facts about labour turnover are that in any given period it is heavier among short-service employees than among those of longer service and that much of it does not represent true mobility but, from the social point of view, useless changes from one job to another.

What has not been established is to what extent labour turnover matters to the individual company and to society and the extent to which labour turnover can be measured in financial terms or whether its effects are largely intangible and in any event non-financial.

Excessive labour turnover is assumed to cause waste and inefficiency. Few studies have attempted to find out what exactly is the extent of this waste. One of the drawbacks is the difficulty of measurement. The effects of labour turnover are widespread and varied and attempts to assess them in financial terms can easily become either over-simplified or over-imaginative and remote from verifiable facts.

An appraisal of the importance of labour turnover to industry cannot be complete unless there is some estimate of its financial effects. Certain effects as, for example, the impact on the morale of the working group of a continually changing labour force, cannot be assessed in financial terms. The more tangible costs are also important.

What has been needed is a series of published case-studies of the experience and of the financial cost of labour in individual concerns. The British Institute of Management has now published a series of sixteen such studies*. The studies have been of the cost of labour turnover among direct production workers. No studies have been undertaken among clerical or selling staff.

The data provided by these case-studies and by supplementary information obtained from a large number of firms show that:

(1) In five out of sixteen studies, labour turnover was adding 10*s* or more per week to the wage cost of each individual employed.

(2) The main factors which appear to affect labour turnover cost are the impact of learners on production, the extent to which saleable production is lost through labour turnover and the methods used to make up production losses.

(3) The amount spent on training, induction and interviewing is a matter of company policy and will naturally affect the level of its labour turnover cost. Money spent in this way, however, has a constructive result and is not waste, as is the cost arising from other categories.

(4) Labour turnover has certain long-term effects which are not measurable in financial terms. Most important of these are the effect of high labour turnover on the morale of the work force, the wear and tear on supervisory staff and the loss of customers' goodwill by failure to fulfil orders and to meet delivery dates. To combat these effects by reducing labour turnover, it seems worth spending money on training, induction and interviewing.

(5) Labour turnover appears to be most costly in those firms where there is a high proportion of semi-skilled jobs peculiar to the company itself. This is because the training period is often long and it is rare to find new employees with experience of similar work. The recognized skilled occupations and the relatively unskilled ones, for example, labouring and cleaning, do not involve companies in high training costs.

(6) The results of the inquiry as a whole suggest that keeping labour turnover low may be a relatively expensive business, almost as expensive as allowing it to increase with consequent increased production costs and sales losses. The decision about how much to spend on reducing labour turnover must be based not only on the figures of tangible waste but also on management's estimate of the seriousness of the non-financial aspects.

T. H. HAWKINS

STRONTIUM-90 IN HUMAN DIET

RESPONSIBILITY for estimating the contamination of food by radioactive fall-out has now been transferred to the Agricultural Research Council. The report, "Strontium-90 in Human Diet in the United Kingdom, 1958" (London: H.M. Stationery Office, 1959. 4*s*.), thus continues the series formerly issued by the Atomic Energy Authority.

The general level of radioactivity in food in the United Kingdom for 1958 was small, comparable with that found in the United States, and well below any danger-level. Most of the radioactivity in milk and dairy products, bread and flour, and in leafy and root vegetables, was brought about by the deposition of radioactive debris on the leaves of herbage and crop plants during periods of rain, followed by foliar absorption of (in particular) strontium-90. Only the material deposited during the two months before herbage was eaten by cows or before crops were harvested appeared afterwards in appreciable amounts in human food. Once the debris penetrated into the soil, its 'availability' to plants was greatly reduced. Consequently, the accumulation of available strontium-90 in the soil since nuclear weapon testing commenced in 1945 had been slight.

The radioactivity of milk was highest in western areas of Britain and appeared to be related to the distribution of rainfall. The level of radioactivity increased in all areas during the latter half of 1958, partly as a result of an unusually high rainfall and partly of an increase in the number of nuclear tests.

Examination of certain upland areas that are characterized by high rainfall and by slow growth of herbage had shown that milk from these areas often contained very high levels of strontium-90. This could not be accounted for entirely on the basis of high rainfall, low soil-calcium, and low production of herbage per acre. It was thought that strontium-90 must become entrapped in the mat of vegetation and roots at the base of the sward, and be held available to the plant in successive seasons, in a way not observed on lowland pastures.

The report shows that when strontium was absorbed from the diet, it tended to replace calcium in bone tissue. High levels of strontium-90 in bone could damage the bone or bone marrow, ultimately causing tumours, leukæmia, or other bone diseases. However, it appeared that the replacement of calcium by strontium-90 in new bone tissue was governed not by the amount of strontium-90 in the diet but by its proportion relative to calcium (expressed as micro-microcuries of strontium-90 per gm. calcium). Furthermore, the human body, in absorbing mineral substances from the digestive tract, discriminated against strontium, so that the ratio of strontium-90 to calcium which was found in bone was only one-quarter of that in the food eaten.

The report also discusses other factors which tended to reduce the ratio of strontium to calcium in the diet. Thus, the cow discriminated against strontium when producing milk from grass, so that the proportion of strontium-90 to calcium in milk was only one-seventh of that in the herbage eaten. Leafy vegetables appeared to absorb strontium less efficiently than herbage, and contained correspondingly less radioactive material. Although wheat contained a fairly high proportion of strontium-90, milling, as in the preparation of white flour, removed much of the calcium and strontium in bran and offal, while the subsequent addition of strontium-free chalk as a calcium supplement further reduced the proportion of strontium to calcium in bread and flour products. The report noted that the ratio of strontium-90 to calcium in diets based on wholemeal bread was likely to be higher than average, as there was no legal requirement to add chalk to wholemeal flours, while the milling process did not tend to remove any of the strontium contained in the grain.

However, even on the most unusual food and living in the wettest area, no one in the United Kingdom was likely to consume a diet containing more than 23 μμc. of strontium-90 per gm. calcium, about half the ratio (40 μμc.) at which a Medical Research Council Committee thought that 'immediate consideration' should be given to the problem. It is emphasized that no evidence had been found of such a diet being consumed by anyone. The amount of strontium-90 per gm. calcium in the average diet was about 6 μμc., and, provided that the rate of deposition of the radioactive dust did not greatly increase in the future, either as a result of meteorological factors or because of further testing of nuclear devices, such a level should give no cause for anxiety.

J. M. A. TILLEY

IMMEDIATE AND LOW-LEVEL EFFECTS OF IONIZING RADIATIONS

THE biological effects of low doses of ionizing radiations, a topic of obvious interest and importance, formed one of the main themes of a symposium held in Venice, June 22–26, under the joint sponsorship of Unesco, the International Atomic Energy Agency and the Comitato Nazionale per le Ricerche Nucleari of Italy. The Organizing Committee included Prof. Z. M. Bacq (Belgium), Profs. E. Boeri and A. A. Buzzati-Traverso (Italy), and Dr. A. Hollaender (United States). Those invited were fortunate in being able to take part in a conference of which content and programme arrangements were of a high order, and which was held in the beautiful surroundings of the Fondazione Giorgio Cini, on the Isola di San Giorgio Maggiore. Each of the nine sessions was arranged to contain only a few papers, so that there was ample time for discussion and for a few short communications which were relevant to the main themes. Sixteen countries, and a wide range of scientific disciplines, were represented among the 116 research workers who took part.

The symposium opened with a review of certain aspects of quantitative radiobiology by K. G. Zimmer (Kernreaktor, Karlsruhe, Germany). After discussing critically some of the postulated mechanisms of the biological action of ionizing radiations, he went on to describe recent results obtained by the use of microwave spectroscopy This topic, discussed also by J S Kirby-Smith (Oak Ridge, United States), is of great interest because persistent magnetic centres can be observed in irradiated biological materials of low water content, and the signals are modified by environmental factors which are known also to modify the biological effects of radiation However, caution is necessary in interpreting the results obtained by instruments currently in use, since the signals observed arise from about 10^{10} times as many ionizing events as those which in many cases initiate biological damage

New techniques which have recently been developed for studying cells in mitosis have enabled investigators to undertake the difficult task of observing quantitatively the induction of chromosomal abnormalities in human cells M A Bender (Oak Ridge, United States) had examined effects on human cells in tissue culture, and also on monkey cells *in vivo*, using bone marrow The cells irradiated *in vivo* gave a somewhat lower yield of chromosome aberrations Doses down to 25 r were used in these studies

The effects of considerably lower doses on human cells were observable by M Ingram (University of Rochester, United States), who had found significant increases in the number of binucleate lymphocytes present in the blood of persons exposed to doses considered to be in the 'tolerance' range Although ionizing radiation is not the only agent which can bring this about, it was of interest that in a field investigation of uranium miners, a higher count of binucleate lymphocytes was found in the blood of the control group of coal miners, who had been subjected to regular routine diagnostic X-ray examination [1] Another paper on effects of X-irradiation on the blood picture of mammals was given by S Hajduković (Institute for Nuclear Sciences, Yugoslavia), who used as his test effect the increase in the number of reticulocytes released into peripheral blood He reported that increases were also obtained when serum from irradiated animals was injected into non-irradiated ones, the effect not being species-specific These changes were observed fairly early after the irradiation

The subject of chemical protection against biological effects of ionizing radiation was reviewed by D W van Bekkum (National Defence Research Council, Holland), who discussed different groups of protective substances and critically examined possible mechanisms of action R Brinkman (State University, Groningen, Holland) described techniques for examining the protective effect of chemicals against radiation-induced changes which could be measured very soon after low doses of irradiation These included measurements of the viscosity of synovial fluid, and of intradermal pressure Effects of irradiation could be observed within one second, and serotonin injected intradermally was the most effective of the protective substances used M Ebert and A Howard (Medical Research Council and British Empire Cancer Campaign, Great Britain) described some of their latest findings with inert gases These gases suppressed the enhancing action of oxygen when used at pressures above atmospheric, but were less effective in the cold than at room temperature J F H Maisin (University of Louvain, Belgium) had found that small doses of radiation could themselves protect against the damaging effect of larger doses Yeast cells were exposed for long periods to continuous irradiation which was not itself sufficient to kill the cells , thereafter, larger doses were required to produce a given killing effect on these than on control cells Rats which had been exposed to radiation *in utero* or as new-borns were more resistant than controls to radiation given afterwards

Various types of immediate response to irradiation had been observed by O Hug (International Atomic Energy Agency, Austria), who showed a film which demonstrated reflex reactions of snails, sea urchins and ants It was clear that an immediate effect of radiation could be observed with nerve tissue, long thought to be comparatively insensitive to its action A different type of immediate response was reported by A Forssberg (Institute of Radiophysics, Sweden), who has observed reversible effects of doses as low as 10^{-3} r on the fungus *Phycomyces blakesleeanus*, the growth-rate of the sporangiophore being immediately reduced Depression of growth-rate was accompanied by an increase in the level of acid-labile phosphorus, and a slightly delayed increase in lactic acid It was suggested that the use of adenosine triphosphate might be blocked by the radiation

Radiobiologists continue to search for the biochemical links between the absorption of ionizing energy and the manifestation of the effects observed, and various approaches were reported P Alexander (Chester Beatty Research Institute, Great Britain) gave an account of physico-chemical studies on effects of radiation on deoxyribonucleic acid *in vitro* and in herring sperm, including a discussion of the phenomenon of cross-linking K I Altman (University of Rochester, United States) had studied the breakdown of muscle collagen in rats previously fed with labelled amino-acids Whole-body irradiation with lethal doses was followed by a reduction in the hydroxylation of proline and an increase in that of its precursor

A Chevallier and S Manuel (University of Strasbourg, France) found that one result of radiation which could be measured within a short time was a drop in the ascorbic-acid content of almost all tissues, particularly the spleen While this was true of animals irradiated as a whole, spleen slices irradiated *in vitro* did not demonstrate the phenomenon, nor was it observed when only the exteriorized spleen was irradiated The authors concluded that the drop in ascorbic acid in the spleen depended on effects on other organs P Mandel and P Chambon (University of Strasbourg, France) reported studies on ribonucleic acid synthesis in rat spleen after whole-body irradiation Accumulated nucleotides were found in this organ from 12 hours after irradiation R Goutier, M Goutier-Pirotte and P Ciccarone (University of Liège, Belgium) examined an effect which occurred soon after the comparatively low dose of 150 r (whole-body) to rats Changes in the deoxyribonuclease activity of the spleen could be detected after half an hour The activity of the extracted enzyme depended critically upon the methods used in preparing the sample The authors considered that the effect was due to a change in the enzyme molecule, and not to the effect of the irradiation on enzyme distribution

H I Adler (Oak Ridge, United States) reported on observations with a variant of *Escherichia coli* which did not synthesize catalase One effect of irradiation was to sensitize the cells to the action of hydrogen peroxide Irradiated cells exposed to its action were killed, although they would otherwise have survived

Bacteria were used in two studies of the effects of low doses of radiation Marcovich (Institut du Radium, France) had examined the induction of lysogenic bacteria, and concluded that the passage of a single ionizing particle through a cell was sufficient to bring about this effect M Demerec (Carnegie Institute of Washington, United States) made use of three biochemical mutations which occurred spontaneously with very low frequency, so that the genetic effects of doses as low as 8 5 r could be assessed In all three cases, the number of mutations induced was proportional to the dose at low doses, though the doses required to produce a given frequency of mutations differed for the three mutations chosen for study

New observations on the genetic effects of ionizing radiation on mice were reported by W L Russell (Oak Ridge, United States) These have confirmed his previous report that if a dose in the range 200–600 r was delivered at 80 r /min more mutations were induced in spermatogonia than if the same dose was delivered continuously as 'chronic' irradiation at 90 r /week or less This did not apply to mutations induced in spermatozoa The genetic effect of a single dose on oocytes was greater than on spermatogonia, whereas the reverse was true of chronic irradiation L B Russell (Oak Ridge, United States) reported that chronic irradiation was less effective than an acute dose, delivered to embryos in their most sensitive stage, in bringing about still-births and neonatal deaths

Various tests of radiation damage were used by L J Cole (Naval Radiobiological Defense Laboratory, United States) in comparing effects of single exposures and 'chronic' or fractionated radiation Single doses were less effective in inducing leukæmia or shortening the life span , but the effects of chronic irradiation doses on the fertility of female mice were much lower than were single doses The effect of as little as 25 r in a single dose could be detected in weanlings The injection of bone marrow, which protected against the lethal effects of 800 r , did not protect against loss of fertility

Immunological aspects of tissue transplantation after 300 r of X-rays had been studied by P C Koller and S Doak (Chester Beatty Research Institute, Great Britain) After fifty days, the immune response of some 'chimaeras' had reverted to the host type, others had retained the immunity of the donor, and yet others gave a mixed response

This very brief account of the subjects discussed at the symposium should make it evident how wide a range of materials, and how many different approaches, are being used in attempts to clarify some of the outstanding problems in radiation biology The proceedings of the symposium are to be published as a supplement to the *International Journal of Radiation Biology* TIKVAH ALPER

NUCLEAR FORCES AND THE FEW-NUCLEON PROBLEM

MORE than 250 nuclear physicists, including about 100 delegates from fifteen countries overseas, attended the international conference, which was held at the Physics Department, University College, London, during July 8–11 A conference on the behaviour of light nuclei had not taken place for several years and was initiated by physicists at Los Alamos and University College. As was stressed by Prof H S W Massey (University College), who opened the conference, although the original intention was to emphasize the few-nucleon problem, discussion of nuclear forces had inevitably to be included

The conference consisted of five main sessions, the first and longest being entirely devoted to the primary two-nucleon interaction In this session review papers were given by Profs R E Marshak (Rochester), R Wilson (Harvard), K A Brueckner (Pennsylvania) and G F Chew (Berkeley) on both the experimental and theoretical status of the problem Interest centred on many sets of measurements, including triple scattering and correlation experiments, as well as more accurate cross-section measurements at various energies and on their interpretation in terms of the S-matrix Prof G Breit (Yale) presented an extensive search for phase-shift fits to the scattering data up to 340 MeV , while comparison was made with phase-shifts derived from various phenomenological potentials by Prof Marshak There was discussion on both the necessity and theoretical justification for including spin-orbit and other velocity-dependent potentials in the two-body force The experimental papers were concerned with recent triple scattering measurements in p–p scattering at Rochester and Harwell and with p–p angular distributions at Minnesota Also n–p angular distributions and polarization measurements from 20–120 MeV were reported by Dr J J Thresher (Harwell)

Dr J Iwadare (Kyoto) summarized the recent work done in Japan on the meson-theoretical two-nucleon interaction and its comparison with experimental data This was followed by Prof Chew's paper, which reviewed recent work on the meson field-theoretical approach to the two-body problem starting from the Mandelstam conjecture on the analytical form of the scattering amplitude The inclusion of the pion–pion interaction within the context of dispersion relations seems to be the next step in the long struggle to obtain meaningful results from the meson theory of nuclear forces proposed by Yukawa in 1935

Prof Yukawa was chairman for the beginning of the second session, on the scattering of nucleons by light nuclei at high energy A review paper on the impulse approximation by Dr H McManus (Chalk River) was followed by applications of this approach to the n–d and p–d case by Drs L Castillejo (Birmingham), R Phillips (Harwell) and by Japanese workers The problem was examined from the point of view of dispersion theory in a paper by Goldberger, Halpern and Blankenbecler (Princeton), and corrections due to multiple scattering were considered by Prof R J Glanber (Harvard) In this session there were reports by Drs A M Cormack, T C Griffith and G Huxtable on experiments done at Harvard, University College and Harwell respectively on p–d and p–α scattering at energies between 50 and 150 MeV

The session on photonuclear reactions with light nuclei opened with a review by Dr D Dixon

(Glasgow). Other papers were presented by Profs. G. Breit, A. Klein (Pennsylvania) and Dr. Iwadare. The effect on the theory of the photodisintegration of the deuteron of the spin-orbit force within the n–p system stimulated much discussion.

The fourth session of the conference was devoted to the question of binding energies and elastic scattering of light nuclei at low energies. The review papers were given by Prof. H. S. W. Massey and Dr. P. G. Burke (University of London) on the three-body problem and on the elastic scattering of nucleons by alpha-particles. There were also two invited papers from Los Alamos. Dr. L. Cranberg reported on experimental results concerning total and differential cross-sections and also polarization measurements in the scattering of low-energy neutrons from ^{2}D, ^{3}H and ^{3}He, while Dr. L. Rosen reported on charged particle scattering from ^{2}D and ^{3}H at energies up to about 20 MeV. These experiments led to several new checks on charge symmetry and time reversal invariance.

The contributed papers included one on the ground-state energy of the triton, by Prof. J. M. Blatt (Sydney). Using the Gammel–Thaler potential, no bound state was found for reasonable trial wave functions. Among other papers from Los Alamos, Dr. J. L. Gammel gave a preliminary account of attempts to integrate the n–d problem numerically and discussed the feasibility of spin-correlation experiments using ^{4}He as an analyser.

Polarization measurements in n–d and p–d scattering at low energies, reported by Dr. H.-J. Gerber (Zurich) and Dr. R. E. Segel (North-western University), indicate that there is very little polarization at about 4 MeV. A contribution from Dr. N. Vlassov (Moscow), read by Dr. I. A. Baz, on the interaction of protons and deuterons with light nuclei ended this session.

The last session, with a title "Reactions Involving Four or More than Four Nucleons", was opened by Dr. B. H. Bransden (Glasgow) with his paper on the collisions of neutrons and of deuterons with ^{3}H and ^{3}He. This paper was followed by a number of papers involving the application of the resonating group structure method to binding energy and scattering calculations. This method, as did the impulse-approximation method at higher energies in a previous session, aroused considerable controversy during the discussion. Nevertheless, it was felt that some progress had been made, since one type of mixture of exchange forces does seem to be simulating the exact force in more than one situation involving light nuclei.

Prof. G. Skornyakov (Moscow) then gave his paper on n–d scattering in the zero-range force approximation, this being a contribution to the previous session. The three-particle problem is solved accurately in this limit. He also read a paper by Dr. T. Y. Barit on p–T scattering and allied reactions.

The final papers were preceded by a review given by Dr. V. J. Emery (Harwell) of the calculations of the binding energies of nuclei using the Brueckner method. Prof. Brueckner himself also presented a paper on the Hartree–Fock method for strongly interacting systems. The conference concluded with papers by Profs. N. Austern and S. Meshkov (Pittsburgh) on preliminary calculations concerning the structure of ^{6}Li and ^{12}C.

CHAGAS'S DISEASE

CHAGAS'S disease or South American trypanosomiasis, occurring chiefly in Brazil and other countries of South America, is caused by *Trypanosoma cruzi* and is spread mainly by reduviid bugs. The disease was first discovered and described fully in 1909 from the State of Minas Geraes in Brazil. All the significant observations regarding the causative agent, the vector, mode of transmission and symptoms were made then, by that creative genius, Carlos Chagas. In order to commemorate the fiftieth anniversary of this discovery, an international congress on Chagas's disease was held at Rio de Janeiro during July 5–11.

Foreign delegates from European countries, Israel and the United States of America numbered more than seventy. Approximately 300 others from Brazil and the neighbouring countries of South America also attended. At a short historical session at the Ministry of Education and Culture on July 4 the life and work and significance of the discoveries made by Chagas were described by various speakers.

The inaugural meeting of the congress was held on July 5 in the National Faculty of Medicine from 9 p.m. until midnight, when addresses were delivered by Prof. Alessandri (Chile), Prof. Lemoigne (Pasteur Institute, Paris), Dr. Candau (director general, World Health Organization), a student in the Medical Faculty, Prof. Moraes, director of the Medical School and dean of the University, and replied to by Prof. Carlos Chagas Filho.

The real business of the congress began on the following morning at 9 a.m. and lasted until 6 p.m. in a pavilion within the grounds of the Instituto Oswaldo Cruz. Two or three sessions took place concurrently to discuss the disease in its different aspects. In one of the lecture theatres simultaneous translations from English, French, Spanish, Portuguese and German were provided. Chagas's disease in the American continent was discussed from the pathological aspect and the different forms encountered in the various South American countries described, including the clinical findings on the two human cases thus far reported from the southern United States. Other papers on transmitting agents, animal reservoirs, including the opossum and armadillo, and their relation to the epidemiology of the disease as well as the characters of the human strains, were discussed. Public health questions were reviewed in relation to the geographical distribution of the principal transmitters of the disease which infest human dwellings. The anatomy and respiratory system of *Triatoma infestans*, the chief vector in Brazil, was described. On the following day the subject discussed in one section was the ætiological agent, with emphasis on the physiology, metabolism and nutrition of the parasite. Electron microscope studies of parasitized cells were included. In another section immunological aspects of the disease, including complement fixation reactions, precipitin and skin tests, were dealt with and the isolation of immune polysaccharides from the organism described. The occurrence of toxins in cultures of the organism appeared to be doubtful. The epidemiology of the disease was discussed in seven papers. Polymorphism which occurs in African trypanosomes was compared with that met with in *T. cruzi*, and observations made on the nature of their evolutionary cycles. The session was concluded by the showing of a film dealing with methods of eradication of the tsetse fly, which transmits the disease in Portuguese Africa. On the same evening a meeting was held in the Brazilian Academy of Sciences from 9 p.m. until midnight, at which a paper was read on "Chagas as Protozoologist", and others on the metabolism, phylogeny and growth of the parasite. The following day was devoted to the pathology of acute and chronic cases of the disease in different parts of the South American continent, throughout which the virulence of the causative agent varies. Discussions took place on the myocardial, nervous, cerebrovascular and blood protein changes involved, as well as on the condition of megacolon and megaœsophagus now believed to be causally related to the disease. Further papers on epidemiology dealt with animal reservoirs and with the feeding habits of domestic and wild types of reduviid bugs. The danger of blood transfusion as a means of spread was also dealt with. Prophylaxis was best effected by spraying the sites where the vector was found, along with general hygienic measures. Workers from different areas of South America, where the nature of the problem varies with the transmitting agent, contributed also on the following day. The different clinical forms and diagnosis of the disease, including that met with in congenital cases, were described in seven papers. At a special session the nature of the infection caused by *Trypanosoma rangeli* was described. This parasite was first described in 1920 by Tejera in Venezuela, where it infects *Rhodnius prolixus*, which is also the chief transmitter of *T. cruzi* there. The first forms were seen in human blood in Guatemala in 1946, and now 795 cases of infection have been described in Venezuela, chiefly in children, but the infection is not of serious character. At an evening session in the National Academy of Medicine further papers were read. On the last full working day of the congress, eighteen papers were read, chiefly on the relationship of cardiac and nervous disorders, including megacolon and megaœsophagus, to Chagas's disease. Discussions also took place on chemotherapeutic agents, but the sad fact remains that no curative agent is known for this disease. A short ceremony took place during the morning at which a plaque, presented by the Argentinian delegation, to the memory of Carlos Chagas was unveiled.

On the same day a paper was read by Prof. Jean Coudert on the action of *T. cruzi* extracts on cancer cells, another by William Frye on antibiotics in tropical disease, and Rene Dubos gave a talk on general aspects of infection.

The final meeting on July 11 was devoted to round-table discussion of the subjects dealt with earlier in the week. Resolutions were also submitted regarding the holding of another international congress within the next few years, but no definite decisions were arrived at. During the week more than 150 papers were read. Two medals were struck to commemorate the congress, each with the head of Carlos Chagas on one side, but differing on the obverse side. The proceedings of this inspiring congress will be published in due course.

SPECIAL CERAMICS

The challenge of temperature, which has inspired the metallurgist to some of his more notable developments, has in recent years been renewed and has been taken up by the ceramist, who is seeking materials of low creep resistance, high thermal shock resistance and high hot-strength to meet the demands of propulsion engineering, high-speed vehicles and nuclear engineering. The ceramist has for many years made his own special contribution to communications engineering, chiefly in the exploitation of oxide-type materials; the field of non-oxide materials remained largely unexplored, but it is now being opened up by the drive for new materials in other engineering applications. The British Ceramic Research Association has for the past five years had a small group devoted to these studies and has been working in close co-operation with various Service departments and industrial concerns. It was felt that some attempt to set up a forum for the exchange of ideas would be timely, and the outcome was a Symposium on Special Ceramics held at the Laboratories of the British Ceramic Research Association in Stoke-on-Trent during July 13–15. About 150 delegates attended the symposium and seven countries were represented. The subject-matter of the symposium was divided into four sessions dealing with (1) properties and structure, measurements; (2) preparation and properties of nitrides; (3) preparation and properties of other non-oxides; and (4) furnaces, techniques, analysis, applications, etc.

After a welcome to the delegates by the chairman of the Association, Mr. E. James Johnson, and the director, Dr. A. T. Green, the deputy director, Dr. N. F. Astbury, gave an introductory lecture on the fields of application for new ceramic materials, and spoke of the special ceramics research programme of the British Ceramic Research Association, in which particular reference was made to boron nitride, a machinable dielectric capable of withstanding high temperatures, and to a new form of self-bonded silicon carbide and to silicon nitride. Both the latter materials are being actively studied in connexion with rocket engineering. The dependence of macroscopic properties on crystal structure and the trends observed in groups of materials of the same structure were discussed in a paper by Dr. S. N. Ruddlesden (British Ceramic Research Association), who illustrated her arguments by non-oxides such as silicon nitride and boron phosphide, the latter being a new compound of the III–V series of zinc-blende structures. Like silicon carbide, boron phosphide is very hard and it is a semiconductor with an energy gap of the order of 5 eV.

The greatest challenge that ceramics must face in meeting metals in their chosen field is the absence of ductility and their comparatively low breaking strain. The reply to this is being sought by a study of the properties of certain oxide crystals, and it was of special interest, therefore, that Dr. F. J. P. Clarke (U.K. Atomic Energy Authority, Harwell) was able to give an account of his experiments on the room-temperature ductility of single crystals of magnesium oxide, together with his observation of slip bands and fracture starting at the intersection of these slip bands near a crystal face Dr Clarke discussed possible applications of his results to polycrystalline materials

Methods of measuring thermal conductivity requiring much less time than traditional methods were described by Mr T W Lindop (Morgan Crucible Co), and Mr R P Tye (National Physical Laboratory) contributed to the discussion with an account of an even more rapid (< 1 min) comparator method A simple apparatus for the measurement of creep at high temperature (1,200° C) was described in a paper by Messrs N L Parr and G F Martin, read by Mr D M Rae (Admiralty Materials Laboratory) Dr Clarke ended the first session with a description of the effect of reactor irradiation on ceramic materials, which aroused some lively discussion on the damage mechanism and the neutron energies causing most damage.

Silicon nitride is a hard, very strong material (the modulus of rupture at 1,200° C is of the order of 18,000 lb /sq in) which can be made into shapes of accurate dimensions by nitriding pressed silicon-powder, since no contraction occurs during the firing Its preparation, its properties as an engineering material (it possesses very good thermal shock resistance and satisfactory resistance to creep) and its microstructure were described by Messrs N L Parr, G F. Martin and E R W May (Admiralty Materials Laboratory) In the subsequent discussion, Mr P Popper (British Ceramic Research Association) showed photographs of some intriguing spiral 'whiskers' of silicon nitride A new hexagonal form of Be_3N_2 was described by Drs A Rabenau and P Eckerlin (Philips, Aachen), who had studied the system Be_3N_2—Si_3N_4 and found two other compounds, Be_4SiN_4 and a wurtzite-type compound, $BeSiN_2$

There is a wide gap between organic plastic insulators, which can be easily shaped by moulding or machining but which cannot withstand high temperatures, and refractory insulators, which can withstand very high temperatures but are difficult to make to accurate dimensional tolerances One material which helps to bridge this gap is boron nitride, a refractory insulator which can be easily machined, a property which is attributed to its layer lattice crystal structure, which resembles that of graphite, with which it is isosteric It is not wetted by many molten metals and has a high electrical resistivity (10^6 ohm cm at 1,300° C) and high resistance to chemical attack The preparation of boron nitride, its possible uses, the control of hot-pressing and stability by additions of 'impurities' were described by Dr T A Ingles and Mr Popper (British Ceramic Research Association) Other possible materials to bridge the gap are being sought in polymers which contain boron and nitrogen or phosphorus and nitrogen The paper by Messrs F W Ainger and I M Herbert (Plessey Research Laboratories) on the preparation of phosphorus–nitrogen compounds as non-porous solids was remarkable for the presentation of so much inorganic chemistry in the language of the organic chemist

Knowledge of dissociation pressures is important in considering materials for high-temperature applications, and measurements of the dissociation pressures of metallic silicides and of silicon carbide were reported by Mr P Grieveson and Dr C B. Alcock (Imperial College of Science and Technology), who interpreted their results on a thermodynamic basis A novel way of preparing an extremely strong, dense silicon carbide, without the need for hot-pressing, was described by Mr P Popper The method involves heating a cold-pressed mixture of carbon and silicon carbide powder in an atmosphere of silicon vapour when, under appropriate conditions, a material is obtained with a density of 3 05 gm /cm ^{3} (corresponding to 95 per cent crystallographic density) and a modulus of rupture at room temperature of the order of 30,000 lb /sq in Another silicide, $MoSi_2$, described by Mr J B Huffadine (Plessey Research Laboratories), has a very low electrical resistivity and is used in heating elements It has a remarkably high oxidation resistance and an expansion coefficient substantially the same as alumina, from 0° to 1,000° C It also adheres strongly to alumina if hot-pressed with this oxide, and it was suggested that composite $MoSi_2$—Al_2O_3 pressings could provide useful electrical components

The preparation and properties of calcium fluoride ware were described by Mr P Rado (Worcester Royal Porcelain Co) Although this material has a very poor thermal shock resistance, it has found application as a crucible material for the reduction of metallic fluorides, particularly uranium fluoride

Photoconductive materials have normally been used in the form of single crystals, but Drs W van Gool and J G van Santen (Philips, Eindhoven) showed that a polycrystalline aggregate of cadmium sulphide could be used as an element in photosensitive devices

Throughout the symposium attention was repeatedly directed to the high-temperature techniques required in the preparation of special ceramics, and some of these were discussed in detail in the final session, which included three papers on furnace design Dr A Z Borucka (Metals Research, Ltd) described the construction of a furnace to give a hot zone (1,200° C) of very uniform temperature by having the furnace windings split into several sections with the spacing of the windings graduated in each section Dr M Cole and Dr Borucka (Metals Research, Ltd) described a novel replaceable heating element, consisting of a molybdenum heater encased in an alumina sheath through which hydrogen or another protective gas is passed These elements can heat a furnace with a capacity of several cubic feet to 1,800° C in either oxidizing or reducing atmospheres, giving a uniform temperature distribution with no contamination of the furnace atmosphere The construction and advantage of various types of carbon-tube furnace, that is to say, the simple tube, the single-ended, hairpin-cut tube and the spiral-cut tube, capable of operating at temperatures above 2,000° C *in vacuo* or in controlled atmospheres, were described by Mr C J W Baker (British Ceramic Research Association)

Many of the special ceramic materials cannot be melted under normal conditions, and so sintering cannot be used as a means of densification The alternative technique is hot-pressing, but this has the disadvantage in general that only simple shapes can be produced without further machining Dr J S Jackson and Mr P F Palmer (British Thomson-Houston Research Laboratories) described an apparatus designed for hot-pressing small specimens of refractory hard materials to high density in graphite dies heated by passing a high current through the walls They reported the contraction of various carbides, borides and oxides as a function of temperature, and showed that reduction of particle size reduced the temperature needed for densification

One of the difficulties of powder aggregation is the variation in density which may occur through the compact This difficulty can be circumvented by isostatic pressing, and the use of a reversible gel, such as a polyvinyl polymer, as a mould material giving substantially true hydrostatic pressures up to 50 tons/in ^{2} was described by Mr T W Penrice (Production Tool Alloy Co) The technique is evidently applicable to quite complicated shapes

The analyst's outlook on the new materials was touched upon in a paper by Mr H Bennett (British Ceramic Research Association) on the chemical determination of nitrogen in refractory nitrides, which posed many new problems The final paper was a description by J Peyssou (C S F, France) of the possible variations of properties of ceramic articles caused by variations in firing conditions and methods of manufacture

The symposium concluded with a tour of the laboratories of the British Ceramic Research Association The proceedings of the symposium are to be published by Heywood and Co as a book, "Special Ceramics", which is being edited by Mr P Popper

N F ASTBURY

SOLID STATE PHYSICS

A CONFERENCE was held at Melbourne on "Solid State Physics" during August 17–21 under the auspices of the Australian Branch of the Institute of Physics Grants from Australian industry, learned societies, government organizations and universities and support by the United States Government research authorities, the United Kingdom Atomic Energy Authority and the Canadian Government enabled several Americans, a Canadian and three Englishmen to attend Other States of the Commonwealth of Australia and New Zealand were well represented

The matter was drawn from across almost the whole range of this enormous subject, and one could hope that it might set a style of conference where the programme would be not so specialized that only a few experts could really benefit

The programme opened with a day devoted to low-temperature properties of metals and alloys Precision lattice parameters, superconductivity and superfluidity, dislocation-phonon scattering and electron phonon drag effects were discussed The changes of lattice parameter in bismuth on alloying set a challenge to the theorists, and the dislocation scattering of phonons seems still to be in error by a factor assessed as between three and seventy by one speaker

Electron field emission, low-energy sputtering, epitaxial growth and dislocation barriers at surfaces served during the next day to remind those present just how little of the surfaces of solids is understood The afternoon and following day were devoted to plasticity studies, when softening by adiabatic heating was used to explain the serrated load extension curves of iron at temperatures immediately above the brittle fracture region, as well as for aluminium at very low temperature The dependence on orientation of work hardening and of slip-system geography in face-centred cubic metals were presented, and it was clearly the opinion of the majority that current theories are far too simple in their outlook The Peierls–Nabarro force, its connexion with lattice friction, and the significance of the friction term in the hardening curves formed a recurrent theme in and out of the lecture room Preliminary results indicate that reliable twin-fault densities may be obtained from the asymmetry of Bragg peaks and this may inject a little more knowledge of the deformed state Measurements of the mechanical properties of the alkali metals at very low temperatures, along with optical microscope studies, have confirmed the X-ray evidence of shear transformations in sodium and lithium, and have brought to light a great sensitivity to structural details in the transformation of the crystalline aggregate

On the third day attention was swung to optical properties of solids, with papers on soft X-ray studies of the light metals, infra-red and optical absorption in ionic crystals Dielectric properties of doped alkali halides, evidence for aggregation of *F* centres and new techniques and facts in luminescence studies were the subjects for the remainder of the day The analysis of rare-earth spectra in crystals is getting steadily more detailed and very large-scale calculations are rapidly elucidating the details of interactions within the *f* electron-shell

The last day saw an interesting mixture of papers the dreadful maze into which theoretical physicists lead each other when the anharmonic terms leading to thermal expansion are studied was on show, as was the theory of zone structure in liquids Here some progress seemed to be made for the one-dimensional model The magnetic structure of metallic chromium and its alloys was discussed in terms of magnetic properties and neutron diffraction evidence Then came the grand finale with one situation well on the way to elucidation and three well on the way to confusion The ordering of α-brass at temperatures of about 135° C has been most convincingly shown and will probably remove the few remaining anomalies in the properties of the αCu—Zn phase in this temperature region But in copper the first annealing observed after very low-temperature bombardment now occurs at only 7° K, and the atomic processes involved get steadily more mysterious Polycrystalline calcite or 'marble' plastically uni-axially compressed at high hydrostatic pressure, largely recovers its axial dimensions on release of the hydrostatic pressure In lithium fluoride as well as silicon iron, plastic hardening seems to denote a drop in dislocation speed under a given stress, indicating an increase in dislocation viscosity—or is it a drop in effective stress ?

It was a stimulating conference, and those from overseas were impressed to find such a wealth of first-class work, enthusiasm and hospitality in this rapidly growing and developing continent of Australia.

W M LOMER

UNIVERSITY GRANTS IN GREAT BRITAIN

THE annual returns from universities and colleges in receipt of Treasury grants from the academic year 1957–58, now covering twenty-one universities and three colleges, issued by the University Grants Committee, records a further increase in the number of full-time students to 95,442, compared with 89,866 in 1956–57 (Pp 54 Cmnd 832 London H M Stationery Office, 1959 5*s* net) Statistics collected in October 1958 showed a university population of about 100,000, and this number is expected to reach at least 110,000 by 1961–62 There were 6,180 full-time and 2,208 part-time students from overseas within the British Commonwealth and 3,982 full-time and 1,904 part-time students from foreign countries, for 1956–57 the corresponding figures were 6,115 and 2,016 for the Commonwealth and 3,792 and 1,756 for foreign countries Of full-time new students 36 4 per cent were in arts, 23 7 per cent in pure science, 19 0 per cent in technology and 13 7 per cent in medicine these figures compare with 38 7, 15 2, 13 5 and 26 1, respectively, in 1938–39 For full-time women students the corresponding figures for 1957–58 are 63 5, 20 0, 0 8 and 12 1, respectively, and for 1938–39, 64 7, 15 9, 0 8 and 16 2 Full-time advanced students of pure science numbered 3,853 (34 8 per cent), of technology, 1,916 (17 3 per cent), and of medicine, 968 (8 8 per cent), 3,007 students were taking postgraduate courses in teacher training

Of the full-time students 76,687 were reading for a first degree, 3,937 for a first diploma and 14,069 engaged in research or other advanced work, the corresponding figures for 1956–57 being 71,713, 3,969 and 13,379, respectively Of the new full-time students, 24 0 per cent were in pure science, 15 4 per cent in technology and 9 3 per cent in medicine, for 1956–57 the corresponding figures were 23 8, 15 0 and 9 6 per cent, respectively

The proportion of assisted students was 79 2 per cent compared with 75 7 per cent in 1956–57 and 71 9 per cent in 1953–54, ranging from 92 2 per cent in Wales, 86 7 per cent in English universities, excluding Oxford, Cambridge and London, to 67 2 per cent for Scotland Full-time teaching and research staff increased to 10,542, compared with 10,485 in 1956–57 The proportion of full-time students residing in colleges or halls of residence was 26 4 per cent compared with 27 4 per cent in 1956–57 although the total, 25,174, was higher The proportion of men in residence, excluding Oxford, Cambridge and London, was 22 4 per cent and of women, 38 6 per cent, whereas 46,237 (48 4 per cent) were in lodgings and 24,031 (25 2 per cent) at home, compared with 46 per cent and 26 6 per cent, respectively, the previous year

Of the recurrent income of £49,418,302 (an increase of £7,762,693 on 1956–57) £34,953,406 was from Parliamentary grants (70 7 per cent) Income from fees increased from 11 2 per cent to 11 5 per cent, local authority grants decreased from 3 1 to 2 8 per cent, endowments from 4 0 per cent to 3 6 per cent, donations and subscriptions from 1 2 to 1 1 per cent, and payments for research (£3,008,898) from 6 5 per cent to 6 1 per cent Non-recurrent grants in respect of capital expenditure amounted to £11,816,479 compared with £9,134,185 in 1956–57 and of the recurrent expenditure of £48,335,053—an increase of £6,825,350 on 1956–57—7 1 per cent was spent on administration, 68 6 per cent on departmental maintenance and 12 5 per cent on maintenance of premises Expenditure on libraries increased from £1,620,958 to £1,821,943 but decreased to 3 8 per cent of the total

NUCLEAR RESEARCH IN AUSTRALIA

IN the sixth annual report of the Australian Atomic Energy Commission (Commonwealth of Australia, 1958 Pp 62 Sydney Australian Atomic Energy Commission, 1959), covering the year ended June 30, 1958, considerable space is devoted to the Commission's Research Establishment at Lucas Heights, which was officially opened by the Prime Minister of Australia, the Rt Hon R G Menzies, on April 18, 1958 During the period up to the beginning of May approximately 4,500 visitors went to the Establishment Many of the major buildings have been completed and this has enabled the research staff to return from Harwell and to begin to design and assemble equipment for their research projects The Commonwealth Government has approved a further building programme involving an expenditure of £1 6 million during 1958–59 and 1959–60 on new laboratories and services, including engineering research laboratories, a building in which the fabrication and chemistry of beryllium fuels can be studied, and post-irradiation handling equipment

The report details the work of the principal sections of the Establishment and the various research projects to be undertaken The main function of the Isotopes Section is the advisory service to industry and research, and 310 requests for advice on various aspects of isotope production were dealt with during the year Australian industry and research in comparison with the United States of America or the United Kingdom has, however, been slow to accept the use of radioisotopes The Section assisted in a large-scale field test, in which a radioisotope technique was used to measure the efficiency of mixing in a cooling pond in an electrical power station Other investigations included the development of a method for the continuous investigation of moisture content of brown coal, a technique for tracing sewage sludge in sea disposal, siltation in the Hunter River, and the use of radioisotope tracers in cloud physics

A large proportion of the work of the Technical Physics Section has been concerned with the installation and commissioning of the control gear and instrumentation of the High-Flux Australian Reactor, at the Establishment Other equipment constructed and tested include a fast scaler, using transistors, with 'plug-in' scales of ten, and a discriminator with resolving time of 1 μsec, a beta-gamma coincidence unit, and linear amplifiers and scintillation counters for the Health Physics Section.

One of the aims of the fuel element research conducted at the Establishment is to develop a 'self-breeding' fuel in which thorium is present in such quantities that fissioned uranium is continuously replaced by uranium-235. Beryllium and beryllium oxide are also being studied as moderator materials and fuel carriers. Another problem under study is the production of graphite which is impermeable to fission product gases and several methods of sealing inherent porosity are being investigated. Research on a sodium-based liquid metal fuel reactor was begun at Harwell and is being continued at Lucas Heights. The experimental assemblies built by the Australian staff while at Harwell have been purchased and shipped to Australia. The sodium plant built by the Australian Atomic Energy Commission at the Research Establishment is a research tool designed to pump molten sodium at 500° C at 10 gall. per min. and it will provide facilities for carrying out research on compatibility problems, sodium component testing, heat-transfer investigations and the training of staff in the handling of liquid metals.

In the sections of the report dealing with the search for, and mining of, uranium details are given of the airborne radiometric and geological surveys carried out by the Bureau of Mineral Resources. There was a marked decline in interest in the search for uranium both by companies and individual prospectors. This is attributed to the uncertainty regarding the future of the world uranium market. The picture presented in the report is that of a rather difficult period in the years immediately ahead, but that the present rate of production could well prove insufficient within the next decade. The production of uranium oxide at Rum Jungle was lower than in the preceding year. Full-scale open-cut mining has been in progress at Mary Kathleen during the year and a large stock-pile of ore for treatment has been built up. A recalculation of the ore reserves of the Mary Kathleen deposit has shown that the total reserves of recoverable uranium oxide are greater than was originally thought and more than enough to complete the contract with the United Kingdom Atomic Energy Authority.

A symposium on the "Peaceful Uses of Atomic Energy in Australia" was held in Sydney during June at which 114 papers were presented. Brief details of the proceedings are given in the annual report, and a record of the papers and discussions is to be published. The publication of a new quarterly, *Atomic Energy*, giving information on developments in and applications of nuclear science and technology was commenced during the year, and the booklet entitled "Prospecting and Mining for Uranium in Australia" was reprinted. Six atomic energy exhibitions in various towns in the Commonwealth were presented by the Commission in addition to several television programmes at national and commercial stations in Sydney. The annual report concludes with a statement of the net expenditure of the Commission for the year ended June 30, 1958, details of the extra-mural research projects at various Australian universities, the names of the senior research staff and holders of the postgraduate research studentships and undergraduate scholarships, and a bibliography of the principal publications of members of the Commission, its staff and advisory committees.

CONSERVATION OF ENGLISH WALLPAINTINGS

In recent years those interested in early wallpaintings have been greatly perturbed by their condition and the rather haphazard methods sometimes employed for their preservation. It was therefore more than timely in 1953 for the Central Council for the Care of Churches and the Society for the Protection of Ancient Buildings to appoint a committee to report on the nature and causes of the troubles which have been observed in such paintings, the remedies which could be applied and the methods which would give the best hope of successful preservative treatment in the future. The report[*] was compiled under the able chairmanship of Mr. W. I. Croome. The committee included well-known archæologists and scientists who had made a special study of this problem.

At the outset the committee was seriously perturbed by the use of varnish and wax as a preservative, for these act as relatively impervious skins and impede the rate of evaporation of moisture and cause disintegration of the surface. As a preliminary measure it advised that these two methods should cease immediately.

The report continues with an instructive and necessary explanation of the technical terms and materials used in wallpainting. Then follows a useful summary of English and foreign practice in relation to wallpaintings with some pregnant notes on the effect of time. These clearly show that the conservation methods used were not satisfactory.

It was therefore abundantly clear that much fundamental work was necessary and the constructive recommendations of the committee are based on the practical applications of its conclusions.

The main recommendations deprecate the use of wax varnish, sodium silicate, or ethyl silicate for any preservative treatment. The use of caesin in a maximum 2 per cent solution in appropriate cases should be confined to the binding of loose pigment. Lime water should be used for the consolidation of the plaster foundation, and in the case of disintegration of the paint it may be mixed with skim milk. The committee stresses that since wallpaintings are liable to deteriorate under conditions of damp every care should be taken to make the church structurally sound and thus exclude any excessive moisture.

The committee feels that much further research should be undertaken on this problem and suggests a course of training which will eventually provide a succession of practitioners for this important work.

The report concludes with some practical notes for the removal of wax preparations, retouching and overpainting, recording and some excellent illustrations of work that has already been undertaken.

---

KELLOGG AND NEY'S MODEL OF THE SOLAR CORONA

In an article in a recent issue of *Nature*[1], Profs P J Kellogg and E P Ney advance an entirely new theory of the solar corona The generally accepted explanation of the observed corona supposes that two components contribute to its light a K component due to Thomson scattering of sunlight by free electrons, which is the 'true' solar corona, and an F component due to diffraction scattering by dust lying between the Sun and the Earth The F component increases relative to the K component with increasing angular distance from the Sun The new theory suggests that the corona is an assembly of charged particles trapped by the Sun's magnetic field, analogous to the Van Allen belt of particles surrounding the Earth The contribution of the F component is regarded as much smaller than is currently supposed, and the continuous spectrum of the corona is thought to arise from synchrotron radiation as well as from Thomson scattering The authors suggest that the existing observations of the corona can be at least as well described by their model as by that currently accepted

Although the corona certainly shows puzzling features which are but imperfectly understood, the generally accepted physical description of the observed corona is less open to objection than Kellogg and Ney suppose This does not, however, rule out the possibility of an alternative explanation such as the one they propose We think it unfortunate that Kellogg and Ney have not compared the requirements of their theory with the most recent and reliable observations They seem not to appreciate the care that is now taken in eclipse work to avoid errors which are known to exist in earlier observations, and have adopted uncritically those earlier observations that they have considered In this communication we wish particularly to show that the agreement of the new theory with observation is not as good as its authors represent, rather than to criticize their theoretical reasoning

We have space to discuss only a few of the points made by Kellogg and Ney which seem to us especially open to objection For convenience these are taken in the order given in the original article

Scale height of the corona The model developed by Kellogg and Ney is suggested by the supposed similarity between the gradient of electron density in the corona (as calculated by these authors) and the gradient in the outer parts of the Van Allen belt The electron density in the solar corona has been the subject of many careful investigations, and in modern models of the corona it is supposed that, at angular distances of the order of $5R_{\odot}$ from the centre of the Sun, electron scattering contributes only about 15 per cent to the brightness However, for the purposes of their theory, Kellogg and Ney calculate the electron density assuming that *all* the light of the corona is due to electron scattering even out to $10R_{\odot}$ In their calculation they use a crude law ($1/R^6$) for the variation in brightness with distance from the Sun, an approximate method for conversion to electron densities, and then plot the results incorrectly in their diagram (According to their approximation, the electron density should vary with the linear distance $r_{\odot}$ from the Sun as r^{-5} the curve shown in their Fig 1 shows the variation as r^{-6}) Although we shall show later that we believe it wrong to neglect the contribution of the F corona out to $10R_{\odot}$, we assume for the present with Kellogg and Ney that this is permissible Baumbach's formula[2] for the brightness distribution fits the more modern observations (for example, those of Michard[3] and von Kluber[4]) within 10 per cent As Baumbach was not aware of the existence of the F component, we may also adopt Baumbach's electron densities, which assume a pure electron corona, and these are plotted in our Fig 1 together with the curve from Kellogg and Ney's diagram

Comparing the two, we see that at $10r_{\odot}$ from the Sun, and assuming electron scattering only, Kellogg and Ney have made a total error in electron density of a factor of ×350 The similarity between the Kellogg and Ney distribution and the Van Allen distribution is now almost entirely lost

In the latter half of their article Kellogg and Ney remark that there are at least three outstanding effects which are usually ignored in explaining the solar corona, these being the degree and direction of polarization, the infra-red excess, and the variation

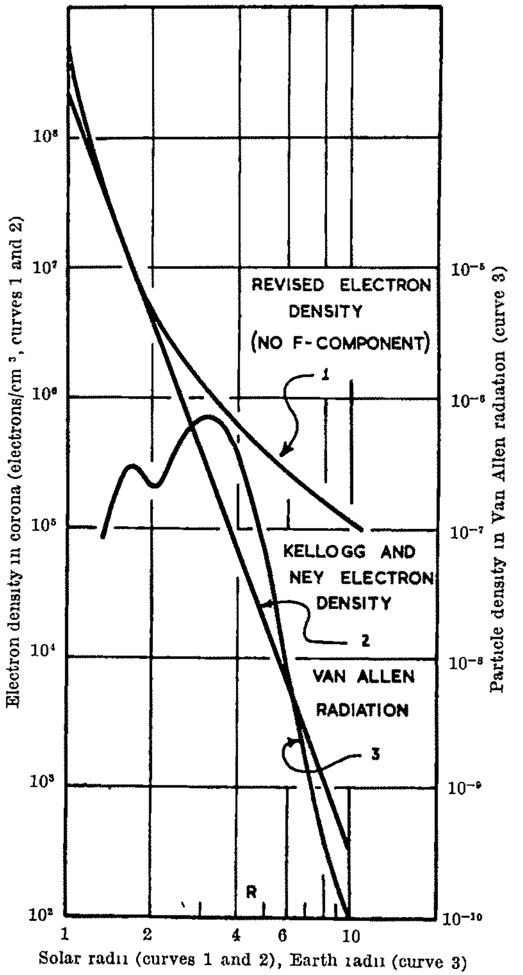

Fig 1 Plot of electron densities in the corona as calculated by Kellogg and Ney (curve 2) and revised by the present authors (curve 1) on the assumption of pure electron scattering, together with the particle densities in the Van Allen radiation (cf Fig 1 of ref 1)

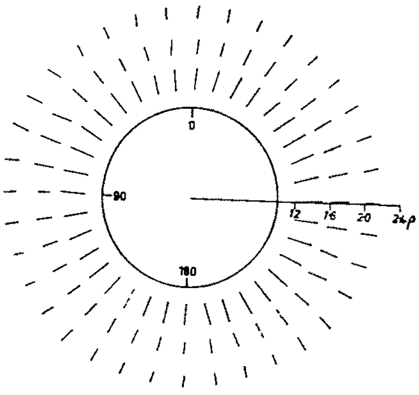

Fig 2 Direction of polarization (magnetic vector) of the coronal light observed by von Kluber at the 1952 eclipse (ref 4)

with phase in the sunspot cycle This statement is not correct, at least the first two of the effects mentioned are an important part of the conventional theory

Polarization of the coronal light Kellogg and Ney's second argument concerns the direction of the plane of polarization of the coronal light If the coronal light is merely sunlight which has been scattered by electrons or dust, or both, it must be partially polarized with the magnetic vector lying in a radial direction If, on the other hand, part at least of the light is synchrotron radiation, deviations from the radial direction would be expected which would depend upon the variation of strength and direction of the magnetic field along the line of sight As the authors remark, the measurement of direction of polarization is a very important one At the same time it is a very difficult one, and it is only in the last decade that the nature of the difficulties has been understood The sky background is strongly polarized, and except near the solar limb has an intensity comparable with that of the corona Most of the early observations of polarization were inadequately corrected for the sky background, even if the photometric procedures were adequate in the first instance, and should therefore be rejected The first author to correct for the polarization of the sky background was Öhman[5], who concluded from a careful analysis of his observations of the 1945 eclipse that the polarization of the corona at 5000 A was radial at all points examined Reliable measurements were also made by von Kluber[4] at a wave-length of 4300 A during the 1952 eclipse, his results are shown in Fig 2

Von Kluber considers that almost all deviations from the radial direction may be attributed to observational error

We now consider briefly the older observations quoted by Kellogg and Ney Zakharin's observations gave deviations of up to 80°, but Zakharin admits that the plates seem to be of very poor quality[6] Richtmeyer and Schmidt found an average deviation in three streamers of 9° and a maximum deviation of 17°, the original plates taken by Richtmeyer are of "moderate photometric quality" with irregular plate fog[7] Saito's results[8], not available to Kellogg and Ney, relate to the inner corona (there are only a few measurements beyond 6′), the deviations from radial polarization are all less than 15° and 80 per cent of the measured deviations are less than 7° It is worth commenting that the method usually used to determine the plane of polarization, namely, comparison of three simultaneous photographs, can easily lead to considerable error, especially in parts of the corona where there are large brightness gradients Summarizing, the best recent measurements do not support the large departures from radial polarization indicated by the two diagrams of Kellogg and Ney's paper

The degree of polarization is not considered by Kellogg and Ney For Thomson scattering the polarization can be computed once the distribution of electron density is known However, the computed electron density depends upon whether we assume that all the light is due to electron scattering, or whether part of it is due to either dust scattering or synchrotron radiation We therefore give in Fig 3 two curves showing the computed polarization of the electron component only Curve *A* is taken from von Kluber's work and is computed from the electron densities appropriate to a conventional model, curve *B* is taken from Baumbach's work and is computed assuming that all the light of the corona is due to electron scattering It is evident that the computed polarizations of the electron component do not depend critically on the form of the distribution of electron density Curve *C* shows the actual polarization observed by von Kluber in the equatorial regions The reasonable agreement in the region close to the Sun (1 $0R_{\odot}$–1 $5R_{\odot}$) supports the electron scattering theory Farther from the Sun the observed polarization becomes progressively smaller than that required for a pure electron scattering model, the explanation for this in terms of *F* and *K* components is that the part scattered by electrons is being diluted by an unpolarized component due to scattering by dust This seems a quite satisfactory explanation which is quantitatively supported by other evidence (for example, the observed equivalent widths of Fraunhofer lines) which we do not consider here

The infra-red excess of the corona The colour and infra-red excess of the corona have also been the

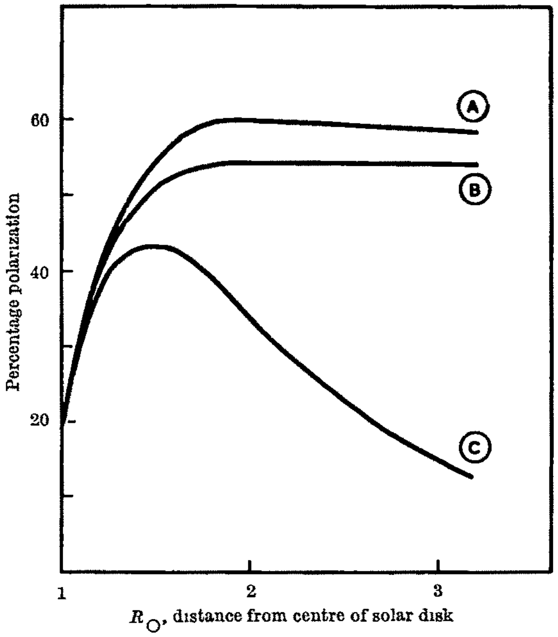

Fig 3 Observed and calculated polarizations of the solar corona, and their variation with distance from the solar limb Curve (*A*) polarization of *K* component only computed by von Kluber for his electron density distribution, (*B*) polarization computed by Baumbach, (*C*) actual polarization observed by von Kluber

subject of recent investigations Briefly, the results are that close to the Sun the colour is not significantly different from that of the average solar disk[9], but in the outer parts the infra-red excess becomes appreciable , at a distance of 2 5$R_\odot$ and at a wave-length of 1 9μ it has been measured to be 2 17 Such an excess is naturally explained by the diffraction theory of the *F* corona[10] That there is dust in the solar system is shown by the existence of the zodiacal light, and both van de Hulst[11] and Allen[12] have shown independently that both the *F* corona and the zodiacal light can be explained by a single model for the interplanetary dust The variation in infra-red excess mentioned by Kellogg and Ney is again accounted for by a varying ratio of electron component (with colour identical with that of the Sun) and dust component (which shows an infra-red excess)

We may remark here that after allowing for the dust corona in the conventional model the true electron densities in the outer solar atmosphere are considerably lower than indicated by the Baumbach curve in our Fig 1, and in fact are in rather better agreement with Kellogg and Ney's curve—but not for the reason these authors suggest However, at $10r_\odot$ there still remains a discrepancy of about ×40 between the true electron density and the lower value given by Kellogg and Ney

There is a contradiction here that is not satisfactorily explained by these authors in their article. If the conventional electron densities, or particularly Kellogg and Ney's densities, are accepted, the computed brightness at large distances from the Sun is much smaller than the observed brightness In conventional theory the extra light arises from dust scattering, but Kellogg and Ney attribute it to synchrotron radiation If this attribution is correct, synchrotron radiation must increase in importance with increasing distance from the Sun—and indeed we have shown that the infra-red excess increases in the outer corona But synchrotron radiation does not explain the existence of unbroadened Fraunhofer lines in these parts of the corona, although these lines are satisfactorily explained in terms of scattering by interplanetary dust particles far from the Sun

We shall not detail other criticisms which we feel could be made, but mention one last observational point Kellogg and Ney propose that if the solar corona is really analogous to the Van Allen particle belt, one might expect a maximum in the coronal intensity close to the Sun They believe that such a maximum might exist, supposing that "the problem of reversal in photographic emulsions has previously masked the possible presence of a maximum" So gross an effect as photographic reversal has not complicated the interpretation of eclipse photographs in any competent observations made since the 1890's There are in fact other much more subtle sources of error in the photometry of such a difficult object as the solar corona, and these errors may more readily be overlooked in photoelectric than in photographic photometry The most careful work in this region has never shown a maximum of the kind suggested by Kellogg and Ney, and its existence is very doubtful

We agree with Kellogg and Ney that further observations of the polarization over a greater range of wave-lengths are required and should be made at future eclipses Also, it is unfortunate that the most reliable measurements of polarization, and to some extent of infra-red excess, have been made near sunspot minimum , repetitions near maximum would be of value

However, we are of the opinion that the authors have not substantiated their claim that this interesting new theory accounts better for the observed properties of the corona While it may be that synchrotron radiation is a third contributor to the coronal light, we do not think the present observations support the postulate that sufficient synchrotron radiation exists to justify a major modification to the present two-component model of the corona

We wish to express our appreciation for the critical comments made by Drs Blackwell and Dewhirst concerning our suggestions about the nature of the solar corona We are not professional astronomers and for this reason we may have placed undue emphasis on certain published literature, with perhaps too little emphasis on other literature more generally accepted by astronomers We do feel, in spite of the remarks of Drs Blackwell and Dewhirst, that under each of the topics which were discussed in our original article, experimental evidence exists which makes the possibility of synchrotron radiation from a magnetically contained corona at least a very plausible hypothesis

The principal objection of Drs Blackwell and Dewhirst seems to rest on a question of terminology To us, the *F* corona is not a real part of the corona, but represents a spurious effect which must be removed In the interests of brevity, we omitted any mention of the experimental difficulty of separating the *F*-coronal light from that of the electron corona, except for one or two comments, but we are aware of at least part of the evidence for the existence of the *F* corona Thus the curve which we marked curve 1 in our Fig 1 is supposed to represent the electron density and not the total coronal light It was plotted as $1/R^6$ not by mistake, as Blackwell and Dewhirst imply, but to represent the currently accepted electron densities Eclipses subsequent to the one observed by Turner have led to electron densities falling off as $1/R^6$ instead of $1/R^5$, as would have been obtained from the 1898 eclipse alone In order to obtain electron densities at large distances, the *F* corona must of course be removed Considering the rough nature of the ideas involved and the difficulties of measurement, we consider that the result is in reasonable agreement with our curve We pointed out the similarity of the solar corona and the radiation belt to indicate the attractiveness of confining charged particles by a magnetic field, in contrast to a gravitationally confined atmosphere. The comparison with the Van Allen radiation is intended only to be suggestive, and obviously no very close agreement is to be expected However, the most recent observation of the radiation belt by the Iowa group shows even better agreement with the coronal curve 1 than the results shown in curve 3 of our original article

It is unfortunately true that the measurements of Zakharin were made with some instrumental difficulties and the resulting plates were not of the highest quality. Nevertheless, these and the other measurements quoted by us remain the only measurements of the direction of polarization of the coronal light which were made near sunspot maximum It seems very likely that synchrotron radiation will be observed only near solar maximum Again, Nikonov's measurements of the infra-red excess were probably not as well done as the measurements by Blackwell in the 1952 eclipse Nevertheless, as they stand, they do not agree with the idea that the infra-red excess is due to the scattering by dust, since Nikonov observed that the infra-red excess was greatest at sunspot maximum when the electron density in the corona is greatest, and therefore the relative contribution of the F corona should be least So long as there are no more modern experiments to replace this Russian work, the answer to the questions which we are discussing must remain in doubt

In defence of our basic idea, we believe that Drs Blackwell and Dewhirst have taken too seriously the details of our suggestion but have tended to overlook or misunderstand the main features of a trapped corona Our concept is that magnetic fields anchored at the surface can act as guiding centres for particles which may then be confined between mirror points, as they are in fact in the Earth's magnetic field We accept as a working hypothesis that magnetic fields exist in the region of the solar corona We also believe, because of cosmic-ray evidence, that the Sun is able to inject high-energy particles into these magnetic fields If high-energy electrons are injected into magnetic fields, then synchrotron radiation will automatically occur In fact, if the corona were examined in light of long enough wave-length, the synchrotron radiation would necessarily be observable We wish to emphasize the point, which was made in our article, that the extent of the trapping of particles in the corona may depend strongly on solar activity, and therefore polarization and infra-red excess measurements made at sunspot minimum are definitely not evidence against our suggestions

Perhaps the title of our paper, "A New Theory of the Solar Corona", was too ambitious, since our model requires so many of the constituents of the description of the corona currently accepted The comments made by Drs Blackwell and Dewhirst seem to indicate that they believe we would reject the description of the corona in terms of K and F corona This is not correct; we certainly believe that the majority of the visible light from the inner corona is produced by Thomson scattering by slowly moving electrons, and it is almost impossible to escape the conclusion that the outer corona must be largely composed of dust grains, as has been very effectively discussed previously by Dr Blackwell We feel, however, that ultimately some experiment will reveal the existence of trapped particles, and that it is possible that this experiment may consist of measuring in redder and redder light the polarization of the corona at times of high solar activity Should the experiments in the visible or near infra-red reveal synchrotron radiation, our postulate of the magnetically trapped corona would be confirmed However, we do not believe that the absence of synchrotron radiation at visible wave-lengths would disprove our hypothesis Our calculations show that in order to see synchrotron radiation in the visible region of the spectrum, an integral energy spectrum for trapped particles would be required that goes at least as slowly with energy as $1/E$ An energy spectrum which falls as steeply as $1/E^2$ would not produce synchrotron radiation in the visible region in great enough intensity to be seen against the background of the Thomson scattered light

The reason for presenting our article in *Nature* was that a study of the literature to which we referred had in fact convinced us that enough doubt existed as to the coronal polarization to justify an intensive experimental study of the problem at sunspot maximum In the months that have followed since its submission, we have designed and constructed electronic telescopes which use photomultiplier detectors and television raster scanning to measure the polarization out to three solar radii in a pattern consisting of approximately 900 individual points The polarization will be measured in fixed positions in the corona and the scan will proceed from one position to the next until the entire area is covered This method eliminates many of the inherent difficulties involved in photometric measurements of coronal polarization The equipment which we have designed is to carry out the programme just described six times during the total eclipse of October 2, 1959, and we therefore hope that, cloud-cover permitting, we will be able to contribute some useful results on this rather important problem

PROTON RESONANCE RELAXATION TIMES IN MOBILE LIQUIDS

By DR. J G POWLES and D CUTLER

Physics Department, Queen Mary College (University of London), Mile End Road, London

WE have measured the proton magnetic resonance relaxation times, T_1 at 250 ± 25 gauss and at 5,000 gauss and T_2 at 0 75 gauss, for a number of organic liquids and solutions at 25° C The results are summarized in Table 1

Although T_1 and T_2 have not been measured at the same field and so are not strictly comparable, the results suggest that T_2 may be appreciably shorter than T_1 The difference is most striking for the benzene solutions Some examples in which $T_1 = T_2$ have been observed, and also cases where more than one chemical type of proton is present have been studied[1,2]

Both T_1 and T_2 are strikingly shorter in fluorobenzene than in any of the other substituted benzenes The short T_2 is implicit in the results of Elliott and

Shumacher[3] at 0 55 gauss, although they do not claim to have measured a value of T_2

T_1 for the benzene solutions rises with dilution and would probably reach the value of $T_1 = 60$ sec observed by Nederbragt and Reilly[4] at 9,500 gauss for 8 per cent benzene in carbon disulphide measured by the recovery from saturation This emphasizes the anomalous nature of the T_2 values

The measurement of T_1 at any field-strength is straightforward Measurement of T_2 is much more difficult and values of T_2 in excess of about 1 sec require special care We have taken considerable pains to ensure a true measure of T_2, as has been briefly described[5], and which will be discussed in detail elsewhere[2]

For water a difference between T_1 and T_2 at 7,400 gauss has been reported[6] but the sample evidently contained dissolved oxygen and so the values are not strictly relevant The value of T_1 is well established and appears to be independent of the field A value of T_2 of 3 0 sec has been reported[7] and a value of 2 7 sec is implicit in the measurement of Meiboom and Gill[8] at 7,000 gauss Another result[9] appears to be T_2 in presence of a radio-frequency field

For benzene the value of T_1 of about 18 sec is well supported and is independent of the field A T_2 value of 16 ± 3 sec at 20° C and 0 5 gauss is reported from direct measurement of line-width[7] A reported value[10] of T_2 of 18 5 sec, at 2,000 gauss, was measured in the presence of the radio-frequency field, and theory[11,12] indicates that this T_2 should have the same numerical value as T_1, as observed We note an apparent dependence of the field of T_1 in bromobenzene and possibly in *cyclo*hexane

Although the difference of T_1 and T_2 is most striking for the longer relaxation times, it is more realistic to consider the quantity $(1/T_2) - (1/T_1)$ This is of order of magnitude 0 1 sec^{-1} If the relaxation times are shorter than about 1 sec, such a difference is difficult to observe[1]

Current theories of nuclear resonance relaxation[13,14,20] indicate $T_1 = T_2$ for these materials, since the molecular correlation time, τ_c, is of order 10^{-11} sec and the highest resonance frequency, ω_r, is of order 10^8 r/s so that $\omega_r\tau_c \ll 1$ A difference only arises for slow interactions, that is, $\omega_r\tau_c > 1$, and then it is usually very dependent on the field

The magnitude of the difference could be explained by the static interaction of any given proton with *one* other proton at about 300 A (about 50 molecular diameters), but since we have observed exponential decays, a substantial static interaction contribution is excluded This led us to consider the possibility that the difference could arise from interactions with distant protons which although weak, because of the factor r^{-6}, are numerous However, calculations in which the motional effects were allowed for, using the self-diffusion equation, showed that the effect is too small (We are grateful to Mr D P Rooke for assistance with these calculations) Most other known interactions make equal contributions to T_1 and T_2, for example, direct dipolar, anisotropic chemical shift, anisotropic indirect interaction and paramagnetic ions in low enough concentration The difference of T_1 and T_2 for water has been explained[6] in terms of the slow fluctuating field produced as a result of proton-exchange processes However, this effect should be proportional to the square of the field and it can scarcely explain benzene, *cyclo*hexane, etc The only moderately plausible general explanation we have found is that of a fluctuating isotropic indirect spin–spin (J type) interaction A constant J interaction does not cause line-splitting (except in fluorobenzene) because the protons are equivalent[15] However, if this coupling is explicitly dependent upon time, it becomes observable because the Gutowsky, McCall, Slichter[15] theorem is no longer valid It contributes to T_2 but not to T_1 A similar but not identical effect is found in liquid hydrogen fluoride[16] However, in order to produce $(1/T_2) - (1/T_1) \simeq 0$ 1 sec^{-1} with $J \simeq 10$ c/s, the coupling must be interrupted at about 10^5 times per sec This might be brought about by relatively infrequent 'violent' collisions between molecules Proton exchange is in this sense a violent collision The large effect in the benzene solutions would then be occasioned by the large electric fields produced by the polar solvent molecules However, interruption of J at this rate is unlikely, except in dissociating molecules, because J-type splitting of tens of cycles per second between inequivalent nuclei is observed in molecules in similar circumstances

Other experimental results on molecules containing more than one chemical type of proton will be discussed elsewhere[2]

The measurements of T_1 at 5,000 gauss were made by Mr A Hartland

Note added in proof A recent report[21] of measurements at 6,500 gauss shows precise agreement with our measurements for water but $T_1 \simeq T_2$ for benzene The explanation of the difference between T_1 and T_2 for water in terms of surface effects in the small sample seems scarcely applicable to our sample of 200 ml

POSSIBLE MECHANISM OF CYSTEINE PROTECTION AGAINST RADIATION CATARACT

By Mrs A PIRIE

Nuffield Laboratory of Ophthalmology, University of Oxford

AND

L G LAJTHA

Radiobiology Laboratory, Department of Radiotherapy, Oxford

EXPERIMENTS have shown that cysteine injected into an animal shortly before the eye is irradiated will largely prevent development of radiation cataract von Sallmann, Munoz and Barr[1] compared the histology of the lens epithelium in rabbits irradiated with or without a previous injection of cysteine and tentatively concluded that initial inhibition of mitosis by X-ray was unaffected, but that the number of nuclear fragments that developed after irradiation was smaller in the cysteine-treated lens von Sallmann *et al* used a dose of 1,500 r and it seemed possible that it might be easier to show histologically that cysteine affected radiation damage if the dose were nearer the threshold for mitotic inhibition We have therefore examined the effect of a pre-irradiation injection of cysteine on the mitotic inhibition, the subsequent mitotic overshoot and on the production of fragmented nuclei in the lens epithelium of rabbits using a dose of 500 r to the right eye The methods described by Pirie and Drance[2] were used Comparisons were made between litter mates and between right (irradiated) and left (not irradiated) lenses of the same rabbit These experiments have confirmed von Sallmann's earlier results The inhibition of mitosis is as great and even more prolonged after cysteine injection followed by X-irradiation than after X-irradiation alone The lens epithelium of the cysteine-treated rabbit shows no excess mitosis after inhibition has worn off In two experiments a dose of 300 r was given and again cysteine treatment did not prevent complete mitotic arrest at 24 hr Fig 1 shows that at all stages examined (2–28 days after X-ray) fewer fragmented nuclei were present in the lens epithelium of the cysteine-injected rabbit than in that of the animal irradiated without cysteine treatment

But we noticed that in the cysteine-injected rabbits the epithelium of the lens of the left, non-irradiated eye also showed an inhibition of mitosis This inhibition could be estimated through a comparison with the non-irradiated left eye of a litter mate not injected with cysteine In order to determine the degree and duration of this inhibition of cell division by cysteine a series of experiments was done in which one rabbit received an injection of cysteine and a litter mate was used as a control, no radiation being given to either Such pairs of rabbits were killed at intervals after the cysteine injection to one of the rabbits and comparisons made of epithelial

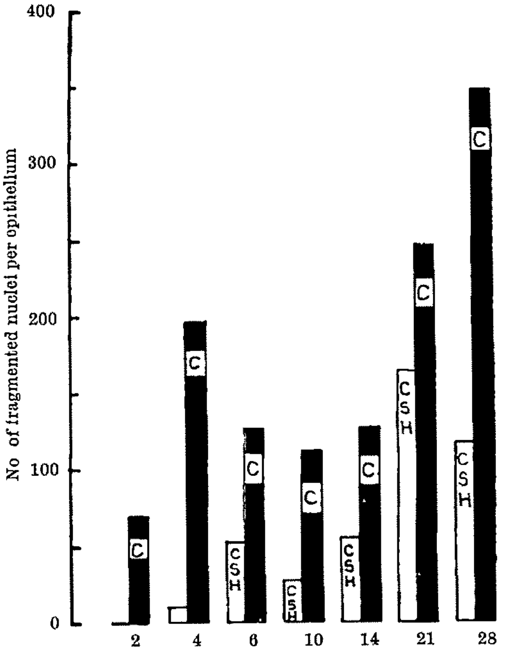

Fig 1 Effect of cysteine injection on the development of fragmented nuclei in the lens epithelium after X-irradiation

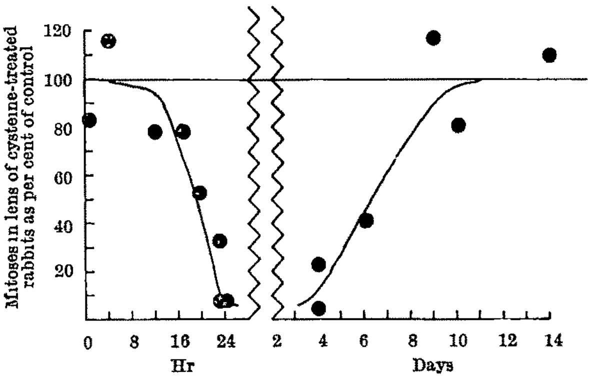

Fig 2 Effect of cysteine injection on mitosis in the lens epithelium

histology Fig 2 shows that cysteine injection arrests mitosis in the lens epithelium from 24 hr to 4 days This inhibition of cell division then gradually wears off without any subsequent excess of dividing cells or formation of fragmented nuclei or abnormal forms up to 28 days after cysteine injection

von Sallmann *et al* [1] had previously found in two rabbits that mitosis was normal 2 hr and 8 hr after injection of cysteine We examined lenses, 30 min , 4, 12 and 16 hr. after cysteine and found mitosis only slightly if at all depressed at these times The total number of dividing cells and the proportion in prophase and succeeding phases of mitosis were unchanged compared with the control lenses But at 20 hr mitosis was only 53 per cent of the control and at 23 hr it had fallen in one rabbit to 32 and in another to 8 per cent

1 gm /kgm is a very large dose of cysteine and was used only because this dose has been shown to prevent irradiation cataract For injection, cysteine hydrochloride was, in most experiments, neutralized with sodium hydroxide and injected, in a total volume of 5–8 ml , into the ear vein of the unanæsthetized rabbit It was noticed that the animals became almost immediately quiet, and in some cases their hind legs became inco-ordinated and they did not feed for some hours Controls injected with an equivalent amount of sodium chloride or 1 gm glycine per kgm did not show these signs, nor was there a fall in the mitoses of the lens epithelium In one experiment the cysteine hydrochloride was neutralized by shaking with 'Dowex-1'-bicarbonate resin, and the carbon dioxide blown off by passing nitrogen through the solution, thus avoiding the presence of sodium chloride in the solution to be injected The rabbits injected with this solution of cysteine showed the same signs of inco-ordination as those injected with cysteine neutralized with sodium hydroxide and the fall in mitosis in the lens epithelium was also apparent

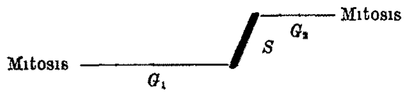
The question arises whether mitotic arrest by cysteine is related to its protective effect against X-ray damage to the lens von Sallmann, Dische, Ehrlich and Munoz[3] found that cysteine and cystine reached a maximum in the aqueous humour about 1 hr after intravenous injection After a dose of 2 gm cysteine to an adult rabbit a concentration of 40 mgm cysteine/100 ml aqueous humour (3 mM) was reached The concentration of cystine was about the same , both gradually declined over the next few hours Protection of the lens against radiation is effective 30 min after cysteine injection and, in spite of the fact that mitotic arrest cannot be demonstrated for at least 19 hr after cysteine injection, it seems reasonable to consider that the reaction(s) between cysteine or cystine and cell constituent(s) which leads to mitotic arrest must take place shortly after injection when cysteine and cystine are present in the aqueous humour von Sallmann *et al* [1] consider that mitosis in the lens epithelium may take only 30 min , but interphase must be prolonged, probably taking several days as in corneal epithelium (Friedenwald and Sigelman[4]) If cysteine interrupted some process early in interphase, all cells already past that point in the mitotic cycle could divide normally before any mitotic arrest became apparent This could explain the slow development of mitotic inhibition by cysteine

The effect of cysteine on synthesis of deoxyribonucleic acid was investigated in human bone marrow cells *in vitro* by measuring the incorporation of formate labelled with carbon-14 or thymidine labelled with tritium into deoxyribonucleic acid[5,6]

Cysteine, in a concentration of 1 mM, produced a 60–80 per cent depression of synthesis of deoxyribonucleic acid as indicated by grain counting on autoradiographs , a concentration of 0 1 mM also produced a significant depression, ranging from 30 to 50 per cent

The concentration used in the rabbits was 1 gm / kgm , which corresponds to a concentration of about 10 mM in the whole animal, the concentration in the aqueous humour being of the order of 1 mM (von Sallmann *et al* [3])

The following is a scheme of the intermitotic cycle where S is the period of synthesis of deoxyribonucleic acid, G_1 and G_2 are pre- and post-synthetic gaps respectively



If synthesis of deoxyribonucleic acid is reversibly depressed in a cell, the onset of mitosis will be delayed If the G_2 period is not affected then the delay in mitosis will appear only after a certain period, that is, cells already in G_2 period can proceed normally and enter mitosis, but the 'feed' of cells into the G_2 period will be depressed if the S period is elongated The findings on mitotic counts in lens epithelium indicate that this, in fact, may be the case the depression in mitosis by cysteine is observed only after a certain period (presumably corresponding to the length of G_2 period in these cells)

It is not known at this stage whether processes in the G_1 period are affected by cysteine or not It is unlikely, however, that such concentrations of cysteine would affect synthesis of deoxyribonucleic acid only—nuclear phosphorylation is known to be affected by large doses of cysteine (Stocken and Creasey, personal communication), and Mazia[7] has shown that mercaptoethanol will inhibit division of the fertilized egg of the sand dollar , he suggests this is due to a reaction between mercaptoethanol and the protein which forms the mitotic spindle He considers that formation of the fibrous spindle requires S—S links between protein molecules and that mercaptoethanol prevents their formation by competing with the available SS or SH groups

If the process in interphase which is interrupted by cysteine lies earlier than the process which is radiosensitive, then so long as arrest by cysteine is reversible, one can postulate that cysteine protection is related to its ability to arrest mitosis Such protection can never be complete, as some cells will be in a stage of the mitotic cycle that is insensitive to cysteine but is radiosensitive Cysteine protection against radiation cataract has in fact never been found to be complete

$$\text{division} \rightarrow \underbrace{a \rightarrow b \overset{\text{cysteine}}{-\!\|\!\!\rightarrow} c \rightarrow d \overset{\text{radiation}}{-\!\|\!\!\rightarrow} e \rightarrow f}_{\substack{\text{interphase} \\ \text{(several days)}}} \rightarrow \underbrace{\text{prophase} \rightarrow \text{division}}_{\substack{\text{mitosis} \\ \text{(30 min)}}}$$

The above scheme suggests a possible mechanism, but there is no evidence that this is a correct hypothesis, and the possibility of enhanced recovery phenomena in cysteine-treated cells should also be borne in mind At present there is only the observation that cysteine arrests cell division in the lens epithelium of the rabbit and that if given before irradiation the number of fragmented nuclei that develop afterwards is reduced Previous work has shown that cysteine largely protects from X-ray cataract

Thanks are due to the Medical Research Council and to the National Council to Combat Blindness Inc , New York, for expenses grants, and to Mrs M Overall for skilled technical assistance

RELEASE OF ADENOSINE TRIPHOSPHATE AND SEROTONIN FROM INJURED CELLULAR BLOOD ELEMENTS IN EXTRACORPOREAL CIRCUITS

By Dr. H S S SARAJAS, Dr. R. KRISTOFFERSSON and Dr. M. H. FRICK

Institute of Physiology, University of Helsinki ; Zoological Institute, University of Helsinki , and Wihuri Research Institute, Helsinki

CORPUSCULAR blood trauma, especially red cell and platelet damage, is still a problem inherent to extracorporeal circulatory systems, including the heart–lung machines[1,2] Hæmolysed blood has been reported to possess vasodilator properties attributed to the release of adenosine triphosphate and/or closely related compounds from injured red cells[3] Platelets, in turn, are known to contain large amounts of 5-hydroxytryptamine (serotonin)[4], a biogenic amine with powerful vasoactive, bronchomotor and other effects[5] In consequence, the question arose whether these humorally acting agents would be released into plasma in extracorporeal blood circuits and whether the resultant humoral pathological blood changes would serve as a guide for disentangling the mechanisms of some complications associated with the use of heart–lung machines for open cardiac surgery

As a tentative approach to the problem an arteriovenous (femoral artery–superficial jugular vein) shunt, consisting of a polythene tube 1 m long, was created in four dogs and five rabbits pretreated with subcutaneous pethidine hydrochloride (2 mgm /kgm) and anæsthetized with intravenous sodium pentobarbitone (30 mgm /kgm) To mimic the blood trauma in the current heart–lung machines with greater surface area, pumps and filters, the inner surface of the shunts was intentionally 'cleaned' with steel-wool Just prior to opening of the shunt the animals were heparinized (5 mgm /kgm) In the period of extracorporeal circulation via the shunt the corpuscular blood changes and the whole blood- and plasma-levels of adenosine triphosphate and 5-hydroxytryptamine were observed For that purpose three blood samples of about 4 ml were taken with a siliconized syringe needle from a rubber tube incorporated to the shunts The first blood sample was taken immediately after opening of the shunt and the subsequent samples 30 and 90 min later The corpuscular blood changes were determined by using routine techniques The whole blood- and plasma-levels of adenosine triphosphate were determined by the colorimetric micromethod of Rehell *et al* [6] The 5-hydroxytryptamine content of whole blood and plasma was, after overnight extraction in cold acetone (4° C), assayed by the method of Erspamer[7] based on the contraction of œstrous virgin rat uterus The urinary excretion of this substance and 5-hydroxyindoleacetic acid (the main excretory product of 5-hydroxytryptamine) was studied in dogs only The urinary bladder was catheterized immediately after induction of anæsthesia Then the urine excreted before (45 or 90 min) and during (90 min) extracorporeal circulation was collected, measured for volume and analysed for 5-hydroxytryptamine and 5-hydroxyindoleacetic acid The former was assayed by the same technique as that in blood and plasma, the latter according to the spectrophotometric method described by Udenfriend and associates[8]

No major alterations were found in the whole-blood adenosine triphosphate during extracorporeal circulation This was particularly true for dogs, while in rabbits some decrease in the whole-blood adenosine triphosphate became evident The erythrocyte count and the hæmatocrit values, correspondingly, remained substantially unaltered in dogs, while in rabbits there was some decrease in the erythrocyte count and hæmatocrit values At the start of extracorporeal circulation no adenosine triphosphate was detected in the plasma of either rabbits or dogs In both rabbits and dogs, however, increasing amounts of adenosine triphosphate appeared in the plasma during extracorporeal circulation, the rising trend being more pronounced in rabbits than in dogs (as terminal phosphate-P., from zero to an average of 0.9 mgm./100 ml. and from zero to an average of 0.35 mgm./100 ml., respectively). We had the impression that the degree of hæmolysis, estimated visually from the colour of the plasma in the successive samples, paralleled the changes in the adenosine triphosphate of the plasma; with increasing hæmolysis more adenosine triphosphate was detected in the plasma. The whole-blood 5-hydroxytryptamine generally showed a clear-cut trend to decrease during extracorporeal circulation in both rabbits and dogs. Concomitantly the platelet counts fell, while the plasma 5-hydroxytryptamine levels were increased. Again, the drop in the platelet count was more pronounced in rabbits than in dogs (on the average from 318,000 to 71,000/cu.mm. and from 329,000 to 249,000/cu.mm., respectively). The same held for the fall in the total white cell count observed in both rabbits and dogs. In contrast to the plasma adenosine triphosphate, considerable activity of 5-hydroxytryptamine was found in the plasma at the start of extracorporeal circulation (average 0.2 μgm./ml. in rabbits and 0.025 μgm./ml. in dogs). In rabbits the levels of plasma then steadily increased during extracorporeal circulation (up to an average of 0.38 μgm./ml.). In dogs the plasma 5-hydroxytryptamine increased in the early period of extracorporeal circulation (on the average from 0.025 μgm./ml. to 0.045 μgm./ml.), but towards the end of extracorporeal circulation 5-hydroxytryptamine of the plasma showed some tendency to fall. The urinary excretion of 5-hydroxytryptamine in dogs prior to extracorporeal circulation averaged 0.002 μgm./min. In two of the four dogs there was actually no activity of 5-hydroxytryptamine in the urine before extracorporeal circulation. In the urine collected during the period of this circulation the activity of 5-hydroxytryptamine was consistently increased; the urinary excretion of 5-hydroxytryptamine attained an average level of 0.005 μgm./min. Reverse changes were noted in the urinary excretion of 5-hydroxyindoleacetic acid; this fell from an average of 0.78 μgm./min. before extracorporeal circulation to an average of 0.38 μgm./min. during this circulation.

Adenosine compounds are presumably liberated from all injured tissues. Platelets, for example, are rich not only in 5-hydroxytryptamine but also contain appreciable amounts of adenosine triphosphate[9]. However, proceeding from the knowledge that red cells are particularly rich in adenosine compounds, including the phosphate[3,6], that they are susceptible to mechanical trauma[3] and that their total mass in the circulatory system is enormously greater than that of the other cellular blood constituents, it is obvious that the red cells were the main source of the adenosine triphosphate released into the plasma in the present experiments. According to Udenfriend and Weissbach[4], platelets contain all the 5-hydroxytryptamine present in the whole-blood, while none is found in the plasma. Yet we found considerable activity of 5-hydroxytryptamine in the plasma already at the start of extracorporeal circulation. This may be explained by the fact that after short centrifugation at low running rates, as used to avoid hæmolysis in the present experiments (for 10 min. at 2,000 r.p.m.), the plasma still contains platelets[10]. Nevertheless, the gradually increasing levels of plasma 5-hydroxytryptamine during extracorporeal circulation, with an associated fall in the platelet counts, indicate that 5-hydroxytryptamine was steadily liberated from disintegrated platelets. The consistently increased urinary excretion of 5-hydroxytryptamine during extracorporeal circulation further indicates that 5-hydroxytryptamine was actually released into the plasma in the period of this circulation, for increased urinary excretion of 5-hydroxytryptamine has been observed after administration of exogenous 5-hydroxytryptamine[11]. Finally, the definitely higher levels of whole-blood (and plasma) 5-hydroxytryptamine in our rabbits as compared with those in dogs, the platelet counts being equal, are in agreement with the figures for 5-hydroxytryptamine content of platelets in these species[4].

The blood trauma in the present experiments was of the same general degree as that in the current heart–lung machines. On the other hand, exogenous adenosine triphosphate and 5-hydroxytryptamine at minute dose-levels have been reported to elicit vasodilatation and systemic hypotension[3,5,12]. Intense bronchoconstriction[5], pulmonary vasoconstriction[5] and potentiation of the action of hypnotics (barbiturates)[13] are further reactions to exogenous 5-hydroxytryptamine. With these facts in mind it seems possible that the complications associated with the use of heart–lung machines for open cardiac surgery, such as hypotension, cyanosis and a delay in the recovery from anæsthesia with eventual death[2], might be largely effected by such physiologically highly active agents as adenosine triphosphate and 5-hydroxytryptamine liberated into plasma from injured cellular blood constituents. Significantly enough, even in the present experiments deepening of the anæsthetic-level during extracorporeal circulation, as well as a delay in the recovery from anæsthesia, were repeatedly observed. In addition, 5-hydroxytryptamine has been found to be about one hundred times as effective as histamine in raising capillary permeability and in producing œdema[14]. Taken together with the above results, it also seems possible that such unexplained features as the œdematous changes in perfusion preparations of different types and more particularly the myocardial œdema, continuously increasing coronary flow and "Spontaninsuffizienz" known to occur in the heart–lung preparations[15] would be causally related to the humoral pathological blood changes under consideration. The present results are being described and discussed in detail elsewhere[16].

AMPLITUDE-MODULATION RADIO-TELEMETRY OF NERVE ACTION POTENTIALS

By ROGER M. MORRELL*

Montreal Neurological Institute, Montreal 2

INFORMATION concerning the functioning of intact animals has been successfully telemetred to remote points from satellites, missiles, large centrifuges and other situations[1]. The present report describes experiments in which the response of a single type of excitable tissue (nerve trunk or fibre) was relayed to and recorded at a distant point by telemetry. The basic problem is one of transmitting a pulse to the preparation at a distant point, and receiving the response to this stimulus at the point of transmission.

This series of experiments passed through several phases which will be described in another communication[2]. The system made use of two radio links, one for each direction in which information was to flow, and was set up in one building. The required stimulating pulse was produced by a Grass *S4-C* stimulator and used to amplitude-modulate a Hallicrafters *S-27RS* radio transmitter by means of the Model 115 amplitude-modulator of Measurements Laboratory (Boonton, New Jersey). The modulator operated at a minimum external modulating frequency of 30 cycles, provided up to 100 per cent modulation with low envelope distortion, allowed accurate metered per cent modulation calibration, and produced amplitude modulation of the stimulus intelligence with negligible accompanying incidental frequency modulation, thus allowing narrow-band receiver operation. In accordance with amplitude modulation theory, the stimulus, or modulating voltage, was introduced in the plate voltage supply line and added to the plate supply voltage at a rate and magnitude determined by the modulating signal and the modulator output. In this type of system, developed by Hartley, the carrier signal originates in a crystal-controlled oscillator, is raised to full power by amplifiers, and is modulated in the final stage of power amplification which operates Class *C*. Since the load is fixed, as the voltage level changes because of the modulation, the tank voltage swing, the plate current operating angle, and the current-pulse form and amplitude change so that the d.c. plate voltage varies linearly with respect to the square root of the power output. This permits distortionless amplitude modulation, but the modulator must supply power equal to one-half of the unmodulated carrier power at 100 per cent modulation.

The radio-frequency carrier can be expressed as $y = A(t) \cos \gamma(t)$ and in amplitude modulation the signal intelligence (nerve stimulus and response) is made to control the amplitude parameter of the carrier by the relation

$$\begin{aligned} A(t) &= [A0 + af(t)] \\ &= [A0\{1 + maf(t)\}] \end{aligned}$$

The scheme for the plate-operated output stage and a block diagram of the entire system will be found in Fig. 1. A complete mathematical analysis of the carrier and amplitude spectra may be found elsewhere[3].

The antenna used to recover the signal at a distant point was a vertically mounted dipole designed for optimum reception of the tuned frequency (72.25 Mc./s.), fed into a coaxial transmission cable. The intelligence present in the amplitude-modulated wave was recovered by impressing the modulated

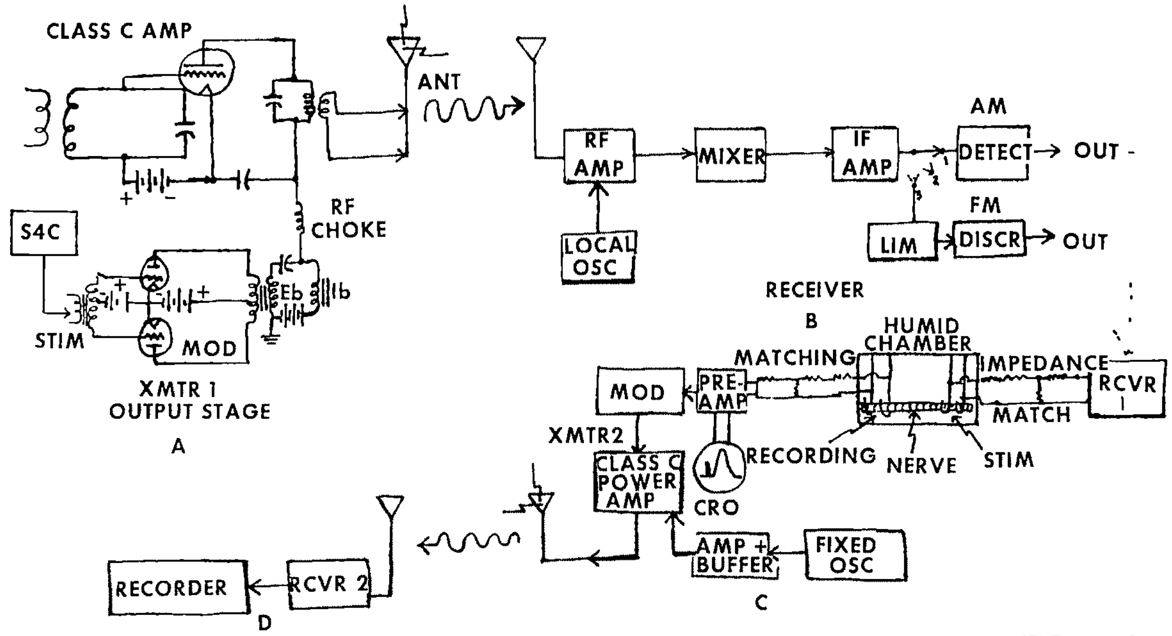

Fig. 1 (A). Plate-modulated output stage. Explanation in text. Transmitter I relays stimulus signal to receiver I. (*B*) Receiver I demodulates signal intelligence and (*C*) impresses stimulus on to stimulating electrodes via impedance network. Pick-up electrodes feed response through matching network to transmitter II, then relay response (also monitored on CRO) back to (*D*) receiver II, where it is demodulated, amplified and drives pen-recorder

wave on a non-linear network which, for low-strength signals, employed a voltage-current characteristic represented by the following terms of a Taylor series

---

* Formerly Senior Assistant Surgeon, USPHS Hospital, Staten Island, N.Y.

$$i = I_b + G_1 e + G_2 e^2 \qquad (1)$$

where the predominant term is G_2e^2 The carrier and first side-frequency pair which result from the amplitude-modulation of the carrier $E_0\sin\omega_0 t$ by the modulating wave $ME_0\cos\omega_1 t$ were impressed at the input of this network The impressed voltage, containing the stimulus intelligence, can then be written

$$e = E_0\sin\omega_0 t + \frac{ME}{2^0}\{\sin(\omega_0 + \omega_1)t + \sin(\omega_0 - \omega_1)t\} \qquad (2)$$

It is found by combination and substitution that the square-law term yields a series of waves The wave corresponding to the original intelligence is $G_2ME^{2\cos\omega_1 t}$ Its amplitude is proportional to the square of the voltage This wave was then amplified and fed through a network which matched the output impedance of the receiver to the bipolar stimulating electrodes. In operation, the receiver's *S*-meter was used as a carrier-level indicator for amplitude modulation, and the best records were obtained with the receiver tuned slightly to one side of the carrier frequency A Ferris model 18-*B* signal generator was used to align the receiver, which was also a Hallicrafters model *S*-27*RS* In later experiments employing frequency modulation a separate stage of the receiver assembly, known as the 'frequency unit', rectified the alternating current output of the receiver, and the d c output of the frequency unit was fed to a visual meter and recorder

The response of the preparation was picked up by silver–silver chloride electrodes, and after source-impedance matching and amplification, modulated another radio transmitter which transmitted the information back to the originating point Here, after demodulation and amplification, the pulses were used to activate a strip-chart recorder (Leeds and Northrup Speedomax Type *G* Model *S* 60000 series) Sciatic nerves of bullfrogs (*Rana catesbiana*) and radial or ulnar nerves of dogs (*Canis canis*) were used A total of 11 nerves was tested Single motor fibres were used in some experiments, which closely followed the bridge-insulator technique of Tasaki[4] Details of those studies will be included in ref 2 With the distal end crushed, whole nerves were placed on two pairs of electrodes in a humid chamber at 20° C The location of the active pick-up electrode was 7 5 cm distal to the stimulating cathode and 1 2 cm proximal to the inactive pick-up electrode The distal electrode was connected to earth and the proximal one was anode during the pulse The monophasic action potential was monitored at the site of the preparation by d c amplification and display on an oscilloscope The stimulating pulse, measured at the output of the distant receiver, was 0 1–0 5 msec in duration, and its amplitude was adjusted to be supramaximal for beta fibres

The duration of the responses was 1–3 msec and the maximum amplitude about 30 mV The wave form of the action-potential was not recorded, but simply the fact of its having occurred The portion of the record in Fig 2 shows the responses of the inkwriter to slow stimulation rates, and shows also that the write-out is proportional to amplitude Thresholds as determined by the onset of activity of the inkwriter varied from 14 to 15 mV , and did not differ significantly for amphibian as compared with mammalian nerve

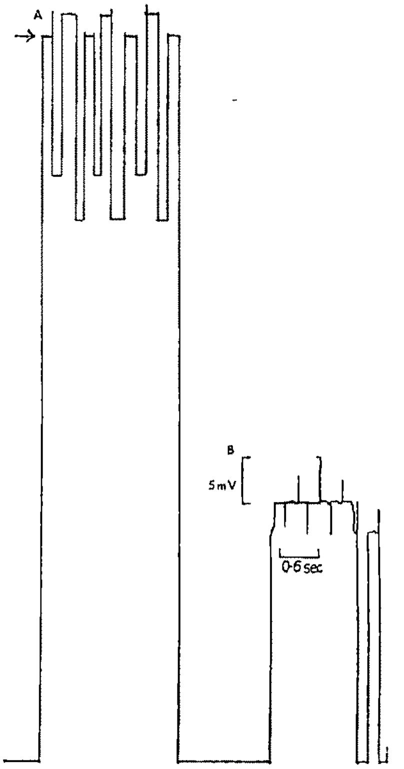

Fig 2 Photograph of segment of ink write-out showing (*A*) threshold of 15 mV (at arrow) for a single nerve

Conduction velocity was determined by the spacing between the rectangular pulse outlines on the record and ranged in all nerves from 23 5 to 36 8 m /sec In some experiments reproducible records were easily obtained for 15–20 hr , during part of which the whole system could be left unattended except for changing the paper or filling the ink-reservoir of the recorder For auditory monitoring during such periods a loudspeaker was connected to the 5,000-ohm terminals of receiver II

The special problem encountered in this application of telemetry is the matching of receiver output and input impedance-levels to bipolar stimulating and recording electrodes and the matching of the transmitter modulator inputs to the output of the stimulated nerve, with the assumption that the resting resistance is about 20 k -ohms max and that the resistance during activity is no more than 10 per cent of that value

Theoretically it is possible for the nerve to be stimulated by the carrier wave itself In general, for carrier frequencies at which losses in the preparation are not too great, the shape of the carrier envelope for the directly applied carrier would be expected to have the same shape as that obtained with a d c pulse Since the response is transmitted over a radio link it is more convenient to use the d c pulse for stimulation

The electrical process of the nerve impulse is a signal similar to those encountered in data-handling telemetry systems used for aircraft and missile testing and for satellite experiments It is now possible to determine the effect on the whole nerve or single fibre (if properly packaged) of magnetic, gravitational or radiation fields at very high altitudes, in vehicles undergoing changes in acceleration The long periods of time during which the output of the nerve is relatively constant when stimulated remotely by a constant stimulus assure adequate data for statistical analysis The method therefore allows measurement of changes in angular acceleration, both positive and negative Basic physiological data which can be collected in such circumstances include threshold, rheobase, chronaxie, strength-duration and strength-latency curves, refractory periods and critical stimulus interval for 2 stimuli Controlled variation in potentials led from electrodes implanted in animal brains can also be studied by this means, either on the ground or in guided or orbital flight By using a frequency modulated/frequency modulated multichannel system of the type commonly employed in satellite research, the wave-form of the action potentials can be recovered with fidelity through high-frequency interrogation during the passage of impulses Its relationship to environmental variables can then be determined With interval-measuring equipment at present available, nerves might be used in orbital vehicles as biological clocks to determine directly whether or not there is a relativistic shift for excitable tissue[5] This cannot be done at present with intact animals or astronauts

I wish to thank Messrs W Boynton, R Bottom, and A Fisher of the United States Weather Bureau for valuable advice concerning the operation of the transceiver units Mr P Baby of Electromechanical Research, Inc , furnished helpful references

COMPOSITION OF A PARAFFIN WAX FRACTION FROM TOBACCO LEAF AND TOBACCO SMOKE

By Dr W. CARRUTHERS and Dr. R A. W JOHNSTONE

Medical Research Council Carcinogenic Substances Research Group, University of Exeter

THE paraffin wax of tobacco leaf and smoke is generally regarded as a mixture of *n*-paraffinic hydrocarbons, with *n*-hentriacontane as the major component[1-3] The isolation of pure paraffinic hydrocarbons from both leaf and smoke has been claimed in a number of instances[4,5], but it is open to question whether the specimens were, in fact, homogeneous, for in every case the melting point was the only criterion of purity employed and it has been shown that melting points alone do not afford a reliable guide to the purity of paraffinic hydrocarbons[6]

We have obtained additional evidence of the complex nature of the wax through mass spectroscopic and gas-liquid chromatographic analyses of fractions obtained from green tobacco leaf (*Nicotiana tabacum*, Delcrest variety), from the 'black' fermented tobacco of a variety of Argentinian cigarettes and from the smoke of these cigarettes The analyses were very kindly carried out for us at Thornton Research Centre, 'Shell' Research, Ltd , through the generosity of Dr R Graham, and the results, shown in Tables 1 and 2, indicate clearly that the wax from each of the three sources is a mixture of broadly similar composition *n*-Hentriacontane is the main individual component, but appreciable quantities of the neighbouring odd-numbered homologues and small amounts of the even-numbered homologues are present as well Dr Graham has informed us that the precision of the mass-spectroscopic analysis is not high, and no significance should thus be attached to the apparent small differences in composition of the three waxes An interesting and novel feature of the results is the high proportion of *iso*-alkanes disclosed by mass spectroscopy So far as we are aware, *iso*-alkanes have not previously been detected in the paraffin wax of tobacco or indeed of other plants, although their presence in cigarette smoke has been noted[3] (Since writing this article, we have seen a publication by Mme Suzanne Barbezat (*J Recherches du Centre National de la Recherche Scientifique*, 45, 273 , 1958) in which it is reported that the paraffins of tobacco and tobacco smoke, though predominantly normal, may contain branched chain isomers Dr A I Kosak has also informed us that he and Dr J S Swinehart have detected branched chain isomers in the paraffin fraction of cigarette smoke We are

* These peaks were composed of two unresolved peaks The results given include both peaks The impurity is probably a very slightly branched paraffin

† These peaks were probably due to $n-C_{30}$ paraffins but this was not fully confirmed

indebted to these authors for telling us of this result before publication) The Thornton workers have interpreted the present results as due to the presence of 2-methylalkanes

For the preparation of the materials for analysis, neutral extracts of the tobacco and a neutral fraction of the cigarette smoke condensate were chromatographed on alumina and the initial waxy fractions eluted with light petroleum (b p 40–60° C) were treated with urea in warm methanol[7] The resulting adducts were washed with light petroleum, decomposed with water, and the recovered paraffins crystallized once from benzene-ethanol The melting points and elementary analyses are shown in Table 3 The waxes showed no light absorption in the ultra-violet, indicating the absence of unsaturated compounds, and their infra-red spectra determined on a Perkin–Elmer 'Infracord' spectrometer were very similar to that recorded for *n*-triacontane[9] The method of isolation does not rule out the presence of *iso*-paraffins, for it is known that slightly branched paraffins will form urea adducts if the main chain is long enough[8] Attempts to obtain additional evidence for the presence of *iso*-alkanes by high resolution infra-red spectroscopy in the 1,500–1,300 cm^{-1} region were inconclusive in the absence of suitable reference compounds

Source of wax	Green leaf	Fermented tobacco	Cigarette smoke
Melting point	60–63° C	60–63° C	61–64° C
Elementary analyses	C, 85 4 H, 14 5	C, 85 4 H, 14 3	C, 85 4 H, 14 5

Little consideration appears to have been given to the possibility that the considerable amounts of paraffin wax in cigarette smoke may play some part in its carcinogenic activity[10] In this connexion, attention might be directed to the report by Horton, Denman and Trosset[11] that the production of tumours on mouse skin by 3 4-benzpyrene and by 20-methylcholanthrene was considerably accelerated and the tumour incidence increased when the carcinogens were applied in conjunction with a large excess of certain high molecular weight hydrocarbons, including some *n*-paraffinic hydrocarbons It is not inconceivable that a similar combined action of the paraffins and the carcinogenic aromatic hydrocarbons[12] in cigarette smoke may contribute to the carcinogenic activity towards mouse skin of the smoke, and may account, in some measure, for the fact that the smoke is more potent than might be expected from its very small content of aromatic hydrocarbon carcinogens[13]

In other experiments we have prepared the methyl esters of acids obtained from the flue-cured tobacco of a variety of British cigarettes, and a fraction of the esters b p 190–210°/0 5 mm has also been analysed by mass spectroscopy and gas-liquid chromatography at the Thornton Research Centre To obtain the esters the tobacco was extracted with chloroform, and the alkali-soluble fraction treated briefly with ethereal diazomethane The mass spectroscopic results (Table 4) show that methyl palmitate is the major component of the mixture, accompanied by some stearate and smaller amounts of a number of other higher and lower homologues A considerable amount of C_{18} unsaturated esters is also present, with methyl linolenate predominating An essentially similar result was obtained in the gas-liquid chromatographic analysis Most of the acids corresponding to these esters have already been found in cigarette smoke, in which palmitic acid and C_{18} unsaturated acids appear to be particularly abundant[2,5] Palmitic acid was also found to be the principal fatty acid of an American bright green leaf by Hellier[14], and it is of interest that the palmitate and linolenate were the main components of a mixture of solanesyl esters recently isolated from an American flue-cured leaf[15] A mixture said to contain methyl laurate, myristate and palmitate has also been obtained from a Japanese flue-cured tobacco[16]

Table 4 MASS SPECTROSCOPIC ANALYSIS OF TOBACCO METHYL ESTERS*

Ester	Acid carbon No	Ester molecular weight	Peak height	Relative sensitivity	Relative quantity
Caprate	10	186	6	0 20	30

HÆMOGLOBIN *P* IN A FAMILY IN THE BELGIAN CONGO

By Dr. PAULETTE DHERTE
Laboratoire Médical, Stanleyville

Dr. H. LEHMANN
St Bartholomew's Hospital, London

AND

Dr. J. VANDEPITTE
Université Lovanium, Léopoldville

A SURVEY of abnormal hæmoglobins has been carried out on 1,000 African pregnant women visiting the Outpatients Department of the Government Hospital at Stanleyville. The results will be published in detail elsewhere, but it is of interest here that on two occasions hæmoglobin *P* was discovered. Hæmoglobin *P* was first described by Schneider and Haggard[1]. On paper and open boundary electrophoresis at alkaline *p*H, hæmoglobin *P* moves more slowly to the positive pole than hæmoglobin *A* and separates from that pigment. It moves faster than hæmoglobin *S* but does not separate from a mixture of *S* and *P*. Under these conditions it cannot be distinguished from hæmoglobin *L*. On electrophoresis in acid *p*H, either in citrate agar or by the open boundary technique, and in resin chromatography, hæmoglobin *L* separates widely from hæmoglobin *A*, whereas hæmoglobin *P* does not separate. Thus hæmoglobins *L* and *P* can be differentiated by these procedures.

In one of the findings of hæmoglobin *P* an extensive family study was made (Fig. 1). The propositus was a 24-year old Bantu female of pure Lokele descent. Originally the Lokele lived on the River Congo, but the propositus and her family had settled in Stanleyville. She was eight months pregnant when first seen and seemed perfectly well. She had three children who were alive and healthy. Laboratory examinations revealed the presence of *Pl. falciparum* in her blood and ankylostoma ova in her stools. She suffered from a moderate hypochromic anæmia, which was corrected by treatment with antimalarials and iron, and the mean corpuscular hæmoglobin concentration rose from 26 to 31·8 per cent, and the mean corpuscular hæmoglobin from 24·3γγ to 31γγ. Her serum iron-level at the end of the treatment was 117γ per 100 ml.

On paper electrophoresis at alkaline *p*H her hæmoglobin separated into two fractions, one hæmoglobin *A* and another moving more slowly in

the positions of hæmoglobins *L* or *P*. On resin chromatography at *p*H 6 the hæmoglobin mixture did not separate, although a tail appeared at the rear of the hæmoglobin *A* band, which is the typical appearance of a hæmoglobin $A + P$ mixture. We sent two samples of the patient's hæmoglobin to Dr. R. Schneider, who confirmed by paper electrophoresis at *p*H 8·6 and by open boundary electrophoresis at *p*H 6·4, and by electrophoresis in citrate agar at *p*H 6·0, that the abnormal hæmoglobin had the properties of hæmoglobin *P*.

When the family was examined it became apparent that a number of them showed traces of hæmoglobin *F*, but the hæmoglobin fraction A_2 was always below 3 per cent (Table 1). This applied to the parents of the propositus, to all her children, to one of her siblings, and seven of eight nephews and nieces examined. Two of her siblings showed no hæmoglobin *F*, but two nieces with hæmoglobin *F* were the daughters of one of these siblings. The family tree did not show an association of hæmoglobin *F* with either hæmoglobins *A* or *P*, or with a third hæmoglobin occurring in the family—hæmoglobin *S*. The only case where the amount of hæmoglobin *F* was considerable was that of a niece (III 9)—a two-year old child with 19 per cent fœtal hæmoglobin. There was a slight hypochromia but no serious anæmia, and there was no increase in hæmoglobin A_2 as might be expected in typical thalassæmia.

In one of the propositus' brothers (II 1) four hæmoglobins were found. Alkaline denaturation and resin chromatography at *p*H 6 demonstrated 4 per cent hæmoglobin *F*. On paper electrophoresis at *p*H 8·6 two fractions were seen: hæmoglobin *A*, and another larger, slow-moving component in the position of hæmoglobin *S*. On chromatography at *p*H 6 three fractions were seen, one corresponding to hæmoglobin *F*, and two others: one in the position of hæmoglobin *A* with tailing resembling the appearance of an $A + P$ mixture, and another in the position of hæmoglobin *S*. Whereas the fraction in the position of hæmoglobin *S* had been the largest on paper electrophoresis at alkaline *p*H, it was now smaller than the component moving in the position of hæmoglobin *A*. These findings could be interpreted as indicating the presence of hæmoglobins *A*, *P* and *S*, the *P* moving with *S* on alkaline paper electrophoresis, and with *A* on chromatography *p*H 6. The family study supported this interpretation. This man had married a woman with normal hæmoglobin, and three of his offspring showed hæmoglobins $A + P$, and three others hæmoglobins $A + S$. The genotype $A + S + P$ was therefore borne out by the family study.

Hæmoglobins *S* and *C* have been shown to be determined by allelic genes[2]. Ingram[3], and Hunt and Ingram[4] have demonstrated that the difference between hæmoglobins *A*, *S* and *C* consists in a substitution of different amino-acids in one position of the hæmoglobin half-molecule. The possibility that there might be more than one locus determining specific features of adult hæmoglobin was first suggested by Schwartz and his colleagues[5] to explain the mode of inheritance of hæmoglobins *A*, *S* and what they considered to be hæmoglobin *G*, in a family they had studied. This interpretation has also been proposed by Smith and Torbert[6] to explain their

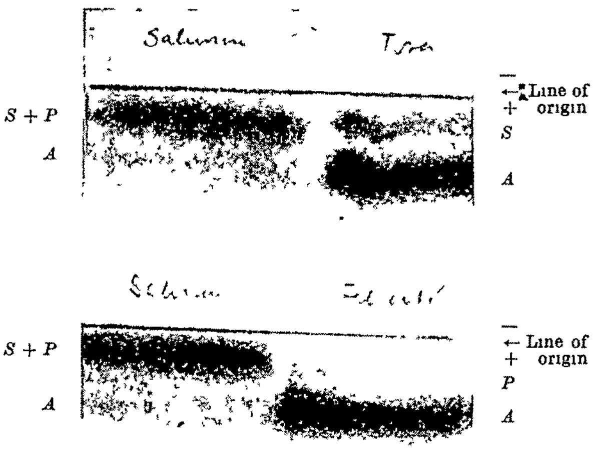

Fig. 2. Paper electrophoresis at *p*H 8·9 (*tris* buffer) showing above II 1 ($A + P + S$) in comparison with his son III 4 (showing $A + S$) and below with his daughter III 5 showing $A + P$. The bands are unstained

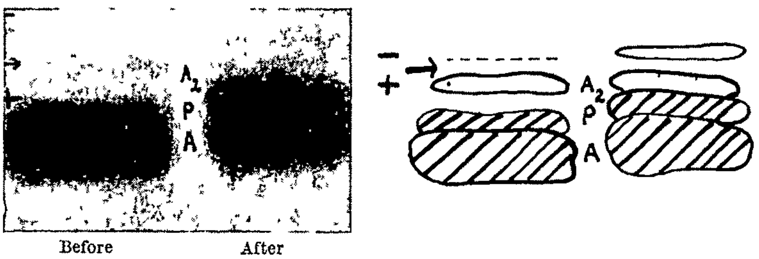

Fig. 3. Hæmoglobin from the propositus ($A + P + F$) before and after dissociation and re-combination. Paper electrophoresis at *p*H 8·9 (*tris* buffer). The bands are stained with 'light green'. In the re-combined specimen a small component is seen moving towards the anode

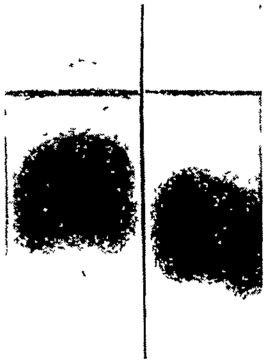

Fig 4 Paper electrophoresis at *p*H 8 6 (barbiturate buffer) showing a comparison between the hæmoglobin of the propositus ($A + P + F$) and a hæmoglobin $A + S$ mixture after dissociation and re-combination The bands have been stained with 'light green' Note that in the specimen from the propositus a fraction is present which moves towards the anode This fraction is not present in the $A - S$ mixture

findings in a family with hæmoglobins A, S and a 'fast' moving hæmoglobin Lastly, Cabannes and Portier[7] have described a family where the mother possessed hæmoglobins A, D and K One of her children was a hæmoglobin D trait carrier, and the other two were hæmoglobin K trait carriers It seems that hæmoglobin P joins the group of adult variants whose inheritance could be interpreted as being under different control from that responsible for hæmoglobins S and C Rhinesmith, Schroeder and Pauling[8] demonstrated that the hæmoglobin A molecule contains only two types of polypeptide chains, and Schroeder and Matsuda[9] have shown that hæmoglobin F also consists of an equal number of two polypeptide chains, one of which has been found by Hunt[10] to be identical with that common to hæmoglobins A, S and C Ingram[11] has pointed out how two non-allelic genes could find expression by one affecting the first, and the other the second, chain Singer and Itano[12] were able to show that exchange of chains between hæmoglobins A, S and C did not result in any 'hybrid' hæmoglobin This one would expect if in all three hæmoglobins one of the two chains was identical On the other hand, if in hæmoglobin P the alteration was not in the same chain which is different in hæmoglobins S, C and F, then a dissociation and re-combination of a hæmoglobin mixture containing hæmoglobins A, P and F should result in at least one 'hybrid' hæmoglobin

Following Singer and Itano[12] a purified solution of hæmoglobin from the propositus ($A + P + F$) was incubated with acetate buffer *p*H 4 6 It was then dialysed against barbiturate buffer *p*H 8 6, and a small amount of precipitate formed during dialysis was removed by centrifugation On paper electrophoresis of the supernatant at *p*H 8 6 a new hæmoglobin fraction was seen moving towards the cathode (Fig 3) This fraction could be eluted and was shown spectroscopically to be a hæmoglobin No such fraction was found when specimens of hæmoglobins $A + S$, $A + C$, and $S + C$ were similarly examined However, when untreated specimens of hæmoglobin from the propositus were submitted to starch electrophoresis where a larger amount of pigment could be investigated, a minute fraction corresponding to the 'hybrid' hæmoglobin was detected (Fig 3) It is not possible to state with assurance that this fraction was not formed on storage of the hæmoglobin solution However, if the 'hybrid' hæmoglobin was an *in vivo* phenomenon, the situation would resemble that known to occur in plants where anthocyanin formation is determined by independent genes, and 'hybrid' pigments can be formed In II 1 ($A + S + P + F$) only the 'hybrid' seen in the propositus was found on dissociation and re-combination of the hæmoglobin mixture Similarly, mixtures of hæmoglobins $A + S$, or $S + C$ with that of the propositus did not result in additional 'hybrids' However, here a large amount of precipitate was formed during dialysis and the soluble fraction had lost most of the non-A hæmoglobins

From the position of these hæmoglobins on electrophoresis at alkaline *p*H, and from the work of Hunt and Ingram[3,4], it is clear that the substituted chains of S and C carry a much stronger positive charge than the characteristic chain of hæmoglobin F, and one might expect their combination with the characteristic P chain to be unstable

We wish to thank Dr A E Mourant and Dr V M Ingram for helpful discussion

β-GLOBULIN ALLELES IN SOME ZEBU CATTLE

By G C ASHTON

National Cattle Breeding Station, Commonwealth Scientific and Industrial Research Organization Laboratory, Rockhampton, Queensland

THREE β-globulin alleles (β^A, β^D and β^E) have been described so far in British breeds of cattle[1] Two further alleles have now been recognized in zebu (*Bos indicus*) breeds It is proposed to call these alleles β^B and β^F

In most mammals the β-globulin alleles give rise to more than one zone by starch-gel electrophoresis[2] Each of the cattle β-globulin alleles β^A, β^D and β^E gives four detectable zones, the most rapidly migrating zone staining faintly with nigrosine, the next staining moderately and the slowest two zones staining intensely The two further alleles which have been detected also give rise to four similarly staining zones The relative mobilities of the groups of four

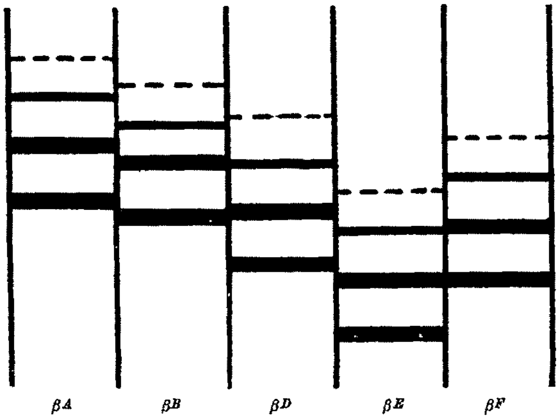

Fig 1 Relative mobility in starch-gel of the four zones produced by each β-globulin allele in cattle The anodic side of the gel is at the top of the diagram, only the β-globulin zones being shown

zones controlled by the five alleles are shown in Fig 1 It will be seen that the zones controlled by β^B are intermediate in mobility to those produced by β^A and β^D, while β^F gives rise to zones intermediate in mobility between those produced by β^D and β^E

Previous experience has shown that each β-globulin genotype formed from the alleles β^A, β^D and β^E gives only one phenotype[1] Fifteen phenotypes would therefore be expected from five alleles, fourteen have been found so far The homozygote of the infrequent allele β^B has not yet been seen The appearance of the phenotypes (Fig 2) was anticipated in the main from the knowledge that the pattern given by a heterozygote is indistinguishable from that given by a simple mixture of the corresponding homozygous sera[1,2]

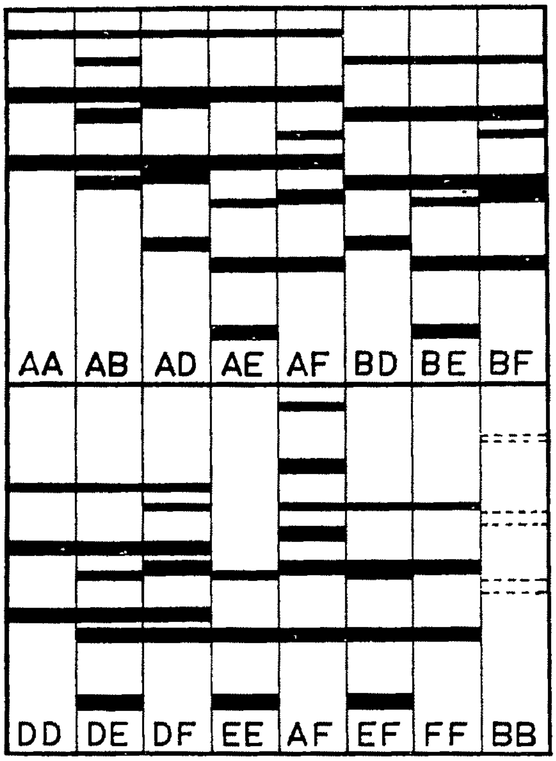

Fig 2 The fourteen cattle β-globulin phenotypes The anodic side of the gel is at the top of each portion of the diagram, only the β-globulin zones being shown The fast-moving faint band produced by each allele (cf Fig 1) is not shown For *AA AB*, etc , read β^{AA}, β^{AB}, etc The dotted zones for β^{BB} (bottom right) show the expected appearance of this phenotype, which has not yet been found

Data from matings between Sindhi × Sindhi, Sahiwal × Sahiwal, Sindhi × Jersey and Sahiwal × Jersey cattle confirm that the previously unrecognized phenotypes represent individual genotypes formed from five alleles (Table 1)

* Approximate frequencies computed from remainder of data

It has been suggested previously[1,3] that the frequency of β^E within a breed may reflect the climatic or ecological stress to which the breed is subjected Thus, the frequency of β^E increases in a northerly direction in the British Isles, both within and between breeds The high frequency of β^E in all the zebu breeds examined is particularly interesting therefore in view of the well-known climatic and ecological tolerance of these cattle

I thank the Officer-in-Charge of the F D McMaster Field Station of the Commonwealth Scientific and Industrial Research Organization, Badgery's Creek, New South Wales, and of the National Cattle Breeding Station of the Commonwealth Scientific and Industrial Research Organization, 'Belmont', Rockhampton, Queensland, for supplying blood samples, and C. Bloomfield for technical assistance

FORTHCOMING EVENTS

(*Meeting marked with an asterisk * is open to the public*)

Monday, November 23

Royal Geographical Society (at 1 Kensington Gore, London, S W 7), at 5 p m—Mr Barrie E Juniper "Oxford University Tanganyika Expedition"

Institution of Mechanical Engineers, Education Group (at 1 Birdcage Walk, Westminster, London, S W 1), at 6 p m—Discussion on "Vibration Theory, Linear Systems and the subject 'Theory of Machines'"

Tuesday, November 24

Society for Analytical Chemistry, Physical Methods Group (at the Chemical Society, Burlington House, Piccadilly, London, W 1), at 6 30 p m—Mr R A C Isbell "The Design of Optical Instruments for Chemical Analysis"

Royal Aeronautical Society (at 4 Hamilton Place, London, W 1), at 7 p m—Prof D B Spalding "Heat and Mass Transfer in Aeronautical Engineering"

Society of Instrument Technology (at Manson House, 26 Portland Place, London, W 1), at 7 p m—Mr N I Walker "Application of Instrumentation to Glass Melting Furnaces"

Radar and Electronics Association (at the Royal Society of Arts, John Adam Street, Adelphi, London, W C 2), at 7 30 p m—Prof H E M Barlow "Waveguides for Long Distance Communications" *

Wednesday, November 25

Royal Society of Arts (at St John Adam Street, Adelphi, London, W C 2), at 2 30 p m—Sir Christopher Hinton, K B E, F R S, and Sir William Holford "Power Production and Transmission in the Countryside—Preserving Amenities"

Geological Society of London (at Burlington House, Piccadilly, London, W 1), at 5 p m—Mr L R Raymond "The Pre-Permian Floor beneath Billingham, Co Durham", Dr J M Hancock "The Cretaceous System in Northern Ireland"

Institution of Electrical Engineers, Electronics and Communication Section (at Savoy Place, London, W C 2), at 5 30 p m—Dr R L Smith-Rose "Radio Aspects of the International Geophysical Year"

Institute of Physics (at 47 Belgrave Square, London, S W 1), at 6 p m—Mr J F Coales "Education for Automation"

Institution of Mechanical Engineers (at 1 Birdcage Walk, Westminster, London, S W 1), at 6 p m.—Prof A H Cottrell, F R S "The Effect of Nuclear Radiation on Engineering Materials" (Thomas Hawksley Lecture)

Society of Chemical Industry, Food Group (at 14 Belgrave Square, London, S W 1), at 6 15 p m—Mr G E Moss "Fortuitous Corrosion Inhibitor in Biscuit Mixes", Mr G P Seary "Recent Developments in Produce Pre-packaging"

Society for Analytical Chemistry (joint meeting with the Pharmaceutical Society of Great Britain, at 17 Bloomsbury Square, London, W C 1), at 7 30 p m—Meeting on "Methods of Assays of Capsicum, Lonchocarpus and Rauwolfia"

Thursday, November 26

Institute of Marine Engineers (joint meeting with the Society of Naval Architects and Marine Engineers, at the Memorial Building, 76 Mark Lane, London, E C 3), at 3 p m—Mr C C Pounder Human Problems in Marine Engineering", at 5 30 p m—Mr J Zrodowski and Mr H C Andersen "Co-ordinated Alignment of Line Shaft, Propulsion Gear and Turbines"

Institution of Electrical Engineers (at Savoy Place, London, W C 2), at 5 30 p m—Mr T R Manley, Mr K Rothwell and Mr W ray "The Application of Low-Pressure Resins to some High-Voltage Switchgear Designs"

Institution of Mechanical Engineers, Applied Mechanics Group (at 1 Birdcage Walk, Westminster, London, S W 1), at 6 p m—Discussion on "The Application of Creep Results to Engineering Design"

Royal Aeronautical Society (at Church House, Westminster, London, S W 1), at 6 p m—Prof H Schlichting "Some Developments in Boundary Layer Research in the Last Thirty Years" (Third anchester Memorial Lecture)

Thursday, November 26—Friday, November 27

Institute of Petroleum (joint meeting with the Corrosion Group and the Chemical Engineering Group of the Society of Chemical Industry, in the Grand Council Chamber, The Federation British Industries, 21 Tothill Street, London, S W 1), at 9 30 a m ily—Joint Symposium on "Corrosion Problems of the Petroleum Industry"

Friday, November 27

Royal Aeronautical Society (at 4 Hamilton Place, London, W 1), at 7 p m—Dr D R Walkie "Man and an Aero Engine"

Royal Institution (at 21 Albemarle Street, London, W 1), at p m—Dr P T Haskell "Research in the War against Locusts"

Friday, November 27—Saturday, November 28

Botanical Society of the British Isles (at the Lecture Hall, The British Academy, Burlington House, Piccadilly, London, W 1)—Darwinian Centenary Conference

British Society for Immunology (at the Wellcome Foundation, 183 Euston Road, London, N W 1)—Symposium on "Persistence of Immunity" Chairman Dr C H Andrewes

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Assistant Experimental Officers (2) (with a degree in agriculture or pure science with main subject zoology, or the Scottish Leaving Certificate (or equivalent) with passes in five subjects which must include English, Higher Mathematics and Science, and the ability to drive a car) in the Rodent Control Service, Department of Agriculture for Scotland—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S W 1, quoting Ref G388/9A (November 23)

Graduate Assistant (with appropriate professional qualifications and/or experience) in the College Library—The Principal, Royal Holloway College, Englefield Green, Surrey (November 27)

Assistant Lecturer or Demonstrator (with medical qualifications registrable in this country) in Pathology—The Registrar, The University, Manchester 13 (November 28)

Reader (with a degree in chemistry and a qualification in either pharmacy or a biological subject, a research degree and experience of direction of research in medicinal chemistry) in Medicinal Chemistry—The Clerk to the Governors, Chelsea College of Science and Technology, Manresa Road, London, S W 3 (November 28)

Senior Lecturer and a Lecturer (preferably with a major interest in applied thermodynamics or applied mechanics, especially the theory of machines) in Engineering—The Registrar, The University, Manchester 13 (November 28)

Assistant Lecturer (with special qualifications or interests in radio astronomy) in Physics—The Registrar, The University, Manchester 13 (November 30)

Lecturer in Organic Chemistry at the University of Melbourne, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (November 30)

Lecturer in Pathology in the School of Veterinary Medicine—The Registrar, Trinity College, Dublin (November 30)

Lecturer or Senior Lecturer in Preventive Medicine at the University of New England, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (November 30)

Lecturer (preferably with teacher-training experience in West Africa or other tropical areas) in Educational Psychology, Nigerian College of Arts, Science and Technology—The Council for Overseas Colleges, 12 Lincoln's Inn Fields, London, W C 2 (November 30)

Lecturer (with a recognized degree in agriculture) in Agriculture—The Clerk to the Governors, Essex Institute of Agriculture, Writtle, near Chelmsford, Essex (November 30)

Research Assistant in the Department of Physics for work concerned with the fundamental study of electroluminescence and related processes in single crystal phosphors—The Registrar, The University, Hull (November 30)

Senior Lecturer (of good academic standing and with industrial and laboratory experience in electrical machinery and automatic control) in Electrical Engineering at the University of Adelaide, Australia—The Registrar, The University of Adelaide, Adelaide, South Australia (November 30)

Technical Officer (with a university degree or comparable qualification in physics or electrical engineering or other aprpoved subjects) in the Department of Physics—Dr F B Kipping, University Chemical Laboratory, Lensfield Road, Cambridge (December 2)

Lecturer (preferably with research interests in autocology and whole-plant physiology) in Botany at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (December 5)

Lecturer in Social Anthropology and a Lecturer in Rural Sociology in the Faculty of Economic and Social Studies—The Registrar, The University, Manchester (December 12)

Senior Lecturer or Lecturer in Physics, and a Senior Lecturer or Lecturer in Inorganic Chemistry at the University of Khartoum—The Registrar, University of Khartoum, c/o Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (December 15)

Lecturer (with an honours degree in psychology, a higher degree in psychology or equivalent qualifications) in Psychology at Canberra University College, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (Australia, January 11)

Imperial Chemical Industries Research Fellows in Bacteriology, Biochemistry, Biomolecular Structure, Botany (Plant Biochemistry and Biophysics), Chemical Engineering, Chemistry, Chemistry of Leather Manufacture, Chemotherapy, Colour Chemistry and Dyeing, Engineering (Civil, Electrical or Mechanical), Fuel and Refractories, Geology (including Geochemistry), Metallurgy, Mining (Selective Flotation and Geophysical Surveying), Pharmacology, Physics, Physiology, or Textile Industries (Chemistry of High Polymers (Keratin and Man-made fibres), Textile Technology and Textile Engineering)—The Registrar, The University, Leeds 2 (February 15)

Chemist, Scientific Officer (with an interest in animal nutrition), and Agronomists, one Senior Scientific Officer and one Scientific Officer (with an interest in pasture plant physiology, sociology and assessment in relation to the breeding of new varieties for lowland and upland conditions)—The Registrar, University College of Wales, Aberystwyth

LECTURER IN MATHEMATICS, and a LECTURER IN STATISTICS AND MATHEMATICS—The Registrar, Bradford Institute of Technology, Bradford 7

PHYSICIST (with several years experience with radioactive isotopes), for work upon isotopically labelled steroids—The Director, Endocrine Unit, Institute of Obstetrics and Gynæcology, Chelsea Hospital for Women, Dovehouse Street, London, S W 3

PLANT PHYSIOLOGIST (honours graduate with research experience) IN THE DEPARTMENT OF SCIENTIFIC AND INDUSTRIAL RESEARCH, Palmerston North, New Zealand, to undertake research into the biochemical aspects of the physiology of plant growth and development under controlled climate conditions—The High Commissioner for New Zealand, 415 Strand, London, W C 2, quoting Ref No B 11/21/13, and mentioning *Nature*

RESEARCH ASSISTANTS (honours graduates in chemistry), to carry out research work for higher degrees in one of the following (1) the relationship between sorption affinity of alumina for a series of organic solutes in non-polar solvents and certain physical properties of the sorptives or (2) a problem in nitrogen heterocyclic chemistry—The Principal, Derby and District College of Technology, Kedleston Road, Derby

RESEARCH DEMONSTRATORS and RESEARCH STUDENTS IN THE DEPARTMENTS OF BUILDING AND CIVIL ENGINEERING, CHEMISTRY AND APPLIED CHEMISTRY, ELECTRICAL ENGINEERING, LIBERAL STUDIES, MATHEMATICS, MECHANICAL ENGINEERING, and PURE AND APPLIED PHYSICS—The Registrar, Royal Technical College, Salford 5, Lancs

SENIOR TECHNICIAN IN THE MICROBIOLOGICAL LABORATORIES—The Secretary, The Royal College of Science and Technology, George Street, Glasgow, C 1

TECHNICIAN IN THE DEPARTMENT OF BOTANY—The Registrar, University College of Wales, Aberystwyth

GENERAL EDUCATION IN A MODERN DEMOCRACY

IN his presidential address to the British Association at York on September 2, Sir James Gray pleaded strongly for a wider outlook in the teaching of science and stressed the need for a considered judgment as to the proportion of our total educational effort which should be devoted to the training of scientists and technicians—upon whom we depend for maintaining or extending our standard of living—and the proportion which should be expended on raising the intellectual standards whereby the bulk of the population forms its judgments on matters which are susceptible to personal prejudice or political propaganda Sir James recognized the implications of Dr Trenaman's inquiry into the impact of the mass media and maintained that the key to the problem lies in the schools The responsibility resting on secondary school teachers is not easily exaggerated, and Sir James pointed out that really inspired teachers, working with adequate but simple equipment, would achieve far more for general education than specialists in highly equipped laboratories

In the concluding part of his address, Sir James Gray referred to the possible contribution which the British Association might make to the problem of general education so far as science is concerned, and the attention given to this question was a feature of the York meeting Apart from this, no fewer than three of the presidential addresses to Sections of the Association discussed general or particular aspects of the main problem raised by Sir James A provocative address by Prof J Jewkes to Section F (Economics), for example, examined the question of balance between general education of the population in science and that devoted to the training of scientists and technologists In Section L (Education), Sir James Robertson raised much the same issue in frankly discussing the purpose of our educational effort, while, addressing the Assembly of Corresponding Societies, the Countess of Albemarle discussed the question how the ordinary citizen could prepare himself or herself to live intelligently in a scientific age, and the sources of information and instruction available for that purpose.

The Countess of Albemarle suggested that there are three essential needs for the ordinary citizen awareness of the character of the times in which he lives , some understanding of the methods of scientific research , and some readiness or determination to keep abreast of scientific development and invention As Sir James Gray had already pointed out—and as Dr Trenaman's inquiry shows—the attempt to meet these needs must begin in the schools, and there were other papers read at York which were equally concerned with the way in which this should be done Mr J Maitland, in Section J (Psychology), considered specifically the communication of science to the layman, Mr N F Newbury dealt with the place of science in the primary school before Section L and, before the same Section, Dr K Laybourn, in discussing the training of teachers of science and mathematics and what the schools require, laid his own emphasis on the importance of quality and the decisive contribution which an outstanding or inspired teacher in love with his subject and his job could make

It is, however, instructive to examine some of these fundamental issues debated at York in the light of the Clayton Memorial Lecture which Sir John Wolfenden delivered to the Manchester Literary and Philosophical Society in 1958 He did not attempt a definition of education, but pointed out that it is an essential part of a teacher's duty to instruct his pupils in certain areas of human knowledge and skill This responsibility for instruction is inescapable, and it is obvious that such instruction is what is in the minds of those who raised these issues at York Sir John, however, emphasized that education is, among other things, the influence of one personality on another That has been clearly recognized in the great schools and universities of Britain It is implicit in the comments made at York as to the importance and influence of the great and inspiring teacher

Sir John Wolfenden in this lecture proceeded to discuss some of the implications arising from this influence of the teacher upon immature minds, and much of what he said is important not only in the present context but also in that of the proposal recently advanced for giving votes to young people at eighteen years of age He faces frankly the difficulty of presenting truth objectively, particularly in relation to judgments of value, and no less he recognizes that the immaturity of the minds of our pupils is a fundamental difficulty Because of that immaturity, they are not capable of making up their minds for themselves when confronted with carefully balanced lists of credits and debits, and Sir John believes that of all the demands made on intelligent boys and girls nowadays, this is the one which causes the most unhappiness and strain It is not helpful to withdraw our experience and comparative maturity from them at this point.

Nor does Sir John believe that, in fact, it is possible to do so There is no neutrality in many such matters, and there is force in his suggestion that it may be as dishonest to pretend not to hold views which one does hold as to pretend to hold views one does not Moreover, the significant influence on the young is what a man is and does, not what he says, and what he is and does are inseparately fused with what he believes, with his convictions, principles and faith Tolerance and an open mind are indeed essential to human thought and progress, but they must be understood and practised as positives, not as negatives It is no part of real tolerance, Sir John reminds us, to believe that all opinions are equally valid, or of a genuinely open mind to be empty. Empty minds and closed minds are equally a reproach to the educator, and his final plea is not for preferential treatment for any one set of opinions or doctrines, but for a free, fair chance for all, accepting the risks involved where immature minds are concerned, because in this way we come nearest to being faithful to our immature pupils and to the truth itself.

Sir James Gray suggested that the value of an educational system can be judged by the extent to which it leaves people with a desire to know more about the world at large, and aware of the need—and the possibility—of satisfying this at least in part, by personal effort Obviously, too, a constantly changing environment involves a continuous review of the general pattern of teaching, but apart from this, it is a serious indictment of specialist training in science and technology that it so often leaves the specialist not merely with no knowledge of the humanities but also with no desire to attempt to make good the loss That of itself has not only destroyed the catholicity of intellect without which civilization cannot survive, but it has also contributed to make the scientist and the technologist the tools, first of commercial power, and later of the impersonal power of the State

This argument is developed by R T Rolt in an appreciation of the width of knowledge of I K Brunel with which he concludes his biography of that distinguished and versatile engineer, and his argument found echoes in a recent address of Sir Solly Zuckerman on science and freedom, as well as in Sir Charles Snow's thesis of the two cultures The divorce of the scientist and the engineer from the humanities involves a loss of proportion, and from that springs in some measure their loss of influence, while the door is opened to misunderstandings, doubts and fears which have both shaken man's confidence and weakened his control over events Sir James Gray wisely remarked that no young scientist should be allowed to forget that new discoveries tend to arise from the borderland between different subjects, where the discipline of one is applied to another, but that alone will not suffice. It would seem to follow from Dr Trenaman's study that this question of general education must be tackled in the schools, before specialization begins, if anything effective is to be done

Sir James Gray's address, no less than Sir John Wolfenden's, thus leads directly to the central question which Sir James Robertson discussed What are our schools for? It may still be a more open question than is often admitted, how much of our educational effort should be devoted to the training of professional scientists and technologists, and neither Sir James Gray nor Prof Jewkes denied that we might need to increase the present proportion What they did emphasize was that we should have due regard to the cost, and before we denied, in consequence, to a very much larger fraction of the community a reasonable chance of "seeing life steadily and as a whole", we should be sure, on the basis of impartial inquiry, that the need existed and that the cost is justified.

This question, however, cannot be entirely separated from that of the general education of the community If science is to be of direct cultural significance, it cannot, as Sir James Gray said, shut itself off from one of the main factors which have influenced men's attitude to social problems, and implicit in his address was a suggestion for further inquiry into the way in which scientists might receive this general education, possibly through the activities of the British Association itself If this inquiry supported a wider, and perhaps more biological outlook on general education, very far-reaching re-organization of both schools and universities might be involved, but this could scarcely be undertaken without giving a considered answer to the question, what are our schools for, if not to the corresponding question about the purpose of university education. Even to urge that science can only play its full part in furthering human welfare if it is used, at a very early stage of education, as a means of encouraging a dispassionate but optimistic attitude towards all aspects of human affairs, involves at least an answer to the first question.

Sir James Robertson's survey was largely inspired by the view that we are neglecting the greater task of education for the lesser, though not unimportant, task of instruction, and it should already be clear that many of our present shortcomings arise from this fact, perhaps in part, too, from a failure to realize that what ordinary children need most of all is neither this skill nor that smattering, but just to be humanized and helped even a little way towards civilized living It might well be urged that without this the scientist and technologist, too, are unlikely to contribute much towards meeting the real needs of mankind If, in fact, the main effort of the secondary modern school is diverted from the general education of the ordinary child, no improvements in the extent or quality of further education are likely to repair the damage It is abundantly clear already that the fundamental reason only a small minority of British adults continue their general education is not the lack of facilities but the defects in the education they have already received It is in the schools and the schools alone that the basis of a sound general education can be provided, either for the ordinary citizen or for the specialist

The whole trend of Prof Jewkes's address supports Sir James Robertson's conclusion that until we are content to accept children as they are, we will continue to lose the chance of developing the gifts they have, in our perverse determination to make them manifest powers which in fact they do not possess His second conclusion is endorsed by Sir James Gray's address: in its aims and emphasis our education should reflect, as it does not at present, the inescapable truth that it is for most of us relatively easy to get a job and do it decently, but tragically hard to be good human beings in our communities, our homes and our solitariness It will not be easy to change the emphasis from vocational training to education for life, nor perhaps even possible without a change of heart, but until it is done we can scarcely approach the problem of living with science and the effective use of the spoken or the written word and the visual image

To set Sir James Robertson's plea that the ordinary child needs to be humanized and to be helped towards civilized living against Sir John Wolfenden's plea that it is not helpful to withdraw our experience and comparative maturity from our pupils when they are faced with judgments of value, sufficiently illustrates how much common ground exists in these two approaches and how much depends on the teacher That remains the key problem, and especially how men and women of the right type are to be found and produced Even if the need for Britain to produce more highly qualified scientists and technologists is fully established, the development of general education for the ordinary citizen may still remain the more urgent problem for at least two reasons The production of scientists and technologists of the required qualities is linked with this problem of general education in the schools and the supply of appropriate teachers Moreover, since the general citizen, as the Countess of Albemarle observed, needs increasingly to have some understanding of what science is about, because decisions in public affairs nowadays usually in some measure and at some point involve an assessment of scientific and technical data, the appropriate measures to increase the supply of teachers—and in turn of scientists and technologists—depend very largely on the existence of an informed opinion capable of understanding the action required, and capable of supporting it until it has been carried to a satisfactory conclusion

RESEARCH IN GAS DYNAMICS

Fundamentals of Gas Dynamics

Edited by Howard W Emmons (High Speed Aerodynamics and Jet Propulsion, Vol 3) Pp xiii+749 (London Oxford University Press, 1958) 140*s* net

THE third volume in the Princeton series, "High Speed Aerodynamics and Jet Propulsion", is concerned with the fundamentals of gas dynamics In his preface the editor of the volume describes gas dynamics as a rapidly developing branch of physics and applied mathematics Tsien's introductory chapter, a general development of the equations of gas dynamics but dealing principally with the fluid mechanics of a continuum, amply illustrates the importance of applied mathematics in this field of study All possible combinations of compressible flows, adiabatic or diabatic, irrotational or rotational, steady or unsteady, are considered The last chapter on the flow of rarefied gases, by Schaaf and Chambré, defines clearly the regimes of gas dynamics, develops equations for free-molecule and slip flows and presents experimental data for the slip flow and transition regimes This chapter emphasizes that a broad knowledge of physics is required by a worker in the field of high-speed aerodynamics

Yet any engineer concerned with problems in gas dynamics will question whether Emmons's definition is complete, for while the need for a background in mathematics and physics will be agreed, the development of any branch of fluid mechanics as complex as this one must depend upon verification of analytical work in engineering experiments Crocco's chapter on one-dimensional flow (a 'book' of three hundred pages in itself) supplies a logical analytical development but shows an awareness of this need for experimental data It is surprising that some of the now classical descriptions of one-dimensional compressible flows (for example, the flows in ducts with friction and heat transfer under varying pressure ratios) have not been backed by a great deal of experimental work But Crocco has gathered together some excellent photographs of shock phenomena and presents the results of experiments that this reviewer has not seen before, particularly the work of Frossel. Some interesting experimental data obtained by Neumann and Lustwerk for the 'pseudo-shock' (the complex oblique shock wave pattern with turbulent mixing, which occurs when the boundary layers are thick) are also included, together with a review of the work of Shapiro and his associates on the 'aerothermopressor', a device in which the stagnation pressure of a compressible fluid flow may be increased due to the abstraction of heat (by injection and evaporation of water droplets)

Hayes's chapter on shock waves and gas dynamic discontinuities and that on shock wave interaction by Polachek and Seeger are well written and logically developed (This latter chapter contains some beautiful photographs of regular and Mach reflexions and intersections and of shock refractions) Stever's article on condensation phenomena, again interesting and readable, appears somewhat out of place in a volume in this series, for much of the material deals with steam flows Kantrowitz's chapter on unsteady gas dynamics appears to be a little brief to this reader, a non-specialist in the field, who found the brevity of the last article on the application of pressure waves in heat engines disappointing, especially as the quoted references on this subject are difficult to obtain (There are numerous references elsewhere in the volume to papers produced 'internally' by laboratories This growing practice of referring to unpublished work is to be deplored) Emmons's own individual contribution to the book, on flow discontinuities associated with combustion, is a lucid piece of writing, although the difference in notation between this section and the introduction on general aspects of combustion, by von Kármán, is a little confusing Sir Geoffrey Taylor, with assistance from R S Tankin, provides a section on the Chapman–Jouguet theory of detonation

One surprising omission is the lack of a chapter on the flow of real gases at high temperatures (that is to say, dissociated or ionized gases), although Crocco includes articles on the flow of gases with variable specific heats and gases obeying van der Waals's equation

Most workers in the field of gas dynamics will wish to know how this book compares with Shapiro's volumes on compressible flow, published in 1953, but the comparison is a difficult one to make for Shapiro's book is largely devoted to the teaching of gas dynamics The present volume is aimed at reviewing the state of research in gas dynamics, and will be widely used by specialist research workers in different fields

If any criticism may be made of the new volume, it is the usual criticism of a book by several authors—that of duplication of content material and differing notation (For example, the work by Hawthorne and Cohen, on the effect of heating and cooling a compressible flow, appears in three places) In general the book is of the high calibre expected of the distinguished authors and editor, and all physicists, mathematicians and engineers working in the field will be grateful for the publication of this volume

J H HORLOCK

MICROSCOPES AND PHOTOMICROGRAPHY

The Practical Use of the Microscope

Including Photomicrography By George Herbert Needham Pp xxiv+493 (Springfield, Ill Charles C Thomas, Oxford Blackwell Scientific Publications, 1958) 117*s* 6*d*

Photomicrography

By Dr Roy M Allen Second edition Pp xiii+441 (54 plates) (Princeton, N J D Van Nostrand Company, Inc , London D Van Nostrand Company, Ltd , 1958) 67*s* 6*d*

Applied Microscopy and Photomicrography

By H M Malies Pp 143+12 plates (London Fountain Press, 1959) 22*s* 6*d* net

IN many branches of scientific work the need to take photomicrographs arises both for record purposes and to illustrate lectures and published works It is generally accepted that success in photomicrography primarily depends upon a thorough knowledge of microscopical principles and the correct use of the microscope , it is with this that the book by G H Needham is more concerned From a study of the list of contents, it would seem that in scope and breadth of treatment this would be a most valuable book , unfortunately this does not prove to be the case, for here is one book which definitely cannot be recommended The treatment is unjustifiably dogmatic, and much of the matter is obsolete, for example, the chapter on electron microscopy, which only makes a passing reference to the technique of thin-sectioning Other valuable modern techniques such as phase-contrast and interference microscopy receive only a sketchy treatment

Although the book is profusely illustrated, it is felt that many of the photographs, particularly those of microscopes, are superfluous The essential features in a chapter on binocular microscopes, for example, are certainly not photographs of the stands, but diagrams which give the reader valuable information on, say, the arrangement of the prism trains and path of the light rays It is these features which are conspicuous by their absence The book has not even the merit of correct English or clear explanation to commend it The glossary of microscopical terms included in the book may be taken as representative of the general standard thus it is stated that "there is no connection between the focal length of an objective and its working distance, except that they are directly proportional' ! It seems that there is still need for a comprehensive reference work on microscopy

The other two books may be recommended without reserve Dr Allen's well-known "Photomicrography" appears in a revised and enlarged edition which gives a straightforward account of the principles and practice of photomicrography, including a chapter on home-made equipment which should prove useful to the enthusiast who has not the resources of a fully equipped laboratory at his disposal There is also an adequate section on the purely photographic aspects which should prove valuable to many The book by H M Malies has the great advantage of a low price, but it may be said at once that one gets very good value for money as it gives a clear account of basic microscopical technique There are many good line illustrations and plates A minor shortcoming is the lack of detailed information on the photographic processes involved in the making of a photomicrograph ; I would have liked to see a section on the use of the 35-mm camera included, in view of the increasing popularity of this size of negative for much of the routine photomicrography carried out to-day

S BRADBURY

LOW-TEMPERATURE ENGINEERING

Cryogenic Engineering

By Russell B Scott Pp xi+368 (Princeton, N J D Van Nostrand Company, Inc , London D Van Nostrand Company, Ltd , 1959) 5 60 dollars , 42*s*

THE word 'cryogenic' has come into fashion during the past five years and is intended to embrace all practical applications of low temperatures (say below − 150° C) In fact, it connotes, at the present time, a more restricted field in which the main emphasis is on techniques for the liquefaction and handling of low-temperature rocket fuels and oxidants, and special apparatus for low-temperature research The main fields of industrial low-temperature application, namely, air separation and ethylene production, remain largely outside its orbit This emphasis is clear in Dr Scott's book and arises naturally from the fact that the work of the U S Bureau of Standards Cryogenic Laboratory at Boulder, Colorado, of which he is head, has concentrated on the new applications of very low temperatures

The book is exceptionally valuable because the author combines a masterly understanding of the theory of his subject with access to detailed information on the most modern techniques, which he freely imparts

The chapter on gas liquefaction is useful because of its comprehensiveness and its detailed treatment of heat-exchanger design Hydrogen and helium liquefaction feature largely Gas separation is intentionally given only token reference, but this is compensated for by a useful treatment of gas purification by adsorption

Low-temperature thermometry is covered comprehensively and lucidly, as one might expect from an exponent of the subject

The storage and piping of liquefied gases is discussed in great detail, both theoretically and practically It is probable that the material given will be adopted as the standard text for many years to come

The final chapters of the book contain a compilation of the properties of cryogenic fluids and structural materials at low temperatures, gathered and sifted with the full resources of the National Bureau of Standards

The book is well written, and contains an ample bibliography

G G HASELDEN

A NEW INTRODUCTION TO GEOLOGY

Basic Geology for Science and Engineering
By Prof E C Dapples Pp ix+609 (New York John Wiley and Sons, Inc , London Chapman and Hall, Ltd , 1959) 76s net

"BASIC Geology for Science and Engineering" is designed to introduce geology to those studying to become geologists, agronomists, or engineers. The scope is wide , except for palæontology, all branches of geology are touched on, although physical geology is given greatest attention More prominence than is usual in a book on general geological principles is given to the soil, a topic which is introduced early in the book and returned to repeatedly in different contexts Indeed, the arrangement of subject-matter throughout is cyclical in character, return being made to different aspects of the same point as knowledge of contiguous subjects is built up This system is intended to facilitate the assimilation of some of the more difficult ideas It is not altogether certain that it succeeds, although it sounds logical, but it is certain that the arrangement is not conducive to rapid reference This is a pity, because the volume contains an impressive amount of up-to-date information, much of which has not found its way into a geological text-book before, and which often seems likely to be of greater interest to the advanced student or even the specialist in need of a quick reminder than to the beginner to whom the book is primarily addressed

At the present time geological research is tending to develop an increasing quantitative bias "Basic Geology for Science and Engineering" will appeal to those who believe that this is an inevitable and desirable change The approach to the subject is essentially analytical, and frequent recourse is made to empirical relationships and the theories and principles of physical chemistry and thermodynamics in introducing and explaining geological processes This approach has the merit that it uses points of view and processes of thought familiar to those whose interest in geology is a by-product of a more fundamental interest in some branch of engineering or other technology

There are those, however, who consider that the variables involved in geological processes are so many and so little understood that we are very far from being in a position to rationalize the subject along rigid mathematical lines—if it will ever be possible to do so Without taking the extremist view that all attempts to introduce quantitative concepts into geology are therefore a waste of time if not actually subversive, there does seem to be a danger that the newcomer to geology may be left with a misleading impression of simplicity, order, and exactitude if he is introduced to the subject by means of a series of mathematical equations Prof Dapples himself mentions the dangers of over-simplification, but he might well have given this point more emphasis One way of doing so would have been to stress the importance of work in the field, an aspect of geology which receives scant attention As a distinguished British geologist is fond of impressing on his students, the best geologist is the one who has seen the most rocks, and there is no doubt that familiarity with rocks, especially in the field, induces a healthily corrective scepticism towards glib generalizations, however elegant

So long as the limitations of the mathematical approach are borne in mind, "Basic Geology for Science and Engineering" will fulfil a useful purpose, but as an introductory text-book it will probably be of greater value to engineers than to those whose primary interest is geology.

The reading lists are compiled almost exclusively from North American sources

J C M TAYLOR

DIELECTRICS

Progress in Dielectrics
Vol 1 Edited by Dr J. B Birks and Dr J H Schulman Pp x + 312 (London Heywood and Co , Ltd , 1959) 70s net

THIS book is the first volume of a series which is intended to appear annually The present volume contains four reviews which cover fairly completely the recent advances concerning electric breakdown, two articles on ceramics and one on electrophoresis The editors appear to aim at the experimentalist with theoretical interests

The first article, on "Dielectric Breakdown in Solid Insulation", by J H Mason, brings up to date a subject last summarized by S Whitehead in 1951 The author assumes a knowledge of Whitehead's book and concentrates on recent work, in much of which he has played an active part The review is comprehensive and includes very recent work on electromechanical breakdown in plastics and thermal impulse breakdown in glass For the electrical engineer there is much practical information regarding breakdown by internal and surface discharges and electrochemical deterioration.

"Dielectric Breakdown Effects in Crystals" is very much the preserve of its reviewer, J. W Davisson The subject is essentially academic and involves both advanced theory and refined experimental techniques Davisson reviews recent work since Whitehead's book, and is careful to state fairly the conflicting views on controversial subjects, such as the theories of path formation

"The Electric Strength and High Field-Conductivity of Dielectric Liquids", reviewed by T J Lewis, is a very difficult subject, because much of the experimental material is contradictory The author, who has great experience in the field, does his best to explain the reasons for the discrepancies, but even so, the reader is left a little bewildered by the many sources of experimental error and the many alternative theories However, just in this kind of subject it is very helpful to have a critical review

The review of "Gaseous Dielectrics" by T W Liao and R E Plump is concerned not only with electric breakdown, but also with physical and chemical properties such as heat transfer and flammability It is a merit of this review that it treats physical and chemical considerations with equal interest, and that it brings out the general principles of its subject in an easily intelligible way The article contains also a number of useful practical considerations

The article on "Ferroelectricity of Barium Titanate Crystals" by A D Franklin is perhaps not quite as useful as the others because its subject cannot easily be separated from ferroelectricity in general, a subject which has been widely reviewed recently, both from the crystallographic and electrical point of view In the circumstances it might have been better if the article were more chemical and technological than it is, even though there are some useful references to chemical preparation

"Non-oxide Ceramic Dielectrics" by P Popper would seem to contain rather too much theory which is not immediately relevant However, it is useful to have information on this interesting new subject by an author who is actively engaged in research on it

"Electrophoretic Deposition of Insulating Materials", reviewed by J B Birks, is a practical subject which involves much chemical 'feel'. The author succeeds in presenting the relevant theoretical background of his subjects clearly and concisely, which is useful since colloid science is generally treated in a biological context The article gives a helpful survey of the practical applications

V. Daniel

EMBRYOLOGY

A History of Embryology

By Dr. Joseph Needham Second edition, revised with the assistance of Dr Arthur Hughes Pp 304+18 plates (Cambridge At the University Press, 1959) 52*s* 6*d* net

THIS new edition of Dr Needham's remarkable contribution to the history of science will be widely welcomed Its first appeal is to professional biologists, who will (or should) want to know more about the way their own science found its way out of abysmal ignorance and superstition towards greater knowledge and understanding, and historians of science will find it an indispensable source-book

But it is important for wider reasons It is important for the general historian, who will find in it numerous illustrations of the social relations of science One that I found illuminating was the fact that in the seventeenth and eighteenth centuries there was a widely held conviction (abundantly justified by later events) that research into the nature of generation would throw light on orthodox theological doctrines, such as that of 'original sin', and that this "led to an economic situation of value for biological development" To-day it is devoutly to be wished that the powers that be, including public opinion in general, would extend this conviction and realize that research in biology will throw light on the central problem of man's nature and destiny

The historian will also find many examples of the unfortunate political and social results of wrong attitudes to science and technology, for example, the contempt of antiquity for the 'base mechanic' and his arts, and the recurrent incomprehension of science and scientific method by governments and dominant classes As Sir Charles Snow has so pithily pointed out in his recent Rede Lecture this incomprehension between the professional scientists and the representatives and products of so-called humane studies can be mutual, and in Britain has led to the development of two cultures within the one nation

It would seem that the only way to heal this split is through some reform of education, aimed at the integration of the sciences and the humanities in the cultural process, and many of us feel that for this the historico-evolutionary approach is necessary

The evolutionary concept links man with the rest of life, mind with matter, contemporary history with archæology, while the history of science and its gradual invasion of new fields can be the bridge between the scientific and other elements in human history. Books like Dr Needham's are of the greatest value in helping to realize this process of our cultural re-education and re-integration

Julian Huxley

FOURIER SERIES

Trigonometric Series

By Prof. A Zygmund. Second edition Vol 1 pp xii+383 Vol 2. pp vii+354 (Cambridge At the University Press, 1959) 84*s* net each volume

ZYGMUND'S authoritative treatise, which first appeared as a single volume in 1935, has been thoroughly revised and much enlarged for this second edition The first volume contains practically everything which was in the original edition The essential foundations on convergence and summability are dealt with in the earlier chapters, the reader needs a firm grasp of the elements of point-set theory and of Lebesgue integration The main results are illustrated in a good chapter on special Fourier series The rest of the first and the whole of the second volume deal with special problems and topics, much of the material in the second volume being work done during the past thirty years, showing, in particular, the influence of Littlewood and Paley Each chapter is closely packed, and only the very indolent will ignore the additional wealth of content available in the annotated exercises

The author marshals his material skilfully A good example is his chapter on interpolation of linear operations, where the Riesz–Thorin interpolation theorem and the famous Riesz–Fischer, Hausdorff–Young and Riesz theorems which interpret and generalize the Parseval formula

$$\frac{1}{2\pi}\int_0^{2\pi}|f|^2dt = \Sigma|c_n|^2$$

for a function f with Fourier coefficients c_n, are neatly stitched together and embroidered with Paley's remarkable theorem on Fourier coefficients and the Hardy–Littlewood theorems on re-arrangement of Fourier coefficients His chapter on multiple Fourier series emphasizes the need for significant rather than obvious generalizations

Even where the ground has been well ploughed, some problems remain For example, it is now more than eighty years since du Bois-Reymond constructed a continuous function with a Fourier series diverging at one point, the extension to divergence at an everywhere-dense set of points followed easily enough, but so far all such sets have been of zero measure The question still stands Can a continuous function have a Fourier series which diverges at all points of a set of positive measure? A similar problem was solved some thirty years ago by Kolmogorov, with a delicate argument producing an integrable function with a Fourier series diverging everywhere

In its new form, beautifully produced by the Cambridge University Press, this book remains the standard and indispensable text for any analyst interested in Fourier series for their own fascinating sake

T. A. A Broadbent

Beitrage zur Neotropischen Fauna

Herausgegeben von Prof Dr Erich Titschack und Dr Hans-Wilhelm Koepcke 1 Band, Heft 3 Zur Kenntnis der Pseudoscorpioniden-Fauna des Andengebietes Von Max Beier Pp 185–228 Kritische Untersuchungen der Newportia-Arten Von Wolfgang Bucherl Pp 229–242 Ein neuer *Asthenes* (Aves, Furnariidae) von der Kuste und dem westlichen Andenabhang Sudperus Von Maria Koepcke Pp 243–248 Beitrage zur Kenntnis der Fische Perus II Von Hans-Wilhelm Koepcke Pp 249–268 (Jena · Gustav Fischer Verlag, 1959) 10 95 D M

THE first two papers in the above collection which continues this important new publication are of considerable interest to students of the multitudinous neotropical invertebrate fauna Dr Beier deals with a rich collection of pseudoscorpions from isolated regions of the Andes, especially Peru This region appears to be the developmental centre of genera like *Stenolpium* and *Parawithius*, while in Chile the nearctic genera like *Dinocheirus* fade out There are many endemic species here, and Dr Beier has found it necessary to make several new genera, all of which appear to be soundly based Whether the Pseudoscorpions show replacement of species by altitude is difficult to determine this is shown by such animals as some of the Chilopods, but unfortunately few of Beier's specimens have altitude data with them The new genus *Teratolpium* is found at high altitudes only, but conversely *Pachyolpium granulatum* Beier is found from 700 to 1,630 metres It is to be wished that, where a choice was available, the type specimen chosen should have been one from a known altitude (cf *Progarypus peruanus* Beier) Problems for future investigation may be glimpsed here and there, for example, *Lamprochernes*, a genus of world-wide distribution, has a species high up in the Andes, while *Apolpium vastum* Beier has been found only on orchids Bucherl's very important revision of the Scolopendromorph genus of Centipedes, *Newportia*, places the systematics of this group on a satisfactory basis for the first time The three subgenera *Newportides*, *Scolopendrides* and *Newportia* had been used or not by previous authors almost according to taste or fancy Bucherl shows quite conclusively that they apply to well-marked groups of distinct geographical range A really workable key covers all the known species and sub-species and entails several changes of attribution and status F A TURK

Crushing and Grinding

A Bibliography Pp ix+425 (London H M Stationery Office, 1958 Published for the Department of Scientific and Industrial Research) 35*s* net

THIS bibliography will be invaluable to the very many industrial users of the processes of crushing and grinding and to research workers interested in comminution, particle size determination and particle classification The bibliography proper is preceded by short authoritative reviews on fundamental aspects of crushing and grinding, problems of breakage and structure of coal, methods of particle size analysis, industrial grinding; crushing and grinding in the ceramic industry, grinding in the cement industry, crushing and grinding of minerals, grinding in the field of dyestuffs and organic chemicals, fire and explosion hazards in crushing and grinding operations The sections into which the bibliography itself is divided (with the number of references in each section shown in brackets) are fundamental aspects (450), crushing and grinding practice (354), coarse reduction (154), fine reduction (579), non-mechanical methods (63), materials (744); methods of particle size and surface area determinations (186), classification (160), dust and fire hazards (141) Nearly every reference is accompanied by a useful abstract There is a name index and a comprehensive subject index The Department of Scientific and Industrial Research and the small committee, under the chairmanship of Mr A S White, appointed to advise on the planning of the work, together with Mr W H Bickle, who undertook most of the detail of the work, are to be congratulated on this compilation This is the second bibliography published by the Department of Scientific and Industrial Research on unit operations—the first was on industrial drying (1951), it is to be hoped that further similar bibliographies will be produced S G WARD

River Pollution

1 Chemical Analysis By Dr Louis Klein Pp ix+206 (London Butterworths Scientific Publications, New York Academic Press, Inc, 1959) 30*s*, 3 50 dollars

THIS book is an expansion and revision of two chapters which appeared in an earlier work concerned with the general aspects of river pollution The pollution of the rivers of Britain has been widely discussed during recent years both in lay and scientific circles While it may well be true that "one photograph, particularly if it is in colour, may be worth a hundred dissolved oxygen samples in so far as securing public support or influencing a jury is concerned", the satisfactory resolution of the many problems involved can only be achieved after recourse to analytical methods

Dr Klein deals in this text with physical and chemical methods for the analysis of waters, sewage and trade wastes, biochemical methods are not considered The recent recommendations of the official "Methods of Chemical Analysis as applied to Sewage and Sewage Effluents" and the "Recommended Methods for the Analysis of Trade Effluents" prepared by the Joint Committee of the Association of British Chemical Manufacturers and the Society of Analytical Chemistry are incorporated No attempt is made to give detailed procedures but the many methods available are discussed critically and the most suitable method for a particular problem is indicated The bibliography contains nearly 600 references to the literature The appendix includes tables of saturation values for dissolved oxygen, conversion tables for various units of measurement, including degrees of hardness, tables of alkali conversion factors and various volumetric factors, and some typical analyses of waters and effluents

There seem to be few errors, one, common to many text-books, is that ferroin can be used as indicator in the dichromate-ferrous titration Unless an unusually high acid concentration is used the end-point is poor The book would be of greater practical importance had experimental detail been given for the more widely applied methods However, it should certainly prove a valuable guide to the literature of this important field R BELCHER

Bumblebees

By Dr John B Free and Dr Colin G. Butler With two appendices by Dr Ian H H Yarrow (The New Naturalist. a Survey of British Natural History) Pp xiv+208+25 plates (London William Collins, Sons and Co, Ltd, 1959) 25s net

IN their preface the editors express the hope that this book will widely encourage naturalists to take up the study of bumblebees, and it is indeed a stimulating work Much information is given in an easily understood form, and possible answers to problems as yet unsolved are suggested This eagerness to press forward on to untried ground does, however, occasionally lead the authors into making assumptions which are not entirely justified by the available experimental results Certain over-simplifications also occur in places, as, for example, on p 66 in the description of an experiment by Dr Free, which was designed to test whether bumblebees entering a strange colony can be recognized by their scent alone Reference to the original paper shows that the results were less clear-cut than stated here Nevertheless, in assessing the overall scope and value of the book these criticisms prove to be relatively unimportant

The development of colonies from their inception in the spring until the final hibernation of the mated young queens is described and, as in other chapters, the descriptions are illustrated by numerous original photographs Among other topics discussed are the division of labour, collection of food, recognition of intruders in the nest, and predators and parasites Not only are the biology and behaviour of bumblebees considered, however, for there is also an interesting chapter on their economic importance, in which their value as pollinators of crops and in plant-breeding is reviewed, various suggestions are also put forward for increasing their numbers in farming areas

Two appendixes by the authors on methods of collecting and rearing colonies contain much useful practical information, while a further two appendixes by Dr Ian Yarrow give a simple key to the British species of *Bombus* and *Psithyrus* and details of their distribution. M. Delia Allen

Foundations of Set Theory

By Prof Abraham A Fraenkel and Prof Yehoshua Bar-Hillel (Studies in Logic and the Foundations of Mathematics) Pp x+415 (Amsterdam North-Holland Publishing Company, 1958) 42 guilders, 84s.

Axiomatic Set Theory

By Prof Paul Bernays With a Historical Introduction by Prof. Abraham A Fraenkel (Studies in Logic and the Foundations of Mathematics) Pp. vii+226. (Amsterdam North-Holland Publishing Company, 1958) 45s

THESE two books are the latest in the series of Studies in Logic and the Foundations of Mathematics, produced by the North-Holland Publishing Co The first opens with a short chapter on the paradoxes of set theory and then proceeds to the axiomatic foundations, including the axiom of choice, the axiom systems of von Neumann, and of Bernays and Godel are discussed There is a chapter on type-theoretical approaches, containing developments by Quine, Wang, Lorenzen and others, and an interesting section on set theories based on non-standard logics Here, in particular, is a discussion of the rather obscure ideas of the Polish logicians, Leśniewski and Chwistek About seventy pages are devoted to intuitionistic conceptions of mathematics, and the bulk of the discussion concerns, of course, the ideas of Brouwer. The final chapter is concerned with metamathematics and semantics The bibliography, extending to fifty pages, covers comprehensively the years 1947–56, and will probably become the standard for this period

"Axiomatic Set Theory" is, apart from the introduction by Fraenkel, largely a presentation of a modified form of the material published by Bernays over the years 1937–54 in the *Journal of Symbolic Logic* It is a formal development and is carried out in detail in its applications to analysis, including the theory of real numbers, and to cardinal arithmetic The book is, as the author says, "designed for a reader who has some acquaintance with problems of axiomatics and with standard methods of mathematical logic"

To the 'working mathematician' these two volumes will indicate something of the great amount of effort which, in recent decades, has been expended in the field of symbolic logic and the foundations of mathematics The situation is still very fluid, and it appears that "the third foundational crisis that mathematics is still undergoing" is far from becoming a thing of the past L S Goddard

Elementary Statistical Physics

By Prof. C Kittel Pp ix+228 (New York John Wiley and Sons, Inc, London Chapman and Hall, Ltd, 1958) 64s net

THIS book contains a short but concentrated treatment of a wide field of theoretical physics Part 1 (116 pages) deals with classical and quantum statistical mechanics and its relation to thermodynamics, Part 2 (52 pages) with fluctuations, random processes in general (including the Wiener–Khinchine theorem), Brownian motion, noise and irreversible processes, and Part 3 (46 pages) with detailed balance, kinetic and transport theory. The three parts are divided into a total of 45 sections, many of which are preceded by references to standard works and recent papers

The exposition is usually clear and as simple as the topic permits, though there is an exception on p 19 where the law of increasing entropy is discussed before the entropy of a non-equilibrium state is defined The amount of application to particular problems is inevitably small in relation to basic theory Assemblies of non-interacting particles only are considered, except for an example on a linear ferromagnet in the section on the density matrix and an appendix proving the virial theorem of Clausius. However, where possible, the author discusses both knotty points and recent developments, as examples may be mentioned sections on the thermodynamics of magnetization and negative temperatures, respectively Problems are given, but some of these seem to be intended more as invitations to follow up the references than as exercises on the text For example, after no more formal definition of a Markoff process than the statement that the two-event probability function p_2 "contains all the information we need" the student is asked to prove the Smoluchowski (Chapman–Kolmogoroff) equation

The book may be recommended for readers who wish to find out about some of the great variety of problems and methods in modern statistical physics G M Bell

MYXOMATOSIS: PRESENT POSITION AND FUTURE PROSPECTS IN GREAT BRITAIN

By Dr. C. H. ANDREWES, F.R.S.
National Institute for Medical Research, Mill Hill, London, N.W.7

AND

H. V. THOMPSON and W. MANSI
Ministry of Agriculture, Fisheries and Food

SINCE the introduction of myxomatosis into Australia and its destruction of millions of rabbits, the situation there has fundamentally changed, and with a startling rapidity. The virus has become attenuated so that more rabbits survive; and still more important, natural selection has ensured that the present population of rabbits has a greater innate resistance to the disease. As a result of these two factors, myxomatosis is no longer regarded as of great value in keeping down the rabbits in Australia. Workers in that country[1,4] have studied the changes in the virus and in the rabbits in a most imaginative and painstaking manner, and in consequence we now have a fairly clear picture of developments there.

Course of events in Britain. In Britain, the history of myxomatosis appears to be following a rather different course. This is doubtless due mainly to the fact that the effective vector here is, for the most part, the rabbit flea (*Spilopsyllus cuniculi*), whereas in Australia mosquitoes are the principal vectors and *Spilopsyllus* is not present.

When the disease first spread in Britain in 1954–55 it did not sweep over the country but was gradually distributed in a patchy manner and the natural local spread was slow but effective: so effective that, by the end of 1955, the great majority (well over nine-tenths) of the wild rabbits had been killed by the disease. Of course, pockets of susceptible rabbits escaped infection and continued to breed, as did the animals recovering from infection.

There were few reports of myxomatosis in the first months of 1956, but what may be called secondary outbreaks were soon evident and, as shown in Table 1, have since appeared in many places. Curiously enough, the only English counties having little or no secondary myxomatosis have been in the west and south-west, whereas the only Welsh counties ever reporting secondary myxomatosis have been the five on the west coast. It was possible to say, in 1956, that there were no really heavy rabbit infestations on the mainland, but during the past three years rabbits have gradually increased, so that there are now considerable populations in some areas and damage to crops is more frequently reported.

Samples of myxoma virus collected in the field have been sent to Prof. F. Fenner at the Australian National University, Canberra, since October 1953 and two of these, sent in September 1954 from Sussex, were somewhat attenuated[1]. The first evidence of extensive infection with attenuated virus was in Sherwood Forest, Nottingham, in April 1955[2], and other cases have since been found in many areas (see Table 1). The British attenuated or atypical myxoma usually produces a nodular lesion with less diffuse œdema than in typical cases. During the early stages the nodules may contain fully virulent virus, but when they shrink and form scabs they contain virus of reduced virulence. By means of the gel diffusion precipitin test[3] cases of typical and atypical myxoma may be rapidly distinguished and the stage of the infection assessed.

Table 1. NUMBER OF COUNTIES IN ENGLAND AND WALES WITH OUTBREAKS OF MYXOMATOSIS

Year	Virulent disease	Attenuated disease	(No. of incidents)
1956	21	5	(24)
1957	36	10	(42)
1958	47	22	(106)

The connexion between the virulent and attenuated strains is at present by no means clear. In the Sherwood Forest area myxomatosis has persisted continuously since 1954 and both typical and atypical infections have been present since 1955. In the Edenbridge area of Kent, on the other hand, there was no secondary outbreak of disease from 1954 until March 1958, despite the marked increase in the rabbit population, although isolated cases of infection were found. In 1958 the Edenbridge rabbits were greatly reduced by disease which was typically virulent for the first four months, after which the presence of atypical infection was also demonstrated.

Changes in virulence of the virus. As Fenner and Marshall have shown, the attenuation of myxoma virus in Australia is a logical consequence of the relationships existing between virus, host and vector. A rabbit bitten by a mosquito which carries a relatively avirulent virus will survive longer than one infected with a more virulent strain and will, therefore, be able to serve longer as a reservoir of infection; virus will thus be carried by more mosquitoes to other rabbits. In Australia natural selection thus tends to favour an attenuated strain. In fact, fully virulent viruses deliberately introduced into areas where less vicious ones are already prevalent will dominate the scene for only a short time[4]; the less virulent ones supplant them in a matter of months. Virus which is too attenuated, however, causes lesions which apparently cannot serve as a good source for virus: so the tendency is towards domination by strains of intermediate virulence.

As already mentioned, attenuated myxoma virus has appeared in some areas of Britain and is on the increase, but modified strains have not, as in Australia, steadily ousted the highly lethal ones. After six years, the latter seem to be at least as numerous as milder ones. This might have been predicted from the nature of the virus–flea–rabbit relationship, which presents notable differences from the virus–mosquito–rabbit system in Australia. In contrast to the Australian situation, there is likely to be some evolutionary pressure in favour of a virulent virus. Fleas on rabbits infected with such a strain will naturally leave the rabbit when it dies and spread the highly lethal virus Where, however, a rabbit survives, the *Spilopsyllus* may have no occasion to seek a fresh host Even if the rabbit dies after a chronic illness, there may well be only a little virus on the flea's proboscis at that stage On a short-term basis survival of the highly lethal virus could thus be favoured Marshall and Fenner[5] have made suggestions on similar lines

This, however, can scarcely be the end of the story For, as Theobald Smith taught, a parasite which kills all its victims will soon perish for lack of fresh hosts to infect There will thus be a counteracting long-term tendency to perpetuate a not too virulent virus In practice there have been several instances where, at the beginning of a myxomatosis outbreak, highly lethal virus has been recovered, whereas in samples obtained later in the outbreak attenuated virus has predominated Rabbits with attenuated virus may be ill for a long time and the virus may persist in attenuated form by exchange of infected fleas in burrows The resultant of opposing evolutionary tendencies may well be a mixture of highly lethal and attenuated viruses existing side by side in the same locality Such a result could be brought about if the favoured virus were one which, as regards virulence, was genetically unstable , but what will in fact be the outcome, only time and alertness of investigators can reveal.

Changes in resistance of rabbits In Australia, a standard virus which originally killed 90 per cent of wild rabbits was only able, after the population had been exposed to seven successive epizootics, to kill 30 per cent of currently caught young ones[6] This tremendous increase in resistance seems to be of more practical importance than any change in the virus , and infection with myxomatosis has now become a minor factor in controlling Australian rabbits despite the fact that there is usually an epizootic each summer The British results summarized above do not suggest that any such change has occurred among our rabbits. One wonders, indeed, whether this would be expected in a population of hosts with an average life-span of about a year and with outbreaks of disease at irregular intervals which may, as around Edenbridge, be as long as four years

Discussion The main object of this article is to try to dispel the idea that myxomatosis here is bound to behave just as it does in Australia There is already good evidence that it is not doing so, and possible explanations of this have been brought forward We do not know how the virus persists between outbreaks and how it manages to re-appear after an apparent absence when rabbit numbers have materially increased It could conceivably persist in a modified form in an immune population or in some biting arthropod , but evidence is lacking that either method is actually possible over a period of years It could also be introduced on rabbit fleas temporarily carried on migrating birds, or on wind-dispersed, infected *Anopheles maculipennis* (= *A atroparvus*) since these mosquitoes are known to be vectors in southern England, though of minor importance compared with fleas Their role is believed to be rather greater in France, and if this is in fact so, myxomatosis there may have a different future from that in England. There remains the possibility of deliberate introduction by man, even though the Pests Act of 1954 made it an offence to use a rabbit infected with myxomatosis to spread disease among uninfected rabbits Few would deny that the indiscriminate spreading of the disease is undesirable, particularly in the absence of much more knowledge about the infection and the long-term consequences of its introduction In any event we must admit that we do not know which, if any, of the agencies discussed are adequate to account for the persistence of the disease and its re-appearance at times after a considerable absence

The increase in rabbit damage to crops in 1959 serves as a reminder that, despite myxomatosis, the rabbit population of Britain is again rising Much useful control has been possible by the concerted action of landholders through Rabbit Clearance Societies , there are now 370 of these, covering seven million acres of land or about 15 per cent of the agricultural area of Britain it would be most unwise to relax such efforts Above all, it is of tremendous importance for the future of farming in Britain that we should learn more of the natural history of myxomatosis and the factors making for changes in the virus and in the rabbits Myxomatosis provides an unusual opportunity to study and compare the evolution of a host–parasite relationship in the contrasting environments of countries at opposite ends of the Earth

INTERNATIONAL COUNCIL FOR THE EXPLORATION OF THE SEA

SPECIAL INTERNATIONAL GEOPHYSICAL YEAR MEETING

AS part of the oceanographic programme for the International Geophysical Year the onus of carrying out a Polar Front Survey in the North Atlantic Ocean was placed by the Comité Spécial de l'Année Géophysique Internationale (the body established by the International Council of Scientific Unions for the planning of International Geophysical Year operations) on the International Council for the Exploration of the Sea with the help of the International Commission for the Northwest Atlantic Fisheries A sub-committee of the International Council for the Exploration of the Sea under the chairmanship of Dr G Bohnecke (Federal Republic of Germany) co-ordinated the research plans of the different countries, and forty-six research and other ships of eleven nations took part in the survey At a meeting held under the chairmanship of Dr J B Tait (Britain) at the Council's headquarters in Copenhagen during October 1–3, 1959, 45 papers were presented dealing with the first results of the survey

About sixty attended the meeting, and Mr A J Lee and Dr D H Cushing (Britain) acted as reporters

Hydrography

The hydrographical papers were given in groups, according to geographical regions

Barents Sea The paper by Prof I Hela (Finland) described Finnish work at the beginning of the International Geophysical Year Various sections were worked and can be compared with those of the German research ship *Poseidon* in 1927 The temperature and salinity of the Atlantic water penetrating the Barents Sea were higher in 1957 than in 1927 An increase in salinity of 0 04 per mille on the standard values of all the basic water masses was observed , surface temperatures and salinities were higher than the average values given in the atlas by Dr Krauss Mr A J Lee showed that the volume transport of the West Spitsbergen Current was below normal taking the International Geophysical Year as a whole, and that temperatures in the south-eastern Barents Sea were subnormal He related this state to the abnormally strong development of the Polar high-pressure system and the southward displacement of the atmospheric Arctic Front Norwegian work in the area during various seasons was described in a paper by Mr L Midttun (Norway) which was read by title.

In the first of two papers on the chemistry of Barents Sea water, Dr S Gripenberg (Finland) found that the alkalinity/chlorinity ratio was higher in the Norwegian coastal water than in the Atlantic water or the East Spitsbergen Current, but that the reverse applied when the boron/chlorinity ratio was considered this implies that most of the boric acid is bound up in organic complexes In the second paper, Dr A Voipio (Finland) showed that different methods of analysis gave different results for the total iodine content of sea water and demonstrated how little we know about the iodine content of sea water

Greenland and Norwegian Seas Drs T I Gorshkova and E V Solyankin (U S S R) showed that the deposits on the sea-bed, by differing in their chemical composition, particularly in their content of carbonates and of iron and manganese oxides, are indicators of the hydrographic conditions prevailing in the basins of these two seas Dr J N Carruthers (Britain) pointed out the pioneer use by Otto Pettersson of this technique In a paper read by title, Dr G N Zaitsev *et al* (U S S R) have computed the water and heat budget of these seas When the various components are summed, the difference between the heat input and output amounts to only 0 4 per cent The authors then proceed to show the relative importance of these different components in different parts of the seas · advection of heat by currents is found to be the most important Finally, they have computed the nutrient salt budget Dr A P Alekseev *et al* (U S S R) described Russian hydrographic work in the southern part of the Norwegian Sea in 1958 In April the East Iceland Arctic Current was strong, blocking the inflow of Atlantic water to below average in October the inflow was intensified The waters near the bottom in this area were found to have a salinity of 34 87–34 88 per mille and the authors assumed that they are related to the East Iceland Arctic Current and flow from west to east It was pointed out by Mr O Sælen (Norway) that these salinity values are lower than the standard values for Norwegian Sea bottom water Dr J B Tait (Britain) pointed out that the water might have been Arctic Intermediate Water In reply to a question, Prof J V Preobragenski (U S S R) said that the salinities had been determined by the Knudsen titration method At this stage Prof G Dietrich (Federal Republic of Germany) stressed that the results collected during the Polar Front Survey should be sent to the International Council for the Exploration of the Sea as well as World Data Centres *A* and *B* Mr Sælen described Norwegian work in the same area in 1958, in March and October an intensification of the inflow of Atlantic water in the latter month was noted, as had been reported by the Russian workers A special feature observed was the ascent of cold water along the continental slope off Norway. Finally, Dr J Eggvin (Norway) presented a series of temperature, salinity and current charts for the Norwegian and Greenland Seas, and showed how the Norwegian Sea bottom water is formed in the region north of the Jan Mayen Ridge in some years and not in others, depending on the meteorological conditions, and how this bottom water flows southwards from the Greenland Sea along the foot of the Norwegian continental slope towards the Faroe–Iceland Ridge It was further shown that the temperature of the bottom water of the Greenland Sea increased in temperature northwards from the main area where it is formed This temperature increase is a result of mixing with Atlantic water The positive difference between the temperature of the bottom water of the Arctic Ocean and that of the Greenland Sea can therefore be explained without, as previously, assuming a submarine ridge (1,200–1,500 m) between Spitsbergen and the north-eastern part of Greenland This is of interest in view of the recent work of Dr. L Balakshin (U S S R), who by investigations on board ice-breakers has shown that the sill depth between the Greenland Sea and the Arctic Ocean exceeds 3,000 m In discussion of this paper it was pointed out that the sinking of water to form the bottom water might set up a system of compensatory surface currents which would be of importance to the Barents Sea fisheries

Shetland–Faroe–Iceland Region Dr J B Tait and Mr J H A Martin (Britain) had computed the volume transport through the Faroe–Shetland Channel over the period of the International Geophysical Year and found it to be high at the beginning and end but low at other times Gulf of Gibraltar water seems to have been present in the oceanic water-mass in June 1957 and June 1958 In June 1957 the inflow was cut into two parts by Arctic Intermediate Water which was moving southwards, and in June 1958 it was similarly divided by a southerly flow of Norwegian Sea water Overspill of cold Norwegian Sea water was noted along the Faroe–Iceland Ridge in June 1957 and March 1958 but not at other times

On the basis of surveys made along the Faroe–Iceland Ridge during 1957–58, Dr J H Steele (Britain) had come to the conclusion that overflow of very cold (0–2° C) water is rare and unimportant, but that there is continuous overflow of a slightly warmer

(2–4° C) water which is the product of mixing of water masses of Atlantic and Arctic types on the top of the ridge This overflow has a geostrophic motion north-westwards along the southern side of the ridge, and it then turns southwards along the eastern side of the Reykjanes Ridge The total flow over the ridge is calculated as being near the mean value of the Faroe–Shetland inflow A discussion of this paper by Prof Dietrich showed that, on about 50 per cent of the surveys of the ridge, overflow of cold (0–2° C) water has been found The relative importance of overflow directly across the ridge and outflow through the channel between Faroe and Faroe Bank was debated by Dr Tait, Mr F Hermann (Denmark) and Dr Carruthers

North Atlantic Ocean Prof Dietrich described various stages in the evolution of the International Geophysical Year and considered the next stage the exploitation of the observations He suggested the preparation of an atlas of maps and sections of the North Atlantic Using German observations, he demonstrated the existence of six water masses on the Cape Farewell–Flemish Cap section In particular, he examined the origin of the North Atlantic deep water in the Labrador Basin and the overflow of cold water across the Iceland–Greenland Ridge, and showed how the latter could be tracked over a great distance clinging to the lower part of the continental slope and not flowing along the very bottom of the basin He also showed how the winter surface isotherms are a guide to the circulation of the North Atlantic in that season.

A paper was given by Dr W Krauss (Federal Republic of Germany) showing that internal waves can be set up in the deep layers of the ocean as well as in the upper layers by the action of the wind

From dissolved oxygen/potential temperature diagrams, Dr L H N Cooper (Britain) concluded that the water column in the Bay of Biscay consists of a layered series of resident water masses resembling a pile of plates stacked one on the other He regarded these plates as being the result of the overspill of boluses of cold water across the Faroe–Iceland Ridge He also demonstrated a secular change in dissolved oxygen content since 1922 It was pointed out by Prof Dietrich that the stepwise structure described could also be explained by Dr Cooper's earlier turbidity current theory, and that this structure had not been as yet found in other areas where very detailed hydrographic observations had been made (for example, south-west of Iceland) The dating of the climatic fluctuation which had brought about the secular change in dissolved oxygen content was discussed by Mr Lee and Dr Cooper

French observations in the North Atlantic and Davis Strait were described by M G Peluchon (France) Charts of the currents in the region of 50° N showed the meandering of the current as it leaves the Grand Banks area and a decrease in the meanders as the current proceeds eastwards

Dr J Joseph (Federal Republic of Germany) described his work with a transparency meter combined with a thermocouple The turbidity distribution depends on local production on one hand and advective processes and turbulence on the other Connexions between the turbidity sections and the temperature sections could be seen He also showed that there is no change in turbidity at the deep scattering layer In discussion a strong case was made for fish as being the cause of this layer

Dr H Weidemann (Federal Republic of Germany) described work with towed electrodes (*GEK*) between Greenland and Iceland At a fixed station south of Iceland the records collected over a period of 30 hr allowed the relation between wind and surface current to be investigated The results gave a mean deflexion of current to the right of the wind of 27° and a current/wind ratio of 1 4–1 5 per cent The difference between these values and Ekman's theoretical values can be explained by assuming that conditions were non-stationary

Mr F Hermann described Danish observations in the North Atlantic in July–August 1958 West of the Reykjanes Ridge the basin was largely filled with sub-arctic mixed water, as already described by Prof Dietrich Cold water coming over the Iceland–Greenland Ridge was again found on the bottom in the western part of the Irminger Sea East of the Reykjanes Ridge a bottom layer with a temperature below 3° C was found, consisting of mixed water derived partly from overflow across the Faroe–Iceland Ridge, partly from Atlantic water and partly from sub-arctic water This water circulated anti-clockwise around the basin and crossed the Reykjanes Ridge to flow north on its westward side and mix with the overflow across the Iceland–Greenland Ridge In the Davis Strait water which had overflowed the Greenland–Baffin Island Ridge but which does not contribute to the North Atlantic circulation as a whole was detected

Dr R A Cox (Britain) gave an account of the work of R R S *Discovery II* A section showing the distribution of silicate along lat 24° N had three outstanding features the depletion of silicate but not of phosphate at the surface in the Sargasso Sea, the high silicate content of the bottom water of Antarctic origin west of the mid-Atlantic Ridge, and the very irregular bottom topography Work with Swallow's neutrally buoyant floats west of Portugal showed how even in the deep ocean there are great variations in current speed and direction The outflow of Mediterranean water from the Straits of Gibraltar had also been tracked by these floats, and it was shown that a westward movement of 12 nautical miles/day could exist close to the Spanish coast, but that farther south there were large eddies Dr Cooper pointed out that the silicate distribution along lat 24° N showed that Antarctic bottom water must make a contribution to the bottom waters east of the mid-Atlantic Ridge, and Prof T Braarud (Norway) did not think that the silicate deficiency prevented phytoplankton production in the Sargasso Sea The phosphate budget of the Mediterranean Sea was discussed by several speakers Mr Sælen then described Norwegian work carried out in collaboration with R R S *Discovery II* west of Portugal Current measurements from an anchored ship allowed the tidal streams to be analysed, they were present to the bottom (760 m) and showed no decrease in velocity with depth, but there were indications of some differences in the direction of rotation The residual current, however, decreased with depth

Prof N Menendez (Spain) gave an account of temperature and salinity conditions along the meridian of Tarifa in August 1958 Sections were worked at different states of the tide and the distributions found could only be explained in terms of changing mixing conditions depending on the strength of the tidal streams

Mr L V Worthington and Mr W G Metcalf (U S A) examined the salinity/potential temperature relationship in the North Atlantic deep water using the very precise salinity data that have now become available with the development of conductimetric techniques A salinity/potential temperature curve for the western North Atlantic below the 4° C potential isotherm has been established and its shape accounted for in terms of water masses Departures from this curve in different parts of the Atlantic can be used as indicators of water movement The outstanding features shown by this form of analysis were the formation of the newest Atlantic deep water in the Labrador Basin, the part played by the South-East Newfoundland Ridge in preventing the Antarctic bottom water from reaching the Labrador Basin, the water of the Norwegian Sea origin on the eastern slope of the mid-Atlantic Ridge, the outflow and spreading of Mediterranean water, and the fact that the western basin of the South Atlantic is the source of the deep cold water found in the rest of the Atlantic, communication to the eastern basin being through the Romanche Trench

A paper by Mr J R Lumby (U S A) read by Dr Tait showed that there were large differences in the dissolved oxygen values at comparable stations worked by American, British and Russian ships during the International Geophysical Year Mr Worthington said that such differences could depend to some extent on the type of water-bottle used, and on the method of standardization of the sodium thiosulphate solution used for titrating the samples

Baltic and North Seas In a paper on the southern Baltic Sea, Dr A Majewski (Poland) showed that the inflow of oceanic water had decreased since 1951–52 and that, at the end of 1958, the salinity in the Baltic basins had reached its lowest level since 1952 The year 1958 had been a cold one so far as the Baltic was concerned Similarly, in a paper on the North Sea by Dr J Filarski (Poland), read by title, the winter and spring of 1958 were shown to have been cold, but by the autumn of 1958 there were positive anomalies of temperature Dr V V Betin and Prof J V Preobragenski (U S S R) submitted a paper which was read by title on ice research in the Baltic during the International Geophysical Year Aircraft were used to make synoptic surveys of ice conditions The curves of accumulated temperature, ice extension and ice accretion so produced were found to be related

Biology

Prof E Steemann Nielsen (Denmark) presided over the biological session

Productivity Three papers were presented The first was by Mr Grim Berge (Norway) on the productivity of the Norwegian Sea using, besides carbon-14 measurements, an estimate of productive capacity, derived from measurements of transparency A continuously recording transparency meter was described It was shown that in 1958 the quantity of production as measured by 'productive capacity' was different from that in 1954 In reply to a question as to whether there was a correlation between productive capacity and standing stock, Mr Berge replied that there was, but that the relationship was different in different water masses Prof Braarud commented on the marked changes noticed from year to year and their apparent relation to hydrographic processes

Mr Vagn Hansen and Prof E Steemann Nielsen described carbon-14 measurements and chlorophyll measurements in the North Atlantic and in the Greenland Sea Mr Hansen showed that from Cape Farewell to Ireland greater counts of carbon-14 were obtained towards Greenland and above the Reykjanes Ridge This was associated with greater quantities of chlorophyll Prof Steemann Nielsen demonstrated the relationship between carbon-14 counts and quantities of chlorophyll *a*, which was biased by the possible presence of dead chlorophyll Mr G Murphy (U S A) asked whether transparency might not be a better method of measuring productivity if the constants in the equation were known Prof Steemann Nielsen replied that this would be a good method in oceanic waters, but in coastal waters the quantity of inorganic material was high Dr M Gillbricht (Federal Republic of Germany) pointed out that only one-third of the turbidity in the Irminger Sea was due to plankton Mr Berge said that the quantity of inorganic particles ordinarily was constant and so the variations due to production differences could be estimated

Biophysics and Biochemistry Dr H Schaefer (Federal Republic of Germany) described the distribution of amino-acids in redfish (*Sebastes*) and certain other fish for a number of stations at sea It was shown that the variation in relative composition of certain amino-acids was much greater than that which might have been expected from studies in freshwater fish Mr Murphy noted that a similar result had appeared in the work on the Californian sardine

Plankton Dr K F Wiborg (Norway) described the distribution of zooplankton in the Norwegian Sea He noticed that the distribution of reverberation on the echo-sounders at full gain corresponded fairly well with the distribution of euphausiids and fish fry The distribution of copepodite stages bore some relation to hydrographical conditions In response to a question, Dr Wiborg said that smaller fish have smaller eggs and spawn later

Drs E A Pawstiks and L N Grutzov (U S S R) presented a paper on the distribution of plankton in the Norwegian Sea This distribution corresponded reasonably well with that presented by Dr Wiborg

Dr J H Fraser (Britain) described indicator species in the Faroe–Iceland Ridge region and from the presence or absence of certain long-lived animals concluded that the International Geophysical Year was not a normal year Mr Lee pointed out that during the first eight months of 1958 the Polar Front lay well to the south, presumably holding back the northward flow of Atlantic water

Dr Gillbricht gave a detailed account of the distribution of phytoplankton, zooplankton and organic particles on a section between Newfoundland and the Azores Counts were made from small water samples of 0 3 ml for phytoplankton and of 5 ml for zooplankton By converting all quantities to total carbon and comparing these with phytoplankton, he was able to distinguish three water masses Prof Steemann Nielsen asked whether the organic particles were artefacts, because if the same technique is used in Danish waters many organic particles were derived from the destruction of phytoplankton Dr H Einarsson (Iceland) noticed that the quantity of zooplankton collected with Hardy indicators in the Irminger Sea was roughly similar to that collected with a 5-ml water sample in the same area

Mr J Corlett (Britain) described the zooplankton collected at weather stations *I* and *J* and showed that the total quantities were greater in 1958 than in 1957 Mr Hansen noticed that *Evadne nordmanni* had also been found in the Norwegian Sea. Dr Fraser said that *Thalia democratica* found by the Plankton Expedition in 1888 off west Scottish coasts appeared for the first time off west Scottish coasts in 1958

Dr W Hohnck (Federal Republic of Germany) presented an interesting paper on the quantity and types of fungi in the sea and on the sea bed The majority of samples taken showed development of hyphæ

Fisheries Dr Eggvin presented a paper by Mr L Midttun on echo-surveys in the Barents Sea In general, there was a relationship between the distribution of echo-traces and isotherms in the Barents Sea

Conclusions There appeared to be two main conclusions from the biological papers

(1) The International Geophysical Year differed in two respects from some other years, in indicator species and in quantity of living material

(2) Three advances in productivity studies were revealed (*a*) the use of transparency as an index of productivity under certain limited conditions, (*b*) the fairly close relationship between standing stock (as chlorophyll) and productivity (as carbon-14 count), (*c*) the use of very small samples of phytoplankton (0 3 ml) and zooplankton (5 ml) to give sensible estimates of carbon in living material

EFFECTS OF FOREST AREAS ON WATER RESOURCES, AND THE TECHNIQUE OF LYSIMETRY

BETWEEN September 8 and 13, two symposia were held in Germany by the International Association of Scientific Hydrology, at Hannoversch-Munden, where the Forestry School of the University of Gottingen is established

One symposium concerned the influence of wooded areas on the elements of the water balance Thirty-five papers were presented, ten from the U S S R , eight from the United States, four from Great Britain, two each from Finland and Poland and one each from the Belgian Congo, Czechoslovakia, Denmark, French Africa, Germany, Holland, Hungary, South Africa and Switzerland

The other symposium dealt with the technique of lysimetry and the causes of error in results obtained There were seventeen papers, four from the United States, three from Holland, two each from the Belgian Congo, Germany and the U S S R , and one each from Austria, France, Hungary and Great Britain

The papers were made available in printed form at the meeting and have since been placed on sale by the Association* Most of them are written in English, and the few others in French or German

The symposia were attended by more than a hundred hydrologists, from other countries as well as from those which contributed papers There was naturally a strong German representation, while both the United States and Great Britain had important teams It was regretted that, while the U S S R had sent several valuable papers, their authors were not present to introduce them

Below is given an appreciation of each of the two symposia and of a two-day visit paid afterwards to German field-stations concerned with one or other of the two subjects that had been discussed

It is expected that the discussions of the papers will be reported briefly in the quarterly issues of the Association's *Bulletin*, the price of which is 150 Belgian francs yearly

Water and Woodlands

In many countries, increasing concern with the provision and maintenance of adequate water supplies in the face of continuously increasing demands has stimulated considerable interest in the scientific management of this most vital of our natural resources With fuller appreciation of the importance of form of land use in catchment areas, much attention has naturally been directed to the role of a forest cover Compared with other countries such as the United States and Germany, Britain is a rather late entrant into this field, but within recent years, the problem has come very much to the fore and there can be no doubt, especially in view of the recent drought, that we shall have to devote very much more attention to this important issue As elsewhere, differences of opinion exist as to whether, from the hydrological point of view, our catchments are better under forest than, say, under pasture The answer is by no means as clear-cut as some would make out, the hydrological relationships involved are most complicated and objective quantitative assessments beset with considerable practical difficulties It was therefore most timely that under the auspices of the International Association of Scientific Hydrology much of the experience and present knowledge in this field could be surveyed and discussed

Almost half the contributions were concerned with investigations on the catchment scale In principle, these involve the measurement of precipitation and run-off (both surface and subsoil), normally by stream gauging, despite the substantial cost of installation and maintenance, and, very often, difficulties in ensuring absence of leaks and a reasonable standard of precision, this approach is still essential for the provision of the basic hydrological data appropriate to the problem as a whole As an alternative to the 'straightforward' comparison, say, between forested and non-forested catchments, Idson (U S S R) preferred continuous measurements on an area under the influence of a varying forest cover Because of the well-known difficulties in ensuring comparability between catchments, this latter approach would generally seem to be the more reliable one, the regression techniques used by Idson and by Anderson and Hobba (U S A), in which run-off is related to the various meteorological, soil or land-use factors which influence run-off, offer an approach which allows for a more complete interpretation of the complex relationships involved

---

* Publication No 48 (Vol 1 Water and Woodlands) Pp 340 300 Belgian francs Publication No 49 (Vol 2 Lysimeters) Pp 169 150 Belgian francs Obtainable from Mr Arthur F Bird, 66 Chandos Place, London, W C 2, or the Secretary of the International Association of Scientific Hydrology, Prof L J Tison, 61 Rue des Ronces, Gentbrugge, Belgium

In those countries where snow forms an important source of water there was general agreement as to the beneficial influence of a forest cover, the data of Anderson and Hobba (U S A), Goodell (U S A), Martinelli (U S A) and Sozykin (U S S R) clearly showed that through accumulation and the shelter provided, the forest retards thawing, reduces the danger of spring floods and prolongs the supply of melt water The difficulties of measuring snowfall and the need for further investigation were made clear in the papers of Martinelli (U S A) and Sepannen (Finland)

General recognition was also given to the higher permeability and greater storage capacities of soils developed under forest, leading to reduced surface run-off, less erosion and a more prolonged yield of water during drought Anderson and Hobba (U S A), Valek (Czechoslovakia) and Banky (Hungary), among others, clearly demonstrated the regulatory effect of the forest on stream flow, Rodier (French West Africa) showed that flood peaks were 8–12 times lower from forest than from savannah, and the importance of this effect was recognized by Wicht in his published recommendations for the management of catchment areas in South Africa

So far as absolute quantities were concerned, most contributors were prepared to accept a somewhat lower yield from a forested area as compared with areas under other vegetative covers Meginnis (U S A) provided one of the more extreme examples from the classical Coweeta experiments in North Carolina, where clear cutting of mountain hardwood forest increased the annual yield by 11–17 in and cutting of the shrubby understory by 2 in To conserve water in the south-western United States, Horton recommended the clearance of phreatophytes (vegetation with permanent access to ground water) along streams and rivers While such losses from forest stands were generally attributed to higher levels of transpiration, usually because of deeper rooting and access to water during dry periods, some would attempt to explain at least some of the losses to interception of precipitation by the foliage Thus, Eidmann (Germany) stated that because it intercepts appreciably less rainfall, a beech forest conserves more water than a spruce forest The implied assumption that intercepted water means a corresponding loss to the soil was contested by Leyton and Carlisle (Great Britain), who produced experimental evidence indicating, as might be expected, a marked fall in transpiration following wetting of the foliage, attention was also directed to the possibility of rather large errors in the estimation of through-fall in a stand using a limited number of gauges, and the increase in accuracy obtainable when these were replaced by troughs with larger collecting areas The papers of Bochkov and certain other Russian contributors provided an interesting contrast to the generally prevailing opinion that a forest cover means a lower yield of water These authors argued that, because of deep ground-water movement in forest soils, the gauging of small streams draining small catchments may under-estimate the yield and that over large areas, in certain cases at least, yield from the forest may be even higher than that from open land. Sokolovsky (U S S R) also claimed that an increased water loss from forest by transpiration may be balanced by reduced evaporation from the soil It is possible, therefore, that even in the case of water yield, final judgment on the effect of a forest cover may have to be postponed, from the point of view of energy relations, at least, one would not expect large differences in the loss of water from different types of vegetative cover

A number of contributors described other means of investigating quantitatively the hydrological relations of a site Visser (Holland) explained his soil moisture flow approach, which provides an estimate of the water balance from measurements of rainfall, potential evaporation and the ground-water level in the soil and in ditches, Lebedev (U S S R) also provided an interesting analysis of ground-water dynamics under forest and grass covers From measurements of water loss from detached shoots of Scots pine, Rutter (Great Britain) gave evidence of transpiration values apparently exceeding Penman's estimate of E_T (potential evaporation from grass), this, combined with his observations that the trees continued transpiring even down to a soil moisture deficit of 7 in or more, introduces still further problems in our interpretation of forest hydrological relationships As yet another approach to the estimation of water losses from forest stands, Leyton (Great Britain) discussed the possibility of measuring the volume rate of sap flow in tree stems by the heat-pulse method originally introduced by Huber It was regretted that, apart from a few words in discussion by Baumgartner (Germany), there was no opportunity to learn of the present status regarding the energy-balance approach

In summarizing one's general reaction to the papers reported above and to the subsequent discussions, one cannot but be impressed by the magnitude of the efforts made to gain a better understanding of the hydrological relationships of the forest At the same time it is evident that much still remains to be done So many aspects have to be considered and so many factors are involved that it is usually not possible to extrapolate findings from one area to another, in this respect the use of regression analysis to define certain underlying relationships has a very promising future It is also clear that most countries do not look at the forest simply as a potential drain on water supplies, to be avoided wherever possible As H C Storey, director of the U S Forest Service Division of Watershed Management Research, pointed out, the emphasis must be on the multiple use of the forest, Lambor (Poland) echoed the same theme in his recommendations for a water economy plan based on the proper appreciation of the comprehensive role of a forest cover

Following the symposium, an excursion was made to various forest catchment experiments in the area Eidmann (Dusseldorf) demonstrated two of his seven stream-gauge installations set up in small catchments to investigate the influence of various types of forest cover and of forest practice, primarily on water yield, at Lahnhof, beech and spruce forest are being compared and at Helgersdorf, coppice and high forest The Ruhrtalsperrenverein, the organization largely responsible for supplying water to the Ruhr industries, has nine similar installations, two of which, on the Runkhauserbach (99 per cent forest) and the Konigswasser (97 per cent arable), were also inspected

Coming from a country with similar water problems, but without a single catchment experiment designed specifically to investigate forest influences, one is greatly impressed by the enthusiasm with which these problems are being tackled in Germany. It is not difficult to criticize many of these installations; precipitation measurements, stream-gauge design, the possibility of leaks and questionable comparability of catchments, all raise problems which could readily intimidate the ultra-cautious particularly in view of the costs involved. Nevertheless, with the example set by the Americans, Germans and other nationals, and with access to their knowledge and experience, can we in Britain afford not to set up similar experiments of our own? L. LEYTON

Lysimeters

A lysimeter is an apparatus used for measuring the quantity or quality of water which has percolated through a container which is filled with soil or similar material. It is easy to see that, within such a definition, lysimeters can be used for such a variety of specific purposes that each installation must be considered on its own merits; an ever-present danger is to interpret what is measured by means of the lysimeter as being representative of any conditions other than those obtaining in the lysimeter itself.

Lysimeters are commonly installed to throw light on what happens in the field, where many different factors affect the amount of percolated water. The position is essentially similar to that encountered in measuring temperature, rainfall and other meteorological factors, where, however, arbitrary standards of measurement have been accepted for purposes of making comparisons between values obtained at different sites. So far, standard conditions have not been accepted for lysimeter installations and readings, and indeed comparatively few suggestions have been put forward for standardization of observations.

It is thus not surprising that several of the papers read at the symposium described lysimeters which could throw some light on what happened, with the passage of time, only in particular circumstances. Various ingenious and, in some cases, expensive installations have been set up, in which care has been taken to avoid such things as disturbance of the natural soil profile, or of the homogeneity of the vegetation cover. But in almost none were there lacking unmeasured variables which, even though in some cases a correlation with adjoining field conditions could satisfactorily be established, allowed of any trustworthy comparison between one site and another.

W. C. Visser, of the Netherlands, was one of those who read papers pointing out that conditions in a lysimeter are essentially artificial, and that the factors introduced by this artificiality need to be measured or eliminated. Visser particularly recommended water-flow potential measurements in the field to 'calibrate' the lysimeter measurements; this involves measuring ground-water depth, tension in the capillary zone, tensions in the plants, and vapour pressures in the air. K. Ubell, of Hungary, placed emphasis on the need to have constant records of the temperature gradients in the field and in the lysimeter. Harrold and Dreibelbis, in describing some of the work at the well-known installations at Coshocton, Ohio, showed themselves vividly aware of difficulties, which have failed to be understood by some who have quoted the Coshocton results too uncritically.

Lysimeters can broadly be divided into those measuring volume and those measuring weight. There is much to be said for the latter, because not only do they help to overcome the problem of changes in the amount of water stored in the lysimeter, but they also enable changes to be recorded as continuously as is desired; lysimeters working on volumes of outflow water necessarily have by contrast a much more considerable time-lag. Several speakers, however, pointed out that weighing lysimeters were not the complete answer which some had incautiously considered them to be; for example, one is not sure whether what is being weighed at one season is strictly comparable to that being weighed at another time of the year.

E. J. Winter (Great Britain) read a joint paper by P. J. Salter, G. Stanhill and himself describing the installations at the National Vegetable Research Station in Warwickshire. Besides directing attention to some interesting and significant results which need further investigation, he stressed that much satisfactory and adequate practical advice can now be given to growers, even though more research is needed to elucidate the mechanisms of, and variations in, the water balance.

G. F. Makkink, in describing the various installations in the Netherlands, made the following useful summary remark: "It is considered the final aim of lysimeter research to gain an insight into the water balance of any natural soil-profile as a function of climate, vegetation and movement of the ground water. This aim widely surpasses the limited scope of the lysimeter observation of the separate institutions who own them". The recognition of this has led to appreciable progress in the Netherlands in co-ordinating results.

Several speakers, particularly G. L. Dupriez (Belgian Congo) and F. H. W. Green (Great Britain), emphasized the value of first obtaining observations of potential evapo-transpiration, under 'standard' conditions, at a network of stations. Cheap oil-drum lysimeters were found to be quite adequate for this purpose, if both sited and handled under comparable conditions. Green pointed out that, by simple subtraction, one could get reasonably reliable values of the seasonal differences in 'water deficit' and 'water surplus' from station to station, even where the absolute values of potential evapo-transpiration and of rainfall were open to doubt. In this connexion, several speakers emphasized the difference between the rainfall measured in rain-gauges at the standard height and that falling on the ground. In both Britain and Germany this seemed to be of the order of rather more than 5 per cent; ground-level gauges are therefore installed at most German lysimeter stations.

One of two week-end excursions at the end of the symposium was devoted primarily to visiting lysimeter installations. The first of these visited was in the Senne heathlands, near Bielefeld, and was operated in connexion with the water undertaking of that town. It consisted of four weighing lysimeters, one metre square cross-section, filled (in three cases) with 'monolith' blocks from three different soil profiles found in the area (the fourth was a 'disturbed' block from one of the areas). None of these lysimeters was irrigated, so that, particularly in a dry year like 1959, the lysimeters could supply facts but not explanations.

The second place visited was to an ingenious forest installation at Bossendorf, near Haltern, in Westphalia. Here, in addition to a more orthodox lysimeter in an adjoining arable field, were two batteries of four lysimeters each, one under a stand of conifers and one under a stand of broad-leaved trees These had been made by pressing large rain-gauge-shaped lysimeters upwards into the soil under the trees, from a horizontal gallery, painstakingly excavated to avoid disturbance of the natural conditions The aim was limited to measuring differences in rates of recharge of soil-water, but they have not been operating long enough for the results to be assessed

The third visit was to the installation of the Dortmund Waterworks at Geisecke on the Ruhr Here there are batteries of (*a*) volume lysimeters, and (*b*) weighing lysimeters, filled with different materials and with different vegetation covers Although undoubtedly useful information is obtained, the results from type (*a*) might be queried in view of the very large amount of bare concrete surrounding the tanks, while in both types (*a*) and (*b*) reasonable homogeneity with the surrounding vegetation was achieved only in certain of the tanks In fact, the series of records from each of these lysimeters, as at some other installations, could be considered only separately, and not safely compared with those from any of the others

F. W GREEN

OBITUARIES

Prof. H. J. Backer

HILMAR JOHANNES BACKER was born at Dordrecht on January 13, 1882, and died at Glimmen, near Groningen, on April 29, 1959 He was a pupil at the Gymnasium in Dordrecht and studied at the University of Leyden under Franchimont in chemistry and H A Lorentz in physics His doctoral thesis was entitled "De Nitraminen en hunne Electro-chemische Reductie" He also worked with Elbs at Giessen on the technique of electrochemical reduction and later in the Davy Faraday Laboratories at the Royal Institution in London After two to three years on the staff at Leyden and a similar period in industry and in Government service, he was called to the chair of organic chemistry at Groningen in 1916 as successor to J F Eykman His colleague, Dr J Strating, said that Backer soon showed his capacity for hard work, for concentration and for utilizing every free moment, and yet it seemed that the passage of years only increased his broad humanity

A survey of his researches (1905–55) reveals an increasing occupation with compounds containing the $-SO_2-$ group This can be correlated with the early work of Franchimont on α-sulphopropionic acid which Backer and Franchimont resolved in 1914 by means of strychnine Backer then prepared and resolved α-chloro- and α-bromo-sulphoacetic acids, α-seleninopropionic acid, α-sulphobutyric acid, several α-arsenocarboxylic acids and also chlorobromoacetic acid

About 1930 he began a study with Strating of the unsaturated cyclic sulphones formed from sulphur dioxide and butadienes The close relation of these compounds to the thiophens led to a study of the oxidation of thiophen homologues in the hope of obtaining the corresponding sulphones Thiophen itself, on oxidation, gives a 'sesquioxide', presumably formed by 1 4-addition between the unstable sulphoxide and sulphone of thiophen It was found that certain dialkyl- and diphenyl-thiophens gave sulphones on oxidation, tetraphenylthiophen had long been known to do so This was attributed to the presence of the substituents which increased the electron availability on the sulphur atom In some cases a sesquioxide was formed On the other hand, electron-attracting groups in the benzene nucleus of 3 · 4-diphenylthiophen inhibited sulphone formation

In 1952 Backer began to study imenes of the type $(R\,SO_2)_2C{=}C{=}NR'$, which are very reactive Three of these have recently been submitted to X-ray analysis by Wheatley, Bullough and Daly in Leeds with very interesting results

At the beginning of the occupation of the Netherlands in 1940, Backer gave much help and advice to his students, whose whole world had suddenly fallen to pieces He kept in touch with all those who were forcibly deported to Germany, sent them parcels and encouraged and advised their parents. When I visited Backer in 1947, he referred only briefly to his imprisonment in 1945 and said nothing of the physical violence which he endured during interrogation The other occupant of his cell was shot The liberation of Groningen probably saved Backer from the same fate

Later on, two of my research students visited Groningen at Backer's invitation, lived in his house for some weeks and worked in his Department Dr A Ash wrote "It was his habit to have students lodging with him and he liked nothing better than for students to call in the evening for a short talk; help or advice were gladly given He interested himself also in their social life He methodically inquired of his students' progress every morning and imparted an impressive practical technique particularly rich in devices for facilitating manipulation of small quantities" Dr A G Lowther has said "One's immediate impression on meeting him was that here was a man who demanded one's respect and affection This was not only a first impression—it was there among his students—they had a real affection, almost love, for Prof Backer He never appeared to be hurried, was most courteous and had a quiet, but real, sense of humour I never heard one word of criticism of him there was a serenity about him and his house"

Dr Strating wrote "Nothing could prevent him from helping a friend or a student who was in need, and this, no doubt, led to his arrest" Backer was a knight of the Order of the Netherlands Lion, a member of the Royal Academy of Sciences in Amsterdam, a correspondent of the Paris Academy of Sciences and an honorary member of the Solvay Institute in Brussels He received honorary doctorates from the Universities of Ghent and Lille

When those who knew him recall Backer's achievements as a man and as a chemist, his great capacity for friendship and for hard work, his fearlessness and his quiet mind, they feel that he went far towards solving happily the eternal problem, *si jeunesse savait, si vieillesse pouvait*

FREDERICK CHALLENGER

Prof. E. S. Salmon

AFTER a long illness, Prof. Ernest Stanley Salmon died on October 12 at the age of eighty-eight.

Anyone unfamiliar with mycology might be pardoned for thinking that his reputation rested on the breeding of new varieties of the hop (*Humulus lupulus* L.). Yet when he came to Wye College (University of London) in 1906, he had already established himself as the authority on an important group of fungi. Researches at the Jodrell Laboratory, Kew, had led to the publication, in 1900, of "A Monograph of the Erysiphaceae", a work which remains fundamental for systematic mycology and which was reproduced as microcards only a few months ago. After further study in the laboratory of Prof. Marshall Ward at Cambridge, he demonstrated the very highly developed specialization of parasitism in the same group; accounts of this may be found in the *Transactions of the Royal Society*, 1904 and 1905.

Salmon was appointed to Wye College to study diseases of plants and so was probably the first professional plant pathologist in Britain. There were then few helpful text-books, but it was not long before he had combined laboratory work and field experiments to good purpose. His first papers, which may even now be read with profit, describe in some detail a selection of the diseases of crop plants; the main emphasis being on apple scab (*Venturia inaequalis* (Cooke) Wint.) and other pathogens of fruit. Bordeaux mixture and lime sulphur, fungicides which are still in use, were introduced to Kentish orchards, while he conducted a vigorous campaign in the Press and elsewhere which led to the passing of the Destructive Insects and Pests Act in 1907.

He was elected president of the British Mycological Society in 1911; appointed reader in economic mycology in the University of London in 1912, professor of mycology in 1925 and emeritus professor in 1939. He was made Fellow of Wye College in 1948.

When, soon after the First World War, the specialist advisory service in Britain began, he was appointed advisory mycologist of the Wye Province. Until he relinquished this appointment in 1937, he led a series of investigations on diverse plant diseases. Particularly noteworthy are the contributions on fruit and hops with which are associated his colleagues, Drs. H. Wormald and W. M. Ware.

Salmon arranged a programme of hop breeding in 1907 and followed this without a break until his last illness. From the beginning, one of his main aims was to produce varieties with exceptionally high preservative values; such varieties would enable the British grower to compete with imported American hops. In order to have at command a wide range of diverse types, he assembled male and female plants from different parts of the world; this unique collection, together with selected progeny, for long occupied about an acre of ground at Wye College. Of the many thousands of seedlings raised, his earliest success was the English-grown American, Brewer's Gold. This was $F1$ from an English male hop and a wild hop from Morden, Manitoba. Paradoxically, the variety has been more widely grown in Canada and the United States than in Britain. The varieties Bullion and Northern Brewer which have become so popular with the British hop industry during the past decade are $F1$ and $F3$ seedlings, respectively, of parents from the same sources. Other seedlings of his raising proved to be tolerant to hop wilt (*Verticillium albo-atrum* Reinke and Berth.) and these have been of great value for planting in infected soil.

In recognition of his work on hops he received in 1955 the Horace Brown Medal, the highest honour which the Institute of Brewing can bestow.

After the manner of the pioneer, Salmon was a strong individualist and, in his later years at least, showed little enthusiasm for gatherings, whether scientific or social. He found relaxation in literature and in his small garden of rare plants.

H. H. GLASSCOCK

Prof. J. Zenneck

PROF. JONATHAN ZENNECK, one of the earliest pioneers of radio science, died in Munich in April, a few days before his eighty-eighth birthday. Prof. Zenneck was born in 1871 in Württemberg, Germany, and studied mathematics and natural science at Tübingen, where he obtained his doctorate in 1894. In the following year he became an assistant in the Physical Institute in Strasburg; he moved to Dantzig in 1905 to become assistant professor, and later (1911) professor of physics in the Institute of Technology. His academic career was continued by his appointment in 1913 to the chair of physics at the Technical High School of Munich, where he remained until his retirement.

Most of the basic contributions of Prof. Zenneck were made in the days when spark transmitters were used for wireless telegraphy, concurrently with the development of high-frequency machines and arc generators to produce undamped oscillations for radio-telephony. Among the earliest of his achievements was the establishment of the first radio-link for navigational purposes between Cuxhaven and Heligoland in 1899–1900. His basic experimental and theoretical contributions to wave propagation were of great importance in the early development of wireless communications. He expounded the first theory on wave propagation along the Earth (Zenneck wave) which explained the effect of the ground constants on polarization and absorption of the waves. Also well known are his basic contributions to ionospheric research, which he initiated in Germany; and he was the founder of the first German ionospheric research station, Herzogstand, in Kochel, Bavaria, which was in operation until 1945.

Dr. Zenneck's interests were not limited to radio. He also contributed to other areas in the general field of applied physics such as acoustics and gas discharges. He was the author of the first German text-book on wireless telegraphy, "Electromagnetic Oscillations and Wireless Telegraphy", published in 1906, which was the classic work in this field for many years. He was also the editor of the *Hochfrequenztechnik und Elektroakustik*, the leading journal of the world during the early days of radio.

His second book, entitled "Wireless Telegraphy", was published in Germany in 1908, and a second edition appeared four years later. It was translated into English in 1915 by A. E. Seelig, and published in London and New York, forming one of the most useful text-books available to students at that time on the generation, propagation and detection of electromagnetic waves in the radio part of the spectrum.

He received many honours and medals from academic and professional societies, including an honorary doctor's degree from the Institute of Technology at Dresden He was made a fellow of the Institute of Radio Engineers (N Y) in 1915, received its medal of honour in 1928, and was a member of the board of directors and vice-president in 1933 He was honorary president of the German National Committee of the International Scientific Radio Union, and was elected vice-president of that Committee in 1938 All those who had the pleasure of meeting Prof Zenneck at international conferences will remember his charming personality and his modest simplicity, combined with wittiness and quickness of repartee.

R L SMITH-ROSE

NEWS and VIEWS

Nobel Prize for Physics for 1959 :

Dr Emilio Segre and Dr Owen Chamberlain

Dr Segre and Dr Chamberlain, who have been awarded the Nobel Prize for Physics for 1959, have collaborated in research in high-energy physics for a number of years at the Lawrence Radiation Laboratory of the University of California at Berkeley Dr Segre was born in Italy in 1905 and was a member of Fermi's remarkable nuclear research school in Rome He emigrated to the United States before the War Dr Chamberlain is thirty-nine and, like Dr Segre, is a distinguished experimentalist Their collaboration at Berkeley has been associated with the great accelerators which have been built there over the years They were the leading members of a team engaged in experiments on nucleon-nuclear interaction with the help of the 184-in synchrocyclotron, and in particular made a detailed study of polarization phenomena in high-energy scattering The work which has now been honoured by the Nobel award has, however, been their discovery in 1955 of the antiproton in experiments with the 6 GeV -proton synchrotron, the bevatron The existence of the antiproton had been confidently postulated for many years , the discovery of the positron in 1932, and its interpretation on the Dirac theory, also implied the existence of other anti-particles including a negatively charged proton Antiprotons stubbornly eluded discovery in the very high-energy (but very low-intensity) bombardments of cosmic radiation, and one reason for building the bevatron was to have an intense beam of sufficiently energetic protons to create proton–antiproton pairs in the laboratory

The actual discovery, however, involved a long series of painstaking experiments with very elaborate detection equipment which had to be specially developed The development of effective techniques for beam separation and detection for use with machines of very great energy is a field of research in itself The antiprotons produced when a beam of high-energy protons falls upon a target in a machine like the bevatron are very greatly outnumbered by other charged particles produced with very broad momentum spectra in the relativistic region These background particles would cause impossible confusion in the detection apparatus if they were not systematically eliminated Their elimination in the experiments of Segre and Chamberlain was a major programme in experimental physics The final apparatus used was elaborate and refined Charge and momentum separation of antiprotons from the mixed beam of particles was achieved by magnetic deflexion and focusing in separate lenses, and velocity selection was aided by time-of-flight and Čerenkov radiation techniques When some forty events had been accumulated which corresponded within acceptable margins of error with the properties of the antiproton, it could be said that the antiproton had been discovered As is usual in high-energy research with large machines, team-work by large numbers of physicists and engineers was involved , the award of the Nobel prize to Segre and Chamberlain underlines the fact that the brilliant individual worker is still needed to inspire and direct the work

Royal Society Medals for 1959

THE following awards of medals have been made by the President and the Council of the Royal Society *Copley Medal* to Sir Macfarlane Burnet, director of the Walter and Eliza Hall Institute, Melbourne, Australia, for his distinguished contributions to knowledge of viruses and of immunology *Davy Medal* to Prof R B Woodward, of the Department of Chemistry, Harvard University, Cambridge, Massachusetts, for his distinguished researches in organic chemistry and particularly for his contributions to the structure and synthesis of natural products *Hughes Medal* to Dr A B Pippard, reader in physics in the University of Cambridge, for his distinguished contributions in the field of low-temperature physics

Genetics at Cambridge : Prof J M Thoday

A GRADUATE of the University College of North Wales, Bangor, Dr J M Thoday, who has recently been appointed to the Arthur Balfour chair of genetics in Cambridge, began his research career in the Botany School, Cambridge, under the guidance of Dr (now Prof) D G Catcheside These early studies of the action of ionizing radiations on chromosome structure were interrupted by war service in the Royal Air Force, to be resumed after the War at the Mount Vernon Hospital and Radium Institute, where, in collaboration with Dr J Read, Thoday demonstrated the effect of oxygen tension on the frequencies of chromosome changes following irradiation During 1947 he moved to Sheffield to take up an appointment as lecturer in cytogenetics, becoming senior lecturer in charge of the newly founded Department of Genetics there in 1954 In Sheffield his research moved towards the field of population genetics, particularly in relation to the genetical control of stability in development and to the action of disruptive selection His experiments with *Drosophila* have been especially rewarding in the light they have thrown on the power of disruptive selection to conserve variability and to build up polymorphisms within populations They are showing us for the first time under controlled conditions how polymorphisms can come into being and how their genetical structure reflects the selection which has brought them about Prof Thoday's breadth of experience and originality of approach augur well for the future of genetics in Cambridge

Genetics at Sheffield : Dr J A Roper

DR J A ROPER returns to his own University (Sheffield) as the first holder of the new chair of genetics. Dr. Roper graduated in chemistry at Sheffield in 1945, and was trained in bacterial biochemistry under Krebs and McIlwain. He joined the Genetics Department at Glasgow in 1948 and played a very important part in the development of that school of genetics. For his ability as a teacher, and his engaging personality, he is well liked by the students. At Glasgow he introduced, with great success, group discussion methods. Dr. Roper was Rockefeller Fellow in 1953 at the California Institute of Technology, and has lectured at various times in a number of American and European universities. He is secretary of the Genetical Society.

Dr. Roper's training in chemistry and microbial biochemistry was a good foundation for the research in microbial genetics on which he embarked at Glasgow. He played a major part there in a team working on the genetics of *Aspergillus nidulans*. A most decisive contribution was the first deliberate search for, and his demonstration of, what could be called the 'splitting of the gene' (*Nature*, 166, 956; 1950). Soon after he designed a way of synthesizing heterozygous diploid strains in filamentous fungi. This was the first step which made possible the discovery of the 'parasexual' cycle and the development of genetic analysis *via* mitotic segregation. In the past three years Dr. Roper has become interested in investigating extra-nuclear inheritance in *Aspergillus*. Dr. Roper's ability in teaching and research will be given full opportunities in this new chair, born in a most favourable environment.

The Animal Health Trust

H.M. the Queen has graciously consented to become patron of the Animal Health Trust. The Trust was founded by Dr. W. R. Wooldridge in 1942 for the purpose of improving the general health standards of all types of domesticated animals, and it approaches the task in two ways: First, by means of scientific investigation of the many disease problems of such animals; secondly, by stimulating the flow of trained personnel into the ranks of the veterinary profession through financial grants to needy students and by furthering the higher education and specialization of veterinary graduates. Four research centres have been established by the Trust for the study of disease in horses, dogs, poultry and farm animals, respectively, the latest of which—the Farm Livestock Research Centre at Stock, Essex—was opened by H.R.H. Prince Philip in December 1957 (see *Nature*, 181, 76; 1958). A new surgical unit to mark the patronage of the Queen is to be built at the Equine Research Station, Newmarket, at a cost of about £30,000.

The Office of the Lord Privy Seal

With the appointment of Lord Hailsham as the Minister with general responsibility for science and technology, including atomic energy, the Atomic Energy Office and the Lord President's Office will be combined. The new Office will be in the charge of Mr. F. F. Turnbull, whose appointment as deputy secretary, to succeed Sir Friston How in charge of the Atomic Energy Office, was announced some months ago. It will be organized in two Divisions: (1) a General Division, under Mr. R. N. Quirk, under-secretary, corresponding to the previous Lord President's Office; and (2) an Atomic Energy Division, under Mr. M. I. Michaels, under-secretary, corresponding to the previous Atomic Energy Office.

Parliamentary Responsibility for Science and Technology

The Prime Minister made a statement in the House of Commons on October 30 regarding the responsibilities of the Lord Privy Seal and the Minister for Science, stating that other Ministers would remain responsible for the scientific establishments within their own Departments, but that the Minister for Science was to be responsible for broad questions of scientific policy outside the sphere of defence, and was advised by the Advisory Council on Scientific Policy on general questions which relate to the whole field of civil science. On November 3, Mr. Macmillan indicated that the arrangements for answering questions in the House of Commons which fall within the responsibility of the Minister for Science would be as follows: questions about the Medical Research Council and radiobiological hazards, the Minister of Health; Agricultural Research Council and Nature Conservancy, the Minister of Agriculture; nuclear energy, the Department of Scientific and Industrial Research and general scientific matters, the Minister of Education; space research, the Minister of Aviation. Where questions about the development of nuclear energy relate to matters for which some other Minister is responsible, that Minister would answer them. For example, questions about nuclear-powered merchant shipping would normally be answered by the Minister of Transport, and about nuclear power stations by the Minister of Power. Mr. Macmillan had earlier defended the exclusion of the new Minister of Power from the Cabinet, but neither that arrangement nor those for answering questions for the Minister of Science in the House of Commons were well received.

Scientific Developments in Britain

Replying to a question in the House of Commons on November 2, Mr. J. B. Godber, as representing the Lord Privy Seal, said that a small temporary station is to be established near Cambridge to expand the work already being done at the Low Temperature Research Station and elsewhere, and he hoped it would be in operation by the end of next year. Meanwhile, the Agricultural Research Council is considering the wider issues raised by the proposal to establish a permanent centre for meat research. In a written answer on November 5, the Minister of Education, Sir David Eccles, as representing the Minister for Science, stated that the new Hydrodynamics Laboratory of the National Physical Laboratory had cost about £2 million, and its staff was nearly 70, including 10 scientific officers. The Laboratory would provide up-to-date facilities for testing ship designs, particularly in reproducing more realistic sea conditions, and research would be conducted to extend basic knowledge of the resistance, propulsion and sea-going qualities of ships, while new ship designs would be tested for industry.

In a written reply to a further question on November 5, Sir David Eccles said that commissioning trials of the fast reactor at Dounreay had proved more difficult than expected, due to chemical engineering problems, but enriched uranium is now being loaded and the reactor is expected to become critical within the next few weeks. This reactor, he said, is an experiment in the development of fast breeder systems, and successful exploitation will depend upon the operating results: the development of the fast reactor will occupy the resources of the Dounreay establishment for many years. The Admiralty submarine reactor development programme at Dounreay is now getting under way, and firms in the north of Scotland with the necessary scientific and technical experience would be given the opportunity of tendering for any development work which could be let out to industry.

Inauguration of *Merlin*

WHEN H.R.H. the Duke of Edinburgh formally inaugurated *Merlin*, the nuclear research reactor built by Associated Electrical Industries Ltd. (see *Nature*, September 5, p. 11) at Aldermaston on November 6, an underwater closed-circuit television camera specially designed by E.M.I. Electronics Ltd. made possible the observation of activity inside the reactor. This camera, which is 30 in. long, 3½ in. in diameter, and enclosed in a pure aluminium water-tight housing, is a permanent part of the equipment of *Merlin*. In addition, a standard E.M.I. camera has been mounted above the reactor, on the second floor of the reactor hall. This provides a continuous view all around *Merlin*, and ensures that no unauthorized staff are near the reactor when it is in use. Two 14-in. receivers, one for each camera, have been rack-mounted in the control room on the ground floor and another receiver has been installed on the second floor for observation inside the reactor. A 17-in. console receiver, capable of selecting a picture from either camera, has been installed in the reactor conference room. Three more E.M.I. cameras and seven more receivers were used at the opening ceremony to give the audience an uninterrupted view of the proceedings from the moment the Duke of Edinburgh entered the reactor hall on the ground floor, while he was inspecting the top of *Merlin* from the second floor, and upon his return to the ground floor to start the reactor and unveil a commemorative plaque.

Joint British Committee for Vacuum Science and Technology

FOLLOWING the Institute of Physics' London Conference on high vacua held in April last, various suggestions were made for arranging regular meetings in Britain on vacuum science and technology, and for British participation in international conferences in this field. As a result of informal discussions, a Joint British Committee for Vacuum Science and Technology has now been formed. The Committee consists of representatives from each of the following bodies: Institute of Biology, Institution of Chemical Engineers, Royal Institute of Chemistry, Institution of Electrical Engineers, Iron and Steel Institute, Institution of Mechanical Engineers, Institute of Metals, Institute of Petroleum, Physical Society and Institute of Physics. Its objects are (*a*) to co-ordinate and help to initiate meetings in the whole field of vacuum science and technology arranged by constituent bodies; and (*b*) to act in the collective interest of the constituent bodies by maintaining liaison with the International Organization for Vacuum Science and Technology and with national vacuum societies, and otherwise. The Institute of Physics has agreed to provide the secretariat for the joint committee; communications should be addressed to the Secretary of the Joint British Committee at 47 Belgrave Square, London, S.W.1.

Scientific Policy in South Africa

THE first and second annual reports of the Advisory Council on Scientific Policy of the Union of South Africa cover the periods December 1956–December 31, 1957 (pp. 5) and January 1–December 31, 1958 (pp. 7), respectively (Pretoria: Advisory Council on Scientific Policy, 1958 and 1959). The Council, which has nine members, including Prof. H. O. Monnig as chairman, was appointed late in 1956 to enquire into and report on all matters referred to the Council by the Minister of Economic Affairs. It is required to acquaint itself with scientific developments and policy in other countries and to advise the Minister concerning any action necessary in South Africa; to take note of all international scientific conferences and make recommendations regarding representatives; and to investigate cases of overlapping of research and other activities referred to the Council by the Minister and make recommendations as to responsibility for the work.

In its first report the Advisory Council, attributing the shortage of scientists and technologists fundamentally to weaknesses in secondary education, recommended that the Government should increase both funds and facilities available for training scientists at the universities, as well as actively promote the training of technologists and improve the salaries and conditions of employment of scientists. A survey of the country's requirements for scientists and technologists by the Research Bureau of the Department of Education, Arts and Science was also recommended, and the Council's consideration of the condition and organization of research issued in a recommendation for the appointment by the Government of a commission to investigate the organization of agricultural research and the establishment of an independent Agricultural Research Council. The Advisory Council does not consider its responsibility regarding attendance at international conferences can be satisfactorily discharged under the present arrangements or that the set-up permits adequate access in general to Cabinet level.

In its second report the Advisory Council recommends the compilation and maintenance by the National Bureau for Educational Research of a National Register of Scientists and Technologists. Some consideration was given to the relation between the Council for Scientific and Industrial Research and the universities, and at the request of the South African Chemical Manufacturers' Union the Council considered the desirability of Government support for research on the processing of agricultural products, but concluded that the proposal was undesirable and that developments in this field should be left with the Council for Scientific and Industrial Research. An inquiry into overlapping of State-aided research, requested by the Treasury, led to the recommendation that the Government Metallurgical Laboratory should become an institute of the Council for Scientific and Industrial Research. A Cabinet Committee has been appointed to investigate the shortage of man-power in science and means of reducing this shortage, and a commission is investigating the desirability of an independent Agricultural Research Council, but otherwise no action appears to have been taken on the recommendations suggested in the first report.

Inland Telegraph Service

THE Committee appointed during December 1957, under the chairmanship of Sir Leonard Sinclair, "to advise the Postmaster-General on the future place of the inland public telegraph service as part of the communication facilities of the United Kingdom", does not consider that, subject to keeping under review the extended use of the telephone for sending telegrams over the shorter distances, further integration of telegraphs with telephones, as recommended by the Bridgeman Committee of 1932, would be justified at present, though there may be scope for further integration with the telephone service or possibly with the telex service later The number of telegrams has steadily declined from 53 3 millions in 1947–48 to 18 7 millions in 1956–57 and an estimated 16 9 millions in 1957–58, and the loss per telegram has risen from 14 2*d* to 40 3*d* in 1956–57 and 48 2*d* in 1957–58 This is mainly due to the relatively small gap in the communications facilities of the United Kingdom filled by the service and this gap is being reduced in size by other Post Office services Foreign administrators face a similar problem and the traffic is expected to continue to decline Although the service is only of marginal importance to business establishments and only occasionally used by the public for social purposes, in its report the Committee recommends retention of the service to handle a proportion of overseas and emergency telegrams and for other reasons (Report of the Advisory Committee on the Inland Telegraph Service, 1958 Pp iii+11 London H M Stationery Office, 1958 1*s* net) Increase of the tariff is recommended and the new structure should be one of a basic charge plus a charge for every word The Post Office, it is suggested, should consider the elimination or reduction of the deficits due to Press traffic and telegrams to the Irish Republic and should arrange to charge the British Transport Commission with the cost of Railway Pass telegrams

Meldola Award

It is announced that the next award of the Meldola Medal will be made early in 1960 to the chemist who, being a British subject and under thirty years of age at December 31, 1959, shows the most promise as indicated by his or her published chemical work brought to the notice of the Council of the Royal Institute of Chemistry before December 31 The merits of the work may be brought to the notice of the Council, either by persons who desire to recommend the candidate or by the candidate himself, by letter addressed to the President, Royal Institute of Chemistry, 30 Russell Square, London, W C 1, from whom further information can be obtained

Royal Society of Edinburgh . Officers for 1959-60

At the annual statutory meeting of the Royal Society of Edinburgh the following officers and members of Council were elected *President* Prof E L Hirst, Department of Chemistry, University of Edinburgh *Vice-Presidents* Dr D P Cuthbertson, Mr A W Young, Prof T Neville George, Prof J R Matthews, Dr T R Bolam, Dr Douglas Guthrie *General Secretary* Prof Norman Feather, Department of Natural Philosophy, University of Edinburgh *Secretaries to Ordinary Meetings* Dr A W Greenwood and Dr Mowbray Ritchie *Treasurer* Dr J R Peddie *Curator* Dr R Schlapp *Councillors* Prof A M MacBeath, Prof R A Rankin, Prof A E Ritchie, Prof V C Wynne-Edwards, Prof E G Cullwick, Prof G Pontecorvo, Prof M M Swann, Prof H A Bruck, Prof T S Westoll, Dr H R Fletcher, Prof G L Montgomery, Prof W L Weipers

Announcements

The Minister for Transport and Power for the Republic of Ireland has appointed Mr J Connor, of the Department of Transport and Power, to be chairman of the National Committee for Geodesy and Geophysics in succession to Mr A Ó Coinneain

Mr R Levin has been appointed development planning executive at Aspro-Nicholas, Ltd , of Slough, Bucks Mr Levin was formerly chief pharmacist, Research and Development Division, and lately manager of the Technical Information Department of the Distillers Co (Biochemicals), Ltd He is the author of "The Pharmacy of Silicones and their Uses in Medicine"

Following the resignation of Dr C. E Dalgliesh as secretary of the Biochemical Society, Dr P N Campbell, Courtauld Institute of Biochemistry, Middlesex Hospital, London, becomes secretary to the Committee, and Dr W J Whelan, Lister Institute, Chelsea Bridge Road, London, S W 1, has been appointed meetings secretary

The National Collection of Industrial Bacteria has been transferred from the National Chemical Laboratory to the Torry Research Station (Department of Scientific and Industrial Research) All future inquiries and correspondence concerning the Collection should be addressed to the Curator, National Collection of Industrial Bacteria, Torry Research Station, Aberdeen

A symposium on hæmatology has been organized by the University of Cambridge Post-Graduate Medical School, and will be held during December 7–9 Further information can be obtained from the Secretary, Medical School, Tennis Court Road, Cambridge

The U S Office of Naval Research has announced that the second Conference on Semiconductor Surfaces will be held at the U S Naval Ordnance Laboratory, White Oak, during December 3–4 Further information can be obtained from the chairman of the Steering Committee, Dr J N Zemel, U S Naval Ordnance Laboratory, White Oak, Silver Spring, Md

The Indian Society of Theoretical and Applied Mechanics has announced the Fifth Congress on Theoretical and Applied Mechanics, to be held at the University of Roorkee during December 23–26 Further information can be obtained from the Secretary-Treasurer, Indian Society of Theoretical and Applied Mechanics, Institute of Technology, Kharagpur, India

The autumn general meeting of the British Iron and Steel Institute will be held in London during December 2–3 The sessions, some of which will run simultaneously, will be held in the Great Hall, Caxton Hall, S W 1, and in the Hoare Memorial Hall, Church House, S W 1 Further information can be obtained from Mr K Headlam-Morley, Iron and Steel Institute, 4 Grosvenor Gardens, London, S W 1 All applications must be returned by November 27

Erratum In the article entitled "Transmission of a Virus to Strawberry Plants by a Nematode (*Xiphinema* sp)" in *Nature* of September 26, p 962, line 5 in par 2 should not have been inserted The phrase should read " the causal virus of yellow crinkle and of mosaic was transmitted by mechanical inoculation from plants of a number of strawberry varieties, including "

INTERNATIONAL UNION OF PURE AND APPLIED CHEMISTRY

COMMISSION ON GEOCHEMISTRY

THE Commission on Geochemistry of the International Union of Pure and Applied Chemistry held a meeting in Munich during August 26–27, during the twentieth Conference of the Union Attending the meeting were the following members of the Commission Prof T F W Barth (*president*), Dr F M Vokes (*acting secretary*), Prof C Burri, Prof C W Correns, Prof S I Tomkeieff, Prof L R Wager, Prof F E Wickman and three observers of the Commission Prof A P Vinogradov, Prof K Sugawara and Prof E Ingerson

The Commission discussed at length its future objects and aims, particularly with regard to the work of its sub-committees The chairmen of the three existing sub-committees reported on their activities, these comprise the subcommittee on abstracting, translation and information, the sub-committee on the chemistry of the oceans and the sub-committee on rock analyses It was decided to broaden the scope and work of the Commission by forming sub-committees on "the organic compounds in the crust of the Earth" and "the beginning of the biosphere"

It was also considered highly desirable that some form of code should be compiled which could be used to indicate the exact analytical methods which had been employed in mineral and rock analyses reported in publications It was decided to seek the co-operation of the Sections of Inorganic and Analytical Chemistry of the Union to further this end The question of education and training for geochemistry was also discussed at some length In particular, it was agreed that the education committee of the Geochemistry Society should be encouraged to produce a definitive report on this subject as a basis for further discussion

The subject of future symposia on geochemistry came in for a considerable amount of discussion It was decided to offer the Commission's co-operation in respect of the proposed symposium of the International Union of Geodesy and Geophysics to be held in Helsinki in July 1960, and that of the Geochemical Society to be held in Copenhagen in August 1960 For the Copenhagen symposium it was suggested that the Commission should be responsible for organizing a section of the geochemistry of sedimentary carbonate rocks

Prof A P Vinogradov of the Vernadsky Institute of Moscow gave the members present a short summary of the current geochemical work being carried out at the Institute He also mentioned that discussions were taking place regarding the formation of a Russian geochemical society which he hoped would in time be able fully to co-operate with similar bodies outside Russia Prof K Sugawara also gave a short account of the position and activities of the Japanese Geochemical Society

Election of Members In order to replace those members due to retire at the end of the present year, the following were elected members of the Commission Prof L H Ahrens, Prof E Ingerson, Prof K Sugawara and Prof A P Vinogradov The officers elected for the session beginning 1960 were *President*, Prof C W Correns (Gottingen), *Vice-President*, Prof A P Vinogradov (Moscow), and *Secretary*, Prof E Ingerson (Austin, Texas) In addition, it was decided to invite seven new observers to serve with the Commission The president-elect, Prof Correns, proposed a vote of thanks to the retiring president, Prof Barth, for his work for the Commission during his term of office and this was carried with acclamation

SCIENCE AND PHILOSOPHY

THE fourth annual conference of the British Society for the Philosophy of Science was held during September 25–27 at Newnham College, Cambridge, and was attended by about eighty members and guests Dr M B Hesse was conference secretary

Four symposia were held "Scientific Research and the Philosophy of Science", "Biology and Physics", "Classification, Concept-formation and Language", and "Knowing and Being"

At the first session, with Dr J O Wisdom in the chair, it was argued whether 'philosophy of science' can be held to refer to any activity not properly subsumed under 'scientific research', and, if it can, whether that activity is relevant to research Prof H Dingle mentioned various questions of value and purpose, as well as of method, papers on which were unlikely to be accepted for publication in journals concerned with particular sciences Prof H C Longuet-Higgins, on the other hand, argued that, of the product of philosophers of science, part was science, part was philosophy, and the remainder was of no use to man or scientist This aroused some consternation, as members consulted their own credentials and invoked those of others, but in due course a consensus emerged that scientists have to think critically about their thinking, and the comparative study of modes of scientific thought may help them to do so

In the second session, Prof J H Woodger described an abstractive hierarchy of terms characterized by a one–many relation, and its use as a conceptual framework in biology With some hierarchies of cells, every cell is a distinct life, with others, only the first cell in each hierarchy, elaboration occurring on subsequent levels Morphology was the study of the arrangement and differentiation of parts, physiology was the study of the existential dependence of parts Genetics was concerned with the process in which the first member of a hierarchy results from the conjunction of two members of other hierarchies Dr E M Hutten set alongside this framework the sequence exhibited by radioactive decay each new atom produced was similarly time-extended, stemmed from a parent atom, and consisted of existentially dependent parts, but it was not dependent on its environment analogously to a cell In elementary-particle theory, explanation might amount to little more than classification, or an enumeration of possibilities, and might have little more predictive power than comparable biological models with their over-determination and multiple-causation The chairman, Prof C F A Pantin, referred to the occurrence, in biology, of morphological models that can be interpreted at more than one level in an organizational hierarchy In discussion it was suggested that the predictive power of a theory might not always be manifest at the time of its original formulation, it might have to await development of deduction There was much interest in the relative importance of the past history of an entity in biology and in physics historical existential dependence appears to be a function of complexity

In the third session, with Mr G Buchdahl in the chair, Miss M Masterman and Mr R M Needham presented the strategy, and some of the tactics, of a method of analysing language by assimilating it to a library classification system in which concepts are arranged on a finite lattice ordered by a single, weak, 'concordance' (inclusion) relation They further suggested that the formation of scientific concepts is a development of language according to this model There was some discussion as to whether the method is a technology for mechanical translation, or a science, or a philosophy of language, and it was suggested that it could be viewed as a scientific model of language, containing the partly uninterpreted concept 'inclusion', and capable of being tested by experiments on translation and on analogy-finding

In the fourth session, under the chairmanship of of Dr W H Thorpe, Prof M Polanyi presented a way of talking about the primary process of knowing by perception, the pre-articulate act of knowing, which partakes of the uniqueness of the individual percipient, the unspecifiable personal knowledge from which any specifiable, potentially public, knowledge is derived by a process of abstraction Complex entities were commonly perceived and recognized as wholes before particulars had been identified; the process of discovery, in fact, might be regarded as an alternation of analysis, recognizing particulars, and integration, recognizing the relations of parts to the whole Prof R B Braithwaite suggested that too narrow a view might be taken of specifiability, and that some levels of subjective experience, however vague, could be conveyed by language—for example, 'Oblomov' conveys the experience of laziness, beyond that, he differed from Prof Polanyi in his use of the term 'knowledge' for what was unspecifiable In the subsequent discussion there was some reluctance to focus on this rather undemocratic mode of tacit awareness, and a preference for talking about what can be made public, with the implication that the progressive refinement of scientific language tends to eliminate the unspecifiable

In conclusion, it is perhaps worth directing attention to the unusualness of a scientific conference at which speakers are not armed with specified and verifiable data but attend primarily to make as explicit as possible how they think, and to receive criticism of the process thereby revealed, especially from those who are not working in the same field The coherence of this universe of discourse was illustrated by the frequency of reference from one discussion to another, the *esprit d'escalier* from one session often finding its outlet in a later one, its range, by the frequency of spontaneous quotation, not only from Shakespeare and Wordsworth but also from Swinburne (and early Swinburne, at that). G E Denyer

FOURTEENTH ANNUAL CALORIMETRY CONFERENCE

THE fourteenth annual Calorimetry Conference, held at Yale University in the Sterling Chemistry Laboratory during September 10–12, was attended by more than one hundred scientists from the United States, Canada and Europe Under the chairmanship of Dr David White (Ohio State University) thirty papers were read and discussed These included heat capacity measurements at temperatures as low as 0 1° K and as high as 1,400° K, precision reaction and bomb calorimetry, solution calorimetry, and determinations of stored energy in solids

Most of the papers were concerned with recent developments in calorimetry However, as calorimetric techniques are extended to more extreme conditions, the problems that led to the founding of the Conference remain under new guises The need for better temperature measuring devices was emphasized in seven papers that reported on research at temperatures below 11° K No device comparable to the platinum resistance thermometer, now in general use for measurements above 11° K, is yet available for the very low temperatures at which some of the most important calorimetric research is now being done However, the reports on a device that may extend precision thermometry to at least 1° K, namely, the germanium resistance thermometer developed in the Bell Telephone Laboratories, were received enthusiastically Twelve of these thermometers had been provided for a calorimetry conference test programme involving eleven different laboratories Three papers at the Yale conference described the first results of the investigations, which were so promising that the Conference plans to seek a manufacturer of additional units for a more extensive testing programme

Special addresses were given by Profs George S. Parks (Stanford University) and Lars Onsager (Yale University) At the annual banquet, Parks delivered the Hugh M Huffman Memorial Lecture, "Some Remarks on the Thermodynamic Properties of Organic Compounds" Parks and one of his first graduate students, the late Dr Huffman, started the first systematic calorimetric studies of organic compounds at Stanford more than thirty years ago Enlivening his remarks with many personal anecdotes, Parks traced the history of thermodynamic research on organic substances and the role improvement of calorimetric methods has taken in the remarkable progress made in the past three decades Prof Onsager gave the principal lecture of the technical sessions on "Co-operative Phenomena", a field in which he has developed much of the basic theory Many papers at each Calorimetry Conference describe experimental studies of co-operative phenomena, and Onsager outlined the approaches one may take in seeking a theoretical understanding of such effects Admitting that three-dimensional treatments of critical phenomena by statistical mechanics seem hopelessly complex, he dwelt mostly on more simplified treatments that give results

In addition to the objective of promoting better calorimetric research, the Conference also is concerned with publication policies relating to calorimetric and thermodynamic articles A "Resolution regarding Published Calorimetric Data" adopted by the eighth Conference in 1953 has proved to be valuable to editors and authors alike in establishing consistent policies based on the opinions of experts in the field Because calorimetric research has expanded into many areas not covered by the 1953 resolution, the fourteenth Conference established a committee headed by J P McCullough to consider revising and extending the earlier recommendations Drs Edgar F Westrum Jun (University of Michigan), and Stig Sunner (University of Lund, Sweden) presented a proposal of the Commission on Thermodynamics of the International Union of Pure and Applied Chemistry for a joint meeting in 1961 of the Calorimetry Conference and the Subcommissions on Experimental Thermochemistry and Experimental Thermodynamics The Conference unanimously approved the proposal for a joint meeting to be held either before or after the biennial meeting of the Union that year in Montreal, Canada Plans will begin immediately for what should be one of the most important conferences ever held in the field of calorimetry

At the annual election the following members were appointed to Conference offices *Chairman*, Dr J P McCullough (Petroleum Thermodynamics Laboratory, Bureau of Mines), *Chairman-Elect*, Dr D W Osborne (Argonne National Laboratory), *Directors*, 1959–62, Dr N E Phillips (University of California, Berkeley) and Dr J M Sturtevant (Yale University) Other officers include *Secretary-Treasurer*, Dr C E Messer (Tufts University) and *Directors*, Dr David White, Dr D H Andrews (Johns Hopkins University), Dr J E Kunzler (Bell Telephone Laboratories), and Dr. J A Morrison (National Research Council, Ottawa)

SECOND AUSTRALIAN SPECTROSCOPY CONFERENCE

THE second Australian Spectroscopy Conference, convened by Dr A L G Rees (Division of Chemical Physics, Commonwealth Scientific and Industrial Research Organization) and held in the Chemistry Department of the University of Melbourne during June 1–3, was opened by Prof J S Anderson, who welcomed the 110 participants and the four exhibitors of commercial spectroscopic equipment The first session of the conference was devoted to ultra-violet spectra and began with a review by Prof N S Bayliss (Chemistry Department, University of Western Australia) of recent theoretical work on solvent effects He directed attention to the calculations of Polansky on the interaction between two H atoms which predict a red shift in the atomic spectrum beyond a critical distance and a blue shift at closer distances, to the calculations by Longuet-Higgins and Pople of the red shift in the spectra of non-polar solutes in non-polar solvents arising from dispersive forces, and to McRae's formulations of the case of polar solute and polar solvent The McRae formula predicts a frequency shift between absorption and fluorescence arising from the change of dipole moment between the ground and excited states, thus providing a method for measuring the dipole moments of excited states for comparison with calculated values

One set of contributed papers in this section dealt with the spectra of aromatic hydrocarbons Drs G R Hunt and I G Ross (Physical Chemistry Department, University of Sydney) discussed a vibrational analysis of the 7000 A and 3500 A absorption systems of azulene which appears to confirm the predictions of Pariser and of Moffitt concerning the nature of the excited states Dr L E Lyons and Mr G C Morris (Physical Chemistry Department, University of Sydney) presented results on the absorption of anthracene vapour (38,000 to 60,000 cm^{-1}) They confirmed the second π–π transition as allowed and also observed four members of a Rydberg series converging to an ionization potential of 6 81 eV Dr N S Ham (Division of Chemical Physics, Commonwealth Scientific and Industrial Research Organization) reported some calculations by the free-electron model, with electronic interaction, of the spectrum of the perinaphthenylium cation $C_{13}H_9{}^+$, which agree well with the reported spectrum and also predict an unreported absorption band at about 600μ

Studies by Dr I G Ross and E J Wells (Physical Chemistry Department, University of Sydney) on the interesting tetrahedral molecules OsO_4 and RuO_4 failed to reproduce the extensive fine structure reported in the room temperature spectra by Langseth and Qviller in 1934 The authors gave a vibrational analysis of their spectra and used the energy-level scheme of Ballhausen and Liehr to assign the two allowed transitions A theoretical paper by Dr E G McRae (Division of Chemical Physics, Commonwealth Scientific and Industrial Research Organization) was concerned with electronically excited states of aggregated identical molecules, the intra-molecular vibrations were explicitly included Two limiting cases were recognized, depending on whether the interaction energy was large or small with respect to the vibrational energy An interpretation of the *J* band of N,N′-diethyl-pseudo-cyanine was offered on the basis of this theory

Dr H A. McKenzie (Division of Food Preservation and Transport, Commonwealth Scientific and Industrial Research Organization) spoke on the difference spectra in acid solutions and in urea solutions of bovine serum albumin, ovalbumin and conalbumin

Dr L E Lyons (Physical Chemistry Department, University of Sydney), in opening the session on solid state spectroscopy, described a number of the effects observed in ionic solids and semi-conductors Such effects include structure in the absorption edge of the conduction band, hydrogen-like absorption series due to excitons, the high intensity of the conduction band absorption of germanium due to the low effective mass of the electrons, intervalence band transitions in germanium, and the magnetic splitting of the conduction-levels in InSb The use of cyclotron resonance in determining the presence of excitons and in evaluating effective masses was also noted Crystal field effects in the spectra of inorganic complexes and the Davydov splitting in molecular crystals were also discussed

Dr J A Friend (Chemistry Department, University of Tasmania) and Dr Lyons have identified two transitions in the crystal spectrum of sodium nitrate, an allowed one at 2000 A and a weak n-π transition at 2870 A Dr J Ferguson (Division of Chemical Physics, Commonwealth Scientific and Industrial Research Organization) has analysed the polarized spectra of microcrystals of some cobalt (II) tetrahedral and octahedral complexes The absorption spectra of the tetrahedral complexes of the type $CoPy_2X_2$ are modified by intermolecular interaction in the crystal while the octahedral complexes can be interpreted by simple crystal field theory Mr J E A Alderson (Physics Department, University of Western Australia) discussed the luminescence spectra of thallium-doped potassium iodide in the spectrum range 600 A to 2500 A recorded on a normal incidence grating spectrometer with a photomultiplier as detector Dr L E Lyons, Dr J R Walsh and Mr J W White (Physical Chemistry Department, University of Sydney) presented the polarized visible spectrum of single crystals of phthalocyanine An attempt was made to calculate the crystal spectrum using the Davydov theory, but the error in estimating the dipole vector is too large to allow an unambiguous assignment of the crystal levels

Two papers on vacuum spectroscopic technique were presented One by Mr R S Crisp (Physics Department, University of Western Australia) described a grazing incidence, photon-counting grating spectrometer, working in the range 40–1000 A It has been found that the soft X-ray band emission spectra obtained with this instrument change with the material of the grating (aluminium to glass), with time, and with the order in which the grating is used These effects have no explanation at the moment J V Sullivan (Division of Chemical Physics, Commonwealth Scientific and Industrial Research Organization) described a double-beam photoelectric 1 m grating spectrometer, which has been tested down to 1500 A The monochromator employs a concave grating in a new type of mounting in which deviations from the Rowland circle lead to no detectable loss in resolution The double-beam system involves grazing incidence reflexion to split the exit beam and two electronically coupled photo-multipliers to record the spectra Examples of spectra recorded over the range 1500–6000 A were presented

The second day of the conference began with a review of some of the infra-red, Raman and microwave work of 1958 by Prof A N Hambly (Canberra University College) Topics discussed included accurate determination of molecular geometries from gaseous Raman and microwave spectra , information on torsional modes barrier heights, barrier tunnelling and rotational isomerism from spectra in the cæsium iodide and microwave regions , pressure-induced transitions in gases Perturbation effects and solvent effects need further study, for the reviewer pointed out that despite considerable work on the subject, the intensities of infra-red bands in polar solvents still do not accord with the theories

In a research paper Prof Hambly and J G Allpress (Chemistry Department, University of Melbourne) showed that infra-red spectra can be used to follow some solid state reactions They illustrated their remarks by showing spectra of the products of reaction between U_3O_8 and alkali or alkaline-earth halides They could detect differences that were not discernible in X-ray powder patterns

Dr E Spinner (Australian National University, Canberra) discussed the vibration spectra and structure of the hydrochlorides of urea, thiourea and acetamide Infra-red and Raman spectra suggest that the cations are formed by the addition of a proton to the nitrogen rather than to the oxygen atom and that the C—N bond in an amide is a pure single bond Drs N S Ham and J B Willis (Division of Chemical Physics, Commonwealth Scientific and Industrial Research Organization) dealt with the infra-red and Raman spectra of some isothiocyanates They have identified the symmetrical NCS stretching frequency in $—CH_2NCS$ types at about 670 cm.$^{-1}$, and at about 930 cm $^{-1}$ in aromatic —NCS compounds They also gave a detailed interpretation of the complex structure of the strong NCS characteristic band near 2100 cm $^{-1}$ A J Costoulas (Department of Chemistry, University of New South Wales) gave a complete vibrational assignment for methyl-isothiocyanate He agreed with Ham and Willis in the reassignment of the band at 676 cm $^{-1}$ to the symmetrical NCS stretching frequency

Prof A N Hambly and R H Laby (Chemistry Department, University of Melbourne) discussed some criteria for allocating displacements of X—H bond stretching frequencies to the formation of hydrogen bonds These are a double absorption band for weak intermolecular H-bonds and most weak intramolecular H-bonds, a double absorption band at low concentration in non-polar solvents for stronger intermolecular H-bonds, and a large displacement of frequency but no doubling on dilution for strong intramolecular H-bonds Some exceptions were illustrated by the spectra of some ortho-amino acetophenones and anthranilic esters The stable conformations of a series of methyl-*cyclo*-hexanols were reported by Dr A R H Cole and G T A Muller (Chemistry Department, University of Western Australia) Small but significant differences in the stretching frequencies of axial (3627–32 cm $^{-1}$) and equatorial (3622 5–23 cm $^{-1}$) hydroxyl groups were used to determine the conformations The methyl group was found to have a greater tendency to be equatorial than the hydroxyl group A G Moritz (Department of Organic Chemistry, University of Adelaide) has examined the overall appearance of the 3000 cm $^{-1}$ region in the infra-red spectra of a number of methyl-substituted polycyclic hydrocarbons He has confirmed the general applicability of the correlation between the pattern of this region and the free valence number of the position of substitution in the parent hydrocarbon, a correlation first observed by Fuson and Josien for the methyl-1 2-benzanthracenes

The results of a normal co-ordinate analysis of the 33 planar vibrations of naphthalene were presented by D E Freeman and Dr I G Ross (Physical

Chemistry Department, University of Sydney) An iterative procedure of adjusting the force constants was used to force agreement with seven of the frequencies the assignment of which is most certain This necessitates some reassignments, and the resultant interpretation is in general agreement with the work of Luther

The simplest molecule discussed at the conference was hydrogen deuteride the weak dipole vibration spectrum of which was the subject of a paper by Dr R A Durie (Coal Research Station, Commonwealth Scientific and Industrial Research Organization) The internuclear distance and the anharmonicity constants were calculated from measurements of the rotational structure of the (1,0), (2,0), and (3,0) vibration bands Dr D W Posener (Division of Electrotechnology, Commonwealth Scientific and Industrial Research Organization) presented the only paper on microwave spectroscopy He has measured the electric field gradients at the oxygen and hydrogen nuclei in HDO and D_2O and has begun a measurement of the magnetic hyperfine splittings

The following papers which were generally concerned with spectrographic apparatus and methods were also presented Dr H Gollnow (Mt Stromlo Observatory, Canberra) described a precision photoelectric setting device (accuracy about 0 5μ) for the measurement of diffuse spectral lines A fast-scanning infra-red (1–5μ) spectrometer equipped with a cooled lead–tellurium detector was described by Dr J Tregallas-Williams (Defence Standards Laboratories, Maribyrnong) Another paper from the same laboratories, by G L White, discussed the application of polynomials fitted by 'least squares' methods, instead of the Friedel–McKinney equation, for the calibration of infra-red spectrometers Some molecular spectra excited by shock waves were shown by Dr C L Cook (Weapons Research Establishment, Salisbury), and the part played by a photographic spectrograph in routine control in the steel industry was outlined by J H Savage (Australian Iron and Steel, Port Kembla) Another paper on emission spectroscopy was given by J M Nobbs (Defence Standards Laboratories, South Australia), who described some of the effects of pulse shape on the spectral characteristics of pulsed discharges He pointed out that the exponential shapes commonly used yielded lower sensitivities than most other shapes

The final morning session of the conference took the form of a small symposium on atomic absorption spectroscopy, with a review and five research papers on the subject A Walsh (Division of Chemical Physics, Commonwealth Scientific and Industrial Research Organization) reviewed the present status of emission and atomic absorption spectroscopy Recent advances in emission spectroscopy include better sources, the use of photomultipliers and the availability of vacuum instruments The use by Margoshes and Scribner of a plasma-jet as a spectroscopic source was a new development which will be followed with great interest However, the need for standards remains This results essentially from three types of interference, namely, chemical, radiative and excitative Atomic absorption spectroscopy avoids two of these but not the chemical interferences In the opinion of the reviewer the value of atomic absorption spectroscopy has been established and it seems that any analysis that can be done by flame emission methods using atomic lines can be done as well and often better by atomic absorption methods

J E Allan (Department of Agriculture, Hamilton, New Zealand) described the analysis of magnesium by atomic absorption The measurement is carried out simultaneously with flame emission analyses for calcium, sodium and potassium, the other major cations present in plants and soils The magnesium determination can be performed with the same ease as, and probably with greater reliability than, calcium, sodium and potassium determinations The minor elements zinc, iron and manganese have also been determined by atomic absorption directly on plant ash solutions or soil extracts, but copper at present requires prior extraction with an organic solvent D J David (Division of Plant Industry, Commonwealth Scientific and Industrial Research Organization) spoke about some of the chemical interferences encountered in applying atomic absorption to the analysis of plant material and soil extracts In plant material analyses, he finds no interference for zinc, iron, copper and magnesium but he finds that calcium absorption is depressed by phosphate, aluminium and silicate This interference is eliminated with 0 6 per cent magnesium ions and 2 per cent, volume/volume, sulphuric acid With soil extracts the atomic absorption analysis is straightforward for sodium, potassium and magnesium, but in this case the interference with calcium is controlled by 0 15 per cent strontium ions These two papers showed that many analyses important in plant and animal nutrition can be carried out successfully by the atomic absorption method

Dr J B Willis (Division of Chemical Physics, Commonwealth Scientific and Industrial Research Organization) discussed the determination of blood serum calcium and magnesium levels by atomic absorption Large quantities of strontium ions or the disodium salt of ethylene diamine tetracetic acid are needed to overcome the interference of phosphate and protein Duplicate measurements for calcium and magnesium can be made directly on about 0 25 ml of serum diluted 10–20 fold Dr P Brownwell (Botany Department, University of Adelaide) is interested in analysing for very small quantities (about 0 01 p p m) of sodium, which is a micronutrient for *Atriplex vesicaria* The flame photometric results are misleading when the calcium concentration exceeds 0 02 *M* The atomic absorption method using '*Si-ro-spec*', a simple instrument designed by Box and Walsh for this purpose, at present enables accurate measurements of about 1 p p m sodium in the presence of large excesses of calcium (4 *M*) and potassium

The final contribution, by Dr B M Gatehouse and Mr A Walsh (Division of Chemical Physics, Commonwealth Scientific and Industrial Research Organization), was concerned with the direct analysis of metals and alloys By sputtering from a metal surface in the presence of about 1 mm mercury pressure of neon they were able to obtain a calibration curve and to determine 1 p p m silver in a copper–silver alloy They suggested that this method may be suitable for elements such as aluminium and boron which do not give atoms in the flame

In a concluding discussion members agreed unanimously that a standing committee should be set up to organize similar conferences at regular intervals.

NORMAN S HAM

PROTEIN BIOGENESIS

A COLLOQUIUM on "Specificity in Protein Biogenesis" was held in Louvain during June 8–9 by the Centre interuniversitaire de Recherches enzymologiques, a government-sponsored association grouping several Belgian biochemical laboratories. The aim of the organizers was to bring together scientists actively engaged in research on protein synthesis and to establish new contacts with the Belgian groups interested in this field. The meeting was arranged on an informal basis and the speakers were asked to discuss freely the current work of their laboratories; the lectures will not be published.

Present ideas on the relationship between deoxyribonucleic acid and protein structures were lucidly summarized and discussed by C. Levinthal (Massachusetts Institute of Technology). Since deoxyribonucleic acid and protein are both linear polymers, it would seem that a simple relation should exist between the arrangement of the amino-acids in the protein and that of the nucleotides in deoxyribonucleic acid of the corresponding gene—probably a point-to-point correspondence between the two sequences. Some of the characteristics of the coding system serving to translate one sequence into the other can be deduced from what is known about deoxyribonucleic acid and protein structure. It seems feasible at present to check experimentally the idea of collinearity between the structure of the two types of polymers. Find an organism in which genetic maps can be established with great accuracy, choose an enzyme molecule of moderate size produced by this organism and devise a good selection principle for recovering the useful mutants. Isolate several mutants of the genetic locus of the enzyme, map the mutation sites, isolate the abnormal proteins, if any, which are produced in place of the normal enzyme by the mutants, and locate the differences within the protein molecules. This gives a test of the correspondence between deoxyribonucleic acid and protein fine structure.

C. Levinthal described the progress of his own work on the genetic control of the formation of a phosphatase in *E. coli*. Thirteen different mutants resulting from mutations within the locus of the phosphatase have been isolated so far; the linear order of the mutation sites has been established by a very interesting use of the transfer of genetic material during bacterial conjugation. Unfortunately only one of the thirteen mutants produced a recognizable modified phosphatase protein. Both the normal and the abnormal enzymes have been isolated, and their structure is now being studied. Future developments along this line of research will be watched with great interest.

In bacterial systems, genetic analysis is ahead of chemical knowledge. In man, on the other hand, where genetic analysis is at a great disadvantage, brilliant success has been achieved on the chemical side. J. Hunt (Cambridge) reviewed the main results obtained by the Cavendish Laboratory group on the structure of abnormal hæmoglobins. This work will undoubtedly become a classic of genetics and biochemistry. Hæmoglobins *S* and *C* differ from the normal protein in only one detail: the replacement of one glutamic acid in the β chain by valine or lysine respectively. Hæmoglobin *E* differs from normal hæmoglobin by the replacement of another glutamic residue by lysine; in hæmoglobin *G*, still another glutamic is replaced by glycine. Thus genetic differences presumably arising from mutations can result in the replacement of individual amino-acids at specified places in the polypeptides.

J. Hunt further described in detail his recent work on fœtal hæmoglobin. He has shown that one of the two polypeptide chains of fœtal hæmoglobin (chain α) is identical with that of normal adult hæmoglobin. This discovery opens new perspectives and will certainly give important information on the mechanism of the genetic control of protein structure, for here is a simple case of differentiation at the molecular level. The structure of fœtal hæmoglobin of infants carrying genes of abnormal adult hæmoglobins will be very informative. It might indicate whether the switch from fœtal to adult hæmoglobin during development results from the inhibition of the activity of a gene and the unveiling of another gene, or whether the change occurs somewhere between the gene and the protein-making system and consists in a change of expression of the same gene.

Other aspects of the control of the synthesis of specific proteins were discussed by B. Magasanik (Harvard University), who considered the phenomena of enzyme induction and repression and the function of ribonucleic acid in the synthesis of bacterial protein. B. Magasanik reported results obtained in his laboratory on various mutants which require amino-acids, nucleic acid precursors, or certain energy sources. By a very ingenious use of these mutants, several aspects of the correlation between ribonucleic acid content and level of protein synthesis were checked. Increased rate of protein synthesis goes together with an increased content of the bacteria in both soluble ribonucleic acid and ribosome ribonucleic acid. This is comparable to the well-known relation found in higher organisms. Studies on ribonucleic acid and protein synthesis during adaptation, especially in 'diauxie' experiments, indicate that the synthesis of new ribonucleic acid does not accompany enzyme adaptation. The results are compatible with a catalytic function of ribonucleic acid in protein synthesis, and with the view that induction and repression of enzyme synthesis rest upon the control of the activity of pre-existing protein-forming centres, rather than on the formation or destruction of such systems.

The existence of specific ribonucleic acid molecules capable of carrying some sort of genetic information is established by the discovery that pure virus ribonucleic acid is able to cause infection. Present knowledge on the structure of tobacco mosaic virus was summarized by H. Fraenkel-Conrat (University of California), who presented results of his current work on the molecular size of the virus ribonucleic acid. End-group determination in the virus acid by a combination of tracer methods with specific enzymic degradation and controlled chemical oxidation indicates that each virus particle might contain one single molecule of ribonucleic acid made up of some 6,000 nucleotides in one chain. The polypeptide chain of the virus protein contains only about 150 amino-acid residues. It would seem, therefore, that the ribonucleic acid of the virus is large enough to carry much more information than that which is required for controlling the primary structure of the protein unit contained in the finished virus This raises several problems for future research H Fraenkel-Conrat also reported very interesting results on a special state of the virus ribonucleic acid at the beginning of infection

Another approach to the specific function of ribonucleic acid in protein synthesis is the artificial modification of the structure of the acid This has been done by chemical means in the case of virus ribonucleic acid In bacteria, composition of the acid can be changed by growing the organisms in the presence of analogues of the normal purines or pyrimidines F Gros (Institut Pasteur, Paris) gave a very clear account of research on the effects of fluorouracil on protein synthesis in *E coli* Incorporation of all the individual amino-acids does not respond in the same way to fluorouracil For example, the incorporation of proline and tyrosine is depressed whereas that of arginine is stimulated These changes appear to reflect qualitative as well as quantitative modifications in the protein equipment of the organism, indicating that the analogue may actually interfere with the agents which control protein structure A phosphatase formed in the presence of the analogue has a normal enzymic activity although it contains less proline than the normal enzyme , thus it is probably slightly modified at a place which is not important for the catalytic properties of the protein On the contrary, β-galactosidase synthesis is abolished and replaced by the formation of some related inactive protein It is striking that fluorouracil specifically reduces the fixation of proline and of tyrosine on soluble ribonucleic acid at the same time as it reduces the incorporation of these same amino-acids into the proteins This indicates that soluble ribonucleic acid plays an important part in the specificity of protein formation These results also support current views according to which activated amino-acids are bound to soluble ribonucleic acid before condensing into polypeptides

T Hultin (Wenner Gren Institute, Stockholm) reported observations on animal tissues which indicate that another pathway of amino-acid incorporation might exist beside that passing through soluble ribonucleic acid That the latter must also be operative was shown by several of his results which agree with the classical scheme However, he obtained, by means of new techniques of isolation of ribosomes and by fractionation of supernatant preparations, a system in which amino-acids are incorporated into proteins in the particles in the absence of soluble ribonucleic acid A protein of the supernatant is required for incorporation with this system Protein synthesis which can occur in isolated mitochondria or nuclei appears to depend on the presence in these cell organelles of particles closely resembling the ribosomes of the cytoplasmic ground substance

Of great benefit to the meeting was the presence in the audience of biochemists from different countries who had taken part a few days before in Brussels in the Solvay Conference on Nucleoproteins All the lectures were followed by very good discussions The meeting was closed by a general discussion which concerned the function of the various ribonucleic acid fractions, the transfer of information from gene to protein, and coding problems

H CHANTRENNE

PROGRESS IN GAS CHROMATOGRAPHY

AN informal symposium of the Gas Chromatography Discussion Group (associated with the Hydrocarbon Research Group of the Institute of Petroleum) was held at the University of Bristol on September 25 under the chairmanship of Mr C S G Phillips

Dr F H Pollard commented on the enthusiasm and free interchange of ideas among workers in this field which was undoubtedly responsible for the present advanced state of the art Having regard to the success achieved by him in the field of inorganic separations by paper chromatography, it was not surprising that he should mention the possible separation of such materials by gas chromatography

The outstanding feature of the meeting was the demonstration by Mr R P W Scott of the presentation of gas chromatographic data with a high-persistence cathode ray tube With capillary columns it is possible to effect separations at speeds much greater than the response of conventional recorders, and in order to take full advantage of the technique in its application to kinetic and other studies a means of high-speed recording is essential Mr Scott, using a 70-ft column, demonstrated separations of 100° C boiling-range samples in less than 1 min with his apparatus which, inclusive of automatic repetitive sample injection system, cost less than £80 for materials

The discussion which followed a paper by Mr C L A Harbourn on quantitative determinations showed that this aspect of the subject is one that affects most users of the technique As yet, however, if one uses the published literature as a guide, it would appear to have received very little attention The well-prepared paper covered methods of peak measurement, sources of error and repeatability of calibration, internal standard, and normalization methods, and interpretation of unresolved peaks Recent developments in integrators and the use of analogue computers and tape recorders were also discussed

Some of the practical aspects of the measurement of retention volumes were dealt with by Dr G W A Rijnders, and Dr C R Patrick mentioned some of the problems attached to 'scaling-up' analytical columns to sizes capable of handling up to 10-gm samples The values of height equivalent of a theoretical plate (H E T P) increase and the much higher volumetric flow-rates necessitate modifications to the design of hot-wire detectors Mr D H Desty read a paper by Dr J Janak, who unfortunately was unable to be present, describing the application of gas chromatography to the identification of structure of involatile substances by pyrolysis and subsequent analysis of the products

Members attending, among whom were some from the United States and Europe, were able to inspect and see working a good selection of the commercial instruments now available for laboratory and process control work

C G SCOTT

ORIGIN AND DISPERSAL OF FLOWERING PLANTS

A TOTAL of no less than thirty-nine papers presented at the Montreal Ninth International Botanical Congress during August 19–29 dealt directly or indirectly with the origin and dispersal of flowering plants, providing a modern commentary on these two long-standing fundamental questions

A review of the evidence for a pre-Cretaceous origin was given in two invited papers before a joint symposium of the palæobotany and morphology and anatomy sections In the first of these A J Eames, discussing morphological testimony for a Palæozoic origin, maintained that studies in the Ranales showed that the primitive flower was bisexual and beetle-pollinated, that unisexuality and diœcism accompanied by insect pollination, then anemophily and the elaboration of simple sporophylls, were major advances which must have required long periods of time These steps had already been taken before the Lower Cretaceous Eames suggested that the search for ancestral angiospermous stock might again be directed towards the late Palæozoic ferns, even possibly the homosporous ones Besides the evidence from comparative anatomy, there was direct evidence in the form of pollen, wood and leaf impressions from the Triassic and Jurassic

L Van der Pijl opening the Darwin Centennial Symposium, considered that the angiosperm flower must have differentiated in contact with beetles, already present in the Permian, whereas insects are not common until the Cretaceous Persisting traces of beetle pollination, he pointed out, are found in extant groups V Grant, in an account of the diversity of pollination systems in the Polemoniaceae, appeared largely to concur with Van der Pijl's view of the primitive flower In different papers, A S Foster described how certain herbaceous ranalean forms might represent an early angiospermous type with dichotomous venation, W N Stewart proposed that Conrad's monophyletic classification of vascular plants be revived, despite the recent trend towards a polyphyletic one

The difficulties inherent in the discovery of palæobotanical evidence of angiospermous origins were illustrated by N H Hughes, who demonstrated Jurassic probably gymnospermous pollen, and by W G Chaloner, who described how carboniferous plants with spores which could be found occurring commonly could nevertheless be poorly represented as macro-fossils On the other hand, in a paper on Palæozoic marine sequences from New York and Australia, W R Evitt further documented the antiquity of vascular plant stocks

In the second invited paper of the first symposium D I Axelrod dealt primarily with a third line of evidence, namely, modern distribution patterns He illustrated with tables the preponderance of families entirely or largely tropical or with a large tropical section Basic distribution patterns which emerged were tropical, tropical and extra-tropical, boreal or austral, dry and temperate derived Such evidence, Axelrod considered, favours the supposed existence of angiosperms in the later Palæozoic in upland tropical regions where they underwent quantum evolution

Many biosystematic, palynological and palæological papers dealt to a greater or lesser extent with flowering plant distribution E Hulten, opening a symposium on alpigenous and arctogenous plants with specific illustrations of various types of circumpolar evolution, pointed out that increasing knowledge of this kind provided further material for Quaternary phytogeography W A Weber directed attention to the southern survival of many arctic and sub-arctic species, more especially in the Colorado Rocky Mountains E Dahl, considering amphi-Atlantic arctic-alpine plants, discussed evidence for their migration across a Pliocene or Pleistocene land-bridge Dahl suggested that the West Arctic Scandinavian species survived the last ice-age in coastal refugia rather than in Central Europe A Tolmatchev, in an abstract, stated that the Arctic flora was first formed in the Pliocene–Pleistocene, from indigenous elements in the treeless areas on mountain summits and slopes and similar open habitats T W Bocher held that most arctic or montane species groups are probably of Tertiary origin, but that considerable speciation occurred within these groups in the Quaternary, supported by geographical or genetical barriers J A Calder, discussing post-Pleistocene distributions in British Columbia, suggested that extensive refugia had existed in Alaska, the Yukon, also in the mountains of west Mackenzie and the Queen Charlotte Isles during the period of maximum glaciation

On modern montane distributions, K O Hedberg described the Afro-alpine flora as a complex derived from Mediterranean, Himalayan, South African and Temperate, besides Tropical African floras, and which had probably existed since the Miocene J K Morton found a higher incidence of polyploidy in the Cameroons mountain flora than in lowland Ghana, I Manton, in a presentation otherwise restricted to ferns, referred to this Cameroons flora as an "island" one, comparable with that of Ceylon in respect of the occurrence of polyploidy C Favarger described how the incidence of polyploidy in Switzerland in certain alpine groups coincided with a floristic subdivision G S Puri considered that during the Pleistocene glaciation the Himalayas were invaded by conifers, so that pure conifers or oak-conifer seral stages may now be found there alongside oak climaxes In an abstract B Pawlowski stated that there could have been many survivors of an endemic Tertiary flora on the east and some on the west of the Carpathians P Gorchakovsky similarly described how, apart from endemics, the Ural flora was composed of relics from pre-Glacial broad-leaved forests and glacial ones, from mountain steppe of Asiatic origin and from Pleistocene high mountain relics of Asiatic and of Siberian origin

Dealing with restricted aspects of modern temperate floras, A J Sharp thought that much of the flora of the newer coastal plains of Tennessee and the glaciated terrain to the north were segregates of a more ancient flora of the Southern Appalachian highlands L Laasimer divided the flora of Estonia into East Baltic, related to eastern Europe and West Baltic to Central Europe, respectively A A Beetle discussed how, in the southern part of central Wyoming, differences in grass distribution were due to differences in the age and origin of the various species In the Cretaceous, the Tethys Sea, by dividing the Old

World climates, established contrasts between the predominantly tropical panicoid and the predominantly temperate festucoid grass types Describing the phytogeography of Chinese species of *Fraxinus*, Shiu-Ying Hu stated that one species of a primitive group extended to Sumatra, two species from west and central China have close affinities with north American species, one from north China and one from Yunnan are close to European species

For tropical floras, A Liogier held that Cuba, although tropical, drew most of its species from subtropical and temperate North America The present Cuban distributions suggest that the bulk of the flora came chiefly from South America through Central America during the Mesozoic and Cainozoic, when Cuba and Jamaica were united with Honduras L B Smith described how the flora of south Brazil had its greatest source in central Brazil, there being continuous linkages with the Amazon, Andes and Argentine, discontinuous ones with the Amazon, North America, the Andes and Africa The mountainous and the low-lying floras of tropical America were considered by F Miranda to have had a greater diffusion in past Tertiary periods These floras were partially dominated later in tropical zones by a more macrothermic flora, and almost eliminated in North America by a more microthermic one

Papers were provided by K A Chowdhury, E Dorf, W L Fry, J Gray, T Jimbo and K Rasky, describing angiosperms in various Tertiary floras of India, Wyoming, Canada, Oregon, Japan and Hungary respectively C A Arnold and J S Lowther and J F Grayson and R L Pierce illustrated the low representation of angiosperms in two American Cretaceous floras L A Kuprianova described how palynological studies suggested that *Liquidambar* already occurred in the Upper Cretaceous, that it is not a typical representative of the Arcto-Tertiary flora, and indicated ancient floral relationships between the Mediterranean, Central America and Eastern Asia In a paper to the Taxonomy Section, J Ewan reminded botanists that zoogeographical data may prove illuminating in the interpretation of existing floristic patterns, citing examples including that of the wood rat which persists together with the relict Sierra Madrean flora on outlying Rocky Mountain summits A S BOUGHEY

THE NATIONAL HEALTH SERVICE IN BRITAIN

THE Acton Society Trust has produced a valuable survey of the National Health Service in Britain prepared by Sir George Schuster* Part of the report is a discussion of the general problems of leadership in a State service, this has been dealt with elsewhere (see *Nature*, October 10, p 1087).

Sir George then returns to the National Health Service itself He starts with two personal observations With keen appreciation of the achievements of the National Health Service in Britain in these first ten years, and the belief that too little was far better than too much interference from the central authority, he believes that the time has come for a general overhaul and tuning-up of the administrative machine, for an interpretation of the lessons to be learned from the practical experience of these first ten years, and for a new effort, in the light of this practical experience, to understand what is required to ensure that the National Hospital Service can meet the true needs, individual and social, of the people of Britain in these times Secondly, writing as one desperately anxious to see the best use made of this fine Service, he emphasizes the immense burden of current routine work now falling upon the senior staff of the Ministry This has left them with far too little time to attend to many of the things he suggests need to be done

This matter of overburdening the senior officials is not confined to the Health Service, and although its seriousness has often been admitted since the War, there is little indication that much has been done to relieve the situation All these, however, are matters that could bear closely on the work of other sections of the public service, where the administration of highly technical matters and the control of technical and professional staffs are involved It is to such major issues that Parliament might well have been expected to give its attention; but apart from Sir Keith Joseph's reference to the need for a research or planning staff in the Ministry, they were unnoticed in the House of Commons debate on the National Health Service on July 15

It is the quality of Sir George Schuster's thought and the character of his approach rather than his particular proposals that are of most general interest While he has always conceived of the hospital service as a great fighting service, in which the heads of hospital boards should be entitled to expect from the Ministry something like the leadership and direction which army commanders would get from their commander-in-chief and his general headquarters, he stresses the paramount importance of keeping the hospital service human Inadequate leadership, inefficient management, muddled organization can destroy all possibility of the workers in the service getting satisfaction from their work in a manner that keeps alive their enthusiasm and fulfils a sense of vocation This, however, is an essential element in providing what the patients themselves require above all—efficient curative treatment—and Sir George is well aware that good organization is only a means to an end and he reminds us that in the widest sense the welfare of the patients means taking into account their comfort, peace of mind and all the psychological and social implications of stays in hospital

Sir George does not devote space to the consideration of these issues He is content to note them among the great needs and opportunities in this service which call for a combination of hard-headed administrative efficiency, highly developed working skills, single-hearted pursuit of scientific knowledge and human kindness There are other fields in which the demands are no less, and even if in them it might be too much to assert that without human kindness the true purpose and value of the work must fail, without it full success or true efficiency are hard to achieve

---

* Creative Leadership in a State Service a General Survey (Hospitals and the State Hospital Organization and Administration under the National Health Service, Sixth and Final Research Paper) Pp iii+80 (London Acton Society Trust, 1959) 4s

Sir George believes, however, that a Government department can function as the directing authority of a great operating service like the Hospital Service in Britain, and the vast expenditure involved could not and should not be removed from the direct control of a Minister responsible to Parliament If, however, the Hospital Service is to remain the direct responsibility of a Minister and a Government department, Sir George considers that more attention must be given to the staffing of that department and to the arrangements for liaison between it and the decentralized formations, and that a central intelligence organization must be provided Further, he suggests that on all three points lessons can be learned from the experience of other Government departments which have responsibilities in relation to operating services

On the first point, he does not see how the Ministry can give the understanding leadership which is required unless the highest posts on its staff are held by officers who have had practical experience of hospital administration at operational level, and in support of his argument he quotes the staffing arrangements of the Fighting Service Ministries and of the Colonial Office Sir George pays tribute to the value of the work done by many officers appointed before such experience was available, and he does not advocate immediate wholesale change but rather exchanges of staff on the lines of the Colonial Office arrangements His stress is laid on the quality of the officers available to fill the various posts and the need in the National Hospital Service for new administrative skills, for which there is at present no readily available source of supply This last, as he recognizes, is a need which often occurs elsewhere to-day as a result of modern development, and the Hospital Service must take deliberate action to meet this need as private enterprise has done in the field of industry

It might be observed here that if this need for statesmanship is to be met in the Health Service, in industry, or elsewhere, those who meet that need must be treated as statesmen There is no place for the type of party politics which seeks to misrepresent opponents or those who may be entrusted with the execution of schemes or policies which are not in line with party doctrine It is significant that in supporting the Acton Society Trust's proposal that the Minister in charge of the Health Service should have a seat in the Cabinet, Sir George stresses the danger of frequent change of office, and his own proposals would make the chief permanent official in the Ministry a professional man

This does not mean that Sir George is here advocating that the expert should be permanently at the top , but his suggestion goes far beyond the claim that the expert should be considered for the highest administrative posts It implies that the expert by virtue of his expertise is particularly suited to supply the type of specialized administration needed He must, of course, possess administrative capacity there is nothing in Sir George Schuster's pamphlet to countenance incompetence in management or administration, but much to stimulate more thought about the way in which to meet the need for administrators and the type of training and experience they should receive

On the second point, that of liaison between the Ministry and the hospital authorities, Sir George suggests that there are lessons to be learned from the best traditions of the inspectors of schools under the Ministry of Education , but here again Sir George pleads for constructive thinking and refrains from specific proposals His stress on joint consultation at the centre and once again on the quality of the liaison officers clearly has implications far beyond the Health Service, and his strongest criticism is reserved for the perfunctoriness with which liaison is often treated Positive measures and constructive thought are always required to provide an effective two-way flow of ideas

Sir George Schuster's major proposal is in regard to his third point and, in line with a main recommendation of the Guillebaud report, he recommends the establishment of a central intelligence and statistical department This, however, should be an integral part of the executive, with its own creative role as a detector of problems and a productive source of wisdom Sir George has in mind something on the lines of the Office of Special Enquiries and Reports under the direction of Michael Sadler at the Ministry of Education, equipped with an intelligence staff which would keep under constant review the development of hospital practice, in its social as well as its medical setting, in Britain and other countries, and which would publish a series of reports which might be accepted throughout the world as authoritative With such a staff the Ministry could not only carry out its own investigations, but could also provide valuable stimulants to work by the hospital authorities Particularly in its social aspects, the research here required needs central guidance and co-ordination, and Sir George's own experience as chairman of a regional hospital board has convinced him of the great flow of evidence of clinical, human and social interest which requires recording, co-ordination and interpretation

Beyond this Sir George points to the need for creative thought, such as demands the services of men of wisdom and comprehension, combined with knowledge of medical affairs How to produce such men and women is one of the real challenges which this rapidly changing world makes on professional organizations to-day, and there is much indeed in Sir George Schuster's comments that deserves careful study by professional men and women of professions other than that of medicine So far as the National Health Service in Britain is concerned, Sir George Schuster's investigation suggests that this is very seriously understaffed as regards first-class administrators in comparison with large industrial organizations, and some improvement here may well be the first step required to implement his more specific proposals to remedying the alleged weakness of the voluntary committee system and to promote the intensive expert study of the hospital cost structure, the full use of efficiency techniques by the hospital authorities, including the introduction of work-study methods, and the application of operational research to some of the problems of the hospital service

These last are clearly proposals limited specifically to the Hospital Service and to some of them an interested group of members of Parliament is already giving attention The Minister of Health has stated that the Ministry's present experimental organization and methods unit is to be enlarged and made permanent, and that he has accepted the offer of a group of management consultants to undertake a series of surveys, at their own expense, to demonstrate the economies and improvements in efficiency which could be achieved in the hospital service by work study

PREVENTING JUVENILE DELINQUENCY

SEVERAL years ago the United States Children's Bureau, as part of its programme on juvenile delinquency, published a report about the effectiveness of measures in delinquency prevention The analysis was based on evaluative studies conducted over the previous twenty-five years or so

The review led to the conclusion that programmes for the prevention of juvenile delinquency had not been notably effective This conclusion was tempered by two facts First, few programmes, relatively speaking, had been evaluated, and most of those not adequately Secondly, many of the evaluative studies were out of date since they dealt with programmes and methods that to-day might not be considered the best Moreover, there were hints that good results had been achieved with certain types of delinquent children in certain circumstances This was notably the case in child guidance work and was perhaps also true of the kind of neighbourhood work associated with the name of Clifford Shaw

Some of the newer programmes and methods seemed, however, to give promise of more favourable findings Among those mentioned in the report were various devices for 'reaching out' to youngsters and their parents with services they were unlikely to seek for themselves , for example, group work with delinquent and predelinquent gangs, case work or group work with 'resistant' families These and other newly devised programmes seemed to be succeeding where older ones had failed and to be benefiting both from the experience of their predecessors and from recent advances in knowledge about human behaviour and motivation

In an issue of the *Annals of the American Academy of Political and Social Science*, measures of delinquency prevention and their effectiveness are continued with reports from practitioners and research workers who have been closely associated with these efforts (322, March 1959)

The most striking change, according to Helen L Wilmer, of the U S Department of Health, Education and Welfare, is in the level of sophistication shown in the reports This is shown in the way the work with delinquent youngsters and their parents is carried on, in the psychological and sociological knowledge underlying the work, and in the methods employed in its evaluation Much has been learned in all these areas in recent years These articles show programmes of delinquency prevention both benefiting from that advance and contributing to it

Perhaps the most important contribution of this series of articles lies in the picture it provides of the kinds of young people who are likely to become chronically delinquent and of the kinds of homes and neighbourhoods they live in The picture is not a new one but is drawn in a way that reveals, more vividly than usual, the fears, the discouragement and the wish to be like other people that characterize these young people and their parents The treatment measures described, both those that would improve the environment and those that are directed toward the individuals, take their direction from this knowledge The knowledge itself is rooted both in the social sciences and in psychology and demonstrates their interrelatedness

The articles deal with small programmes and, in part, short-lived efforts Few of them report scientifically established results Nevertheless, in their conception of what needs to be done and in their suggestions for some ways of doing it, they hold the hope that the problem of delinquency can be reduced if communities are willing to put the effort required into the work

THE ORIGINS OF LOVE

PSYCHOLOGISTS, sociologists and anthropologists commonly hold the view that the infant learns to love through the association of the mother's face, body and other physical characteristics with the alleviation of internal biological tensions, particularly hunger and thirst Psycho-analysts have tended to emphasize the importance of attaining and sucking at the breast as the basis for affectional development Recently a number of child psychiatrists have questioned such simple explanations Some argue that affectionate handling in the act of nursing is a variable of importance, whereas a few workers suggest that the composite activities of nursing, contact, clinging and even seeing and hearing work together to elicit the infant's love for his mother

It is difficult, if not impossible, to use human infants as subjects for the studies necessary to break through the present speculative impasse For several years a group at the Primate Laboratory of the University of Wisconsin has been using baby rhesus monkeys in a study that has begun to yield significant insights into the origin of the infant's love for his mother A report has been prepared by Harry F Harlow*

The interest in infant-monkey love grew out of a research programme that involved the separation of monkeys from their mothers a few hours after birth The investigators were impressed by the deep personal attachments that the monkeys formed for the diaper pads, and by the distress that they exhibited when the pads were removed briefly once a day for the purposes of sanitation The behaviour of the infant monkeys was reminiscent of the human infant's attachment to its blankets, pillows or rag dolls These observations suggested a series of experiments to compare the importance of nursing and all associated activities with that of simple bodily contact in engendering the infant monkey's attachment to its mother Two surrogate mother monkeys were prepared One is a bare welded-wire cylindrical form surmounted by a wooden head with a crude face In the other the welded wire is cushioned by a sheathing of terry-cloth Eight new-born monkeys were placed in individual cages, each with equal access to a cloth and a wire mother Four of the infants received their milk from one mother and four from the other, the milk being supplied in each case by a nursing bottle, with its nipple protruding from the mother's 'breast'

---

* *Scientific American* 200, 6, June 1959.

The two mothers quickly proved to be physiologically equivalent The monkeys in the two groups drank the same amount of milk and gained weight at the same rate But the two mothers proved to be by no means psychologically equivalent Records showed that both groups of infants spent far more time climbing and clinging on their cloth-covered mothers than they did on their wire mothers As the monkeys grew older, they tended to spend an increasing amount of time clinging to and cuddling her pliant terry-cloth surface Those that secured their nourishment from the wire mother showed no tendency to spend more time on her than feeding required, contradicting the idea that affection is a response that is learned or derived in association with the reduction of hunger or thirst These results indicate the importance of bodily contact and the immediate comfort it supplies in forming the infant's attachment for its mother, the cloth-covered mother surrogate is an eminently satisfactory mother

The time that the infant monkeys spent cuddling on their surrogate mothers was a strong but perhaps not conclusive index of emotional attachment Would they also seek the inanimate mother for comfort and security when they were subjected to emotional stress ? With this question in mind the monkey infants were exposed to the stress of fear by presenting them with strange objects, for example a mechanical teddy bear which moved forward, beating a drum Whether the infants had nursed from the wire or the cloth mother, they overwhelmingly sought succour from the cloth one, this differential in behaviour was enhanced with the passage of time and the acquisition of experience All tests show that the infant monkey's relationship to its surrogate mother is a full one Comparison with the behaviour of infant monkeys raised by their real mothers confirms this view

While bodily contact clearly plays the prime part in developing infantile affection, other types of stimulation presumably supplement its effects A search has been made for these factors Western culture parents appreciate that rocking a baby or walking with him somehow promotes his psychological and physiological well-being The responsiveness of infant monkeys to two cloth mothers, one stationary and one rocking, was now compared All preferred the rocking mother, though the degree of preference varied considerably from day to day and from monkey to monkey Motion does appear to enhance affection, albeit far less significantly than simple contact The act of clinging, in itself, also seems to have a role in promoting psychological and physiological well-being

Still other elements in the relationship remain to be investigated systematically The warmth of the mother's body would appear to play its part in strengthening the infant's ties to the mother Observations have not yet confirmed this hypothesis Heating a cloth mother does not seem to increase the attractiveness of the mother to the infant monkey and infants readily abandon a heating pad for an unheated mother surrogate Visual stimulation may forge an additional link It is also possible that particular sounds and even odours may play some part in the normal development of response or attention

The depth and persistence of attachment to the mother depend not only on the kind of stimuli that the young animal receives but also on when it receives them Experiments with ducks show that imprinting is most effective during a critical period soon after hatching, beyond a certain age it cannot take place at all From preliminary experiments with monkeys it has been found that their affectional responses develop, or fail to develop, according to a similar pattern

NORTH–SOUTH ANISOTROPY AND ANTICIPATORY INCREASE OF INTENSITY ASSOCIATED WITH THE COSMIC-RAY STORM OF FEBRUARY 11, 1958

By Dr V SARABHAI*

Physical Research Laboratory, Ahmedabad, India

THE time variations of cosmic rays have been measured during the International Geophysical Year with standard instruments at a large number of places on the Earth, and several studies have been made of the energy dependence of the primary variations and the anisotropy which is often associated with primary variations of intensity From an examination of Forbush-type decreases, Fenton, Fenton and Rose[1] have come to the conclusion that the cause of the transient intensity decreases is variable in its energy dependence from a few BeV to more than 30 BeV The variation in response to transient decreases observed with similar equipment at different stations suggests that a primary anisotropy is present at these times Lockwood[2] has examined the detailed structure of several Forbush-type decreases in the intensity of local neutrons during 1955–58 He finds that in most of the decreases there was a magnetic storm at the onset Flare activity during the preceding 30 hr was high and there was some indication of an intensity maximum during the 12-hr period preceding the start of the decrease He comments that such an anticipatory effect might be due to the albedo of the moving magnetic gas cloud, but that further results are

			0126	$-\Delta H$, $-\Delta C$	(2) Decrease starts at high latitudes
			0130	Aurora	
			0154	$+\Delta H$, $-\Delta C$	
			0300	CR minimum	(3) 0300 minimum at equator
					(4) 0500 minimum in mesons
			0622	X-ray $\Delta H = 0$	
			0635	Maximum absorption, galactic noise of 18 Mc /s	
					(5) 0700 minimum at high latitudes
			0730	X-ray ends	
			0850	X-ray and ΔH	(6) Increase commences
			1000	Maxima aurora	Seen in instruments with high and low energy response Not observed in stations in 120° E belt, nor in the southern hemisphere
			1100	CR maximum	

needed to substantiate any anticipatory effect McCracken and Parsons[3] have made a very interesting analysis of a Forbush-type event which occurred on October 21, 1957 They found that there was a preliminary depression prior to the commencement of the Forbush decrease and they comment that it was not due to the arrival of solar matter at the Earth since it occurred before the magnetic disturbances They conclude from studies made at several stations that the preliminary depression must be attributed to a cause located at some distance from the Earth, and since it is not observed simultaneously at all stations its explanation requires some rather special form of short-lived primary anisotropy McCracken[4] has analysed the anisotropy of a number of Forbush-type decreases which were preceded by decreases Yoshida and Wada[5] have directed attention to increases of intensity which occur after the onset of cosmic-ray storms They believe that the increases are mainly isotropic and have an energy-dependence nearly the same as that of the decreases.

In connexion with the Forbush-type decrease in cosmic-ray intensity which occurred on February 11, 1958, we have fortunately a large number of other solar and terrestrial observations which give us a unique set of data for following the event from the time it occurred on the Sun These have been summarized by Trotter and Roberts[6] During its second passage on February 9, 1958, a region 58-*B* at 15° S heliographic latitude, then at the central meridian, suddenly underwent very rapid changes in plage brightness and sunspot growth The region flared rapidly throughout the day, half a dozen of the flares were Class 1+ or greater Five of these caused complete short-wave radio fade-outs of considerable duration In addition, these events were associated with unusual solar radio noise burst activity on 2,800, 470 and 167 Mc /s The flux density on 167 Mc /s was very high during February 7–9 An extremely large number of high-speed dark surges were observed on the solar disk, most of them in association with small flares The mean integrated coronal (5303 A) intensity was low during the period Region 58-*B*, which had very intense activity during the second passage in February, persisted with pronounced activity during the third and fourth passages in March and April respectively

The strongest geomagnetic storm with sudden commencement (s c) of the present solar cycle began early on February 11, and almost simultaneously a very spectacular aurora that persisted throughout the night lit up the northern sky as far south as the 35th parallel It was visible on the following night as well. In Table 1, the important events observed on the Sun and on the Earth are summarized in chronological order

We have examined the effect in cosmic rays from data of the high counting-rate meson detector at the Massachusetts Institute of Technology and from a grid of neutron monitor stations distributed (1) in two belts corresponding to the equator and the middle geomagnetic latitudes, (2) in three meridional sections corresponding to 75–115° W, 0–32° E and 147–168° E , and (3) in the northern and southern hemispheres In Table 2 are indicated the stations which are included in the grid, particulars of their location and the name of the principal investigator at each station through whose kindness the data have been made available to us Assuming that the variations can be dependent on the primary energy response, on local time or longitude and on the hemisphere, we have grouped stations so as to study one variable at a time with, so far as possible, an equal contribution in each group due to the other two variables The stations from which data have been combined for the various analyses are indicated in Table 2

Fig 1 shows the percentage deviations in the bi-hourly counting-rates of the neutron monitors during successive bi-hourly periods in U T from February 9–12, the deviations in each case being taken with respect to the mean intensity on February 10, which represents a period of 24 hr immediately preceding the onset of the Forbush decrease early on February 11 It is clear from Fig 1*A* that the variation is strongly dependent on primary energy It will be noticed that the meson detector at the middle latitude exhibits a variation which is intermediate between the variation of the neutron monitor intensity at the equator and at the middle latitude stations The middle latitude stations have a much larger percentage decrease than the stations at the equator A minimum intensity is reached at 0300 U T , at 0500 U T and at 0700 U T at the equator, with the meson detector and at the middle latitude stations respectively Moreover, about 12 hr. after the initial decrease, at the equator the intensity returns almost to normal before it decreases again , on the other hand, the recovery occurs only partially at middle latitude stations

A most interesting aspect of the present event is the increase of intensity at 2100 U T on February 10, observed at equatorial stations only, about 4 or 5 hr before the arrival of the solar plasma at 0120 U T , indicated by the storm with sudden commencement and a number of other terrestrial effects The second increase, or the recovery of intensity at 1100 U T on February 11, is seen to be much more significant at the equatorial stations and in the meson detector at Cambridge than at the middle latitude stations It would thus appear that both events, which appear to be increases, are particularly characteristic of the high-energy component of the primary radiation In contrast, the first minimum of the Forbush event is larger and occurs later for low-energy than for high-energy primaries

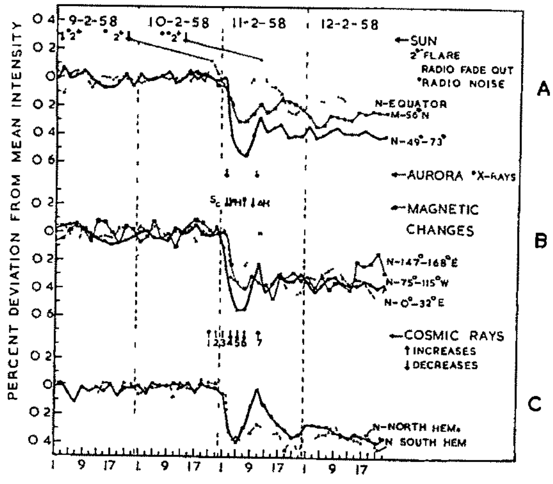

Fig 1 Cosmic-ray intensity changes and associated solar and terrestrial effects for the cosmic-ray storm of February 11, 1958 Relationships of changes are indicated separately in *A* for low and medium latitudes and primary energy response, in *B* for meridional sections and in *C* for hemispheres

In Fig 1*B* the variations of intensity at stations in the three meridional belts are compared It is seen that there are significant differences in the initial decrease, indicating the existence of an anisotropy The most remarkable feature is the complete absence of the second increase at 1100 U T on February 11 at stations in the east meridional section (147° E to 168° E longitude), as also at stations in the southern hemisphere for which a comparison with the northern hemisphere is shown in Fig 1*C* The second increase of intensity is thus characterized by a strong anisotropy not only parallel to the ecliptic, but also perpendicular to it This is perhaps the first evidence for an anisotropy of the latter type In contradiction to the view of Yoshida and Wada, we believe that the second increase is mainly anisotropic and has an energy dependence different from the mainly isotropic Forbush decrease

The main event observed early on February 11 in cosmic rays, in geomagnetism, in the aurora and in X-rays at high altitudes is undoubtedly related to the major solar outburst from region 58-*B* between 2053 and 2139 U T on February 9 We would like to suggest here that solar plasma reached the interaction distance of the geomagnetic field at about 0120 U T on February 11, but that for several hours prior to that, there was a cosmic-ray effect which involved an increase of the radiation During the second increase of cosmic-ray intensity on February 11, we have an increase of cosmic-ray intensity occurring with a strong aurora and change of the horizontal component *H* of the geomagnetic field This contrasts with the association of the aurora and the change in magnetic field with the large decrease of cosmic-ray intensity about 10 hr earlier From other geophysical evidence it is believed that the main plasma outburst streamed past the Earth in 10–12 hr and it appears that the second increase of cosmic-ray intensity is related to the departure of the plasma cloud There was a 2^{+} flare with major burst of radio noise at 67° W heliographic longitude, which occurred at 1325 U T on February 10 It is worth while examining whether the second increase is related to the arrival of fresh solar particles from this flare If, in order to explain the terrestrial influence of a solar event far removed from the central meridian to the west, one postulates the presence of a guiding path of solar magnetic lines of force stretched out to the Earth by earlier streams or an outward solar wind, it would be difficult to explain the 24-hr delay for solar particles of even a few MeV energy We are thus inclined not to associate the second event with the solar outburst on February 10

We believe that in the two increases and the main decrease observed with the cosmic-ray storm of February 11, 1958, we have essentially three types of modulation process One is directly associated with the moving plasma, probably related to the magnetic fields in the shock front and gives increases as well as decreases of intensity along with anisotropy The second gives decreases of intensity and is related to a process which has a sharp onset but a relatively long time constant of recovery The first is often more effective for high primary energies than low, but the second is much more effective for low than for high energies

The large anisotropy parallel to the north–south and east–west directions in the second increase poses an important problem The different motions of solar particles trapped by the geomagnetic field have been discussed by Gold[7], and before average conditions are established round the globe there is probably a basis for major differences in conditions over the hemisphere and at different meridional sections immediately following the arrival of a new cloud of solar particles But the time involved is very short compared to the observed effect which shows up over periods of several hours Moreover, even though changes in the Van Allen radiation belts could perhaps provide an adequate mechanism for the perturbation of the geomagnetic field, and through it alter cosmic-ray intensity, a quantitative evaluation of the effect has not so far been undertaken

We are grateful to Mr S R Thakore and to the computation section at the Physical Research Laboratory and to Miss Britt at the Massachusetts Institute of Technology for help in analysing data One of us (V S) wishes to express gratitude for the hospitality of the Laboratory for Nuclear Science, Massachusetts Institute of Technology, and for financial assistance from the Department of Atomic Energy of India The work at the Massachusetts Institute of Technology has been assisted by the joint programme of the Office of Naval Research and the U S Atomic Energy Commission, and one of us (R P) is supported by a fellowship of the Conselho Nacional de Pesquisas, Brazil, which are gratefully acknowledged We have had many stimulating discussions with B Rossi and T Gold

MEASUREMENT OF THE EFFECTS OF PISTON MASS AND BURSTING PRESSURE ON THE MOTION OF A PISTON IN A HYPERSONIC GUN TUNNEL

By B J BELCHER

Department of Aeronautics, Imperial College of Science and Technology, London, S W 7

A HYPERSONIC gun tunnel[1] is essentially a blow-down tunnel with a shock compression heater to generate a high-temperature reservoir of gas This heater consists of a high-pressure vessel separated from a long barrel by a diaphragm and light piston (see Fig 1) When the pressure is high enough the diaphragm bursts and drives the piston down the barrel A shock wave forms ahead of the piston and is reflected from the almost closed nozzle end of the barrel, causing several compressions of the gas within the barrel and raising the temperature The piston finally comes to rest with the pressures on both

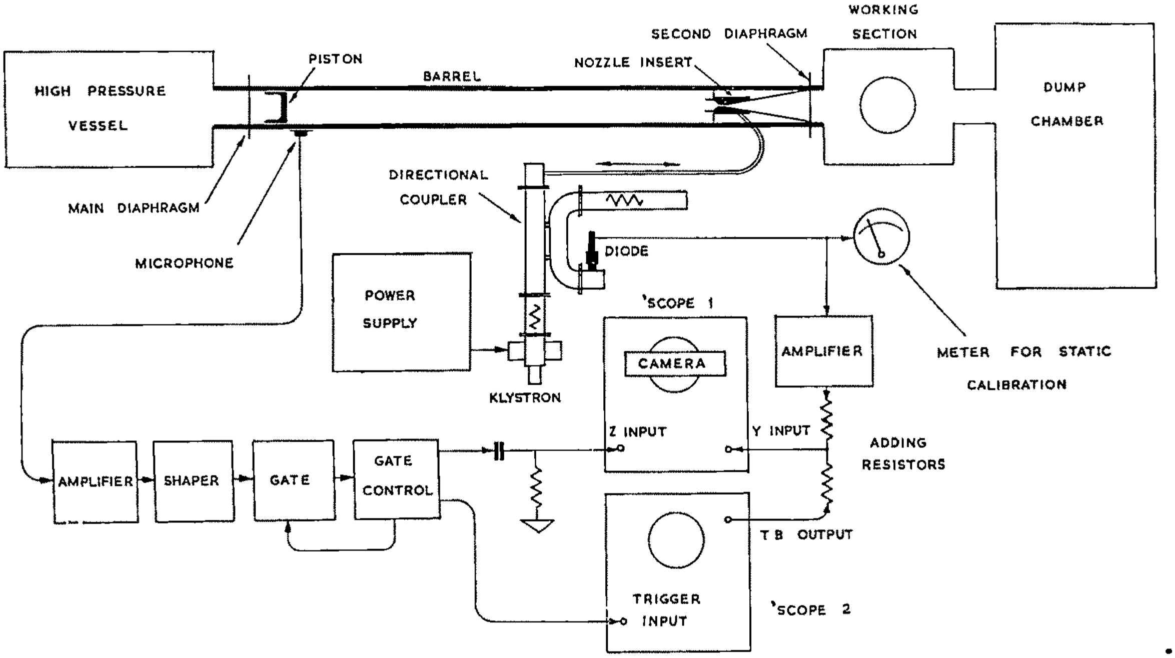

Fig 1 Layout

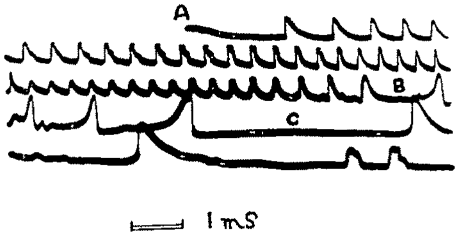

Fig 2 Typical oscilloscope record

sides equal Both the mass of the piston and the bursting pressure will affect the performance of the tunnel

One of the investigations into the operation of the gun tunnel at the Imperial College of Science and Technology, London, was to find how the bursting pressure and piston mass affect the motion of the piston down the barrel This was done by a microwave technique[3], the barrel being turned into a long resonant cavity by coating the face of the piston with a conducting material, either a silver colloid paint or by gluing and screwing on a dural disk Microwaves are injected at the nozzle end and resonance occurs with the piston at every half wave-length By detecting and recording these resonances an analysis of the piston motion is possible

The generator is a 200-mW , 10-cm klystron feeding a wave-guide directional coupler To reduce the tendency for the klystron frequency to follow the changing resonant frequency of the barrel cavity, an attenuator is inserted between the klystron and the directional coupler The purpose of the directional coupler is to sort out signals according to their direction, so that only the reflected waves coming from the barrel reach the diode Power is fed from the klystron to the probes mounted in the nozzle insert through a co-axial cable These probes are arranged not to interfere with the normal working of the tunnel while still exciting a radially symmetric mode (TM_{01}) in the barrel During a run the probes are protected by a nylon block The probes are matched to the barrel cavity so that under conditions of resonance there is little power reflected back along the co-axial feeder However, when the piston moves from the resonant position the subsequent mismatch causes power to be reflected and is detected by the diode on the directional coupler Hence a resonant point is indicated by a drop in the voltage output from the diode The drop in voltage is recorded by an oscilloscope and camera About fifty resonant points have to be measured and, as one sweep of the cathode ray tube has insufficient resolution, a raster type of display was used with a second oscilloscope providing the vertical time-base Oscilloscope 1 was arranged to sweep continuously but with the beam blanked off, and oscilloscope 2 brightened up the first beam when triggered from a bursting signal picked up by a microphone The time-base from the second oscilloscope was then added to the diode output to displace consecutive lines on the recording tube, producing a raster display. One trouble encountered was that the time-base voltage biased off the diode and reduced the signal to nothing This was cured, with the attendant advantages of a larger signal, by inserting a small self-contained transistor isolating amplifier between the diode and the adding resistors (see Fig 1) The amplifier has a voltage gain of 17, a frequency response of 15 c /s to 500 kc /s ± 3 db with a high input and low output impedance Two *OC* 45 transistors are used A similar amplifier was also used as a microphone amplifier Because of the resulting 'ring' and general noise of a burst, several traces were superimposed for each run as the second oscilloscope triggered more than once To ensure that only one trace was obtained a trigger and gate system was adopted This amplifies and shapes incoming signals from the microphone and passes them to a gate A pulse coming from this gate closes the gate

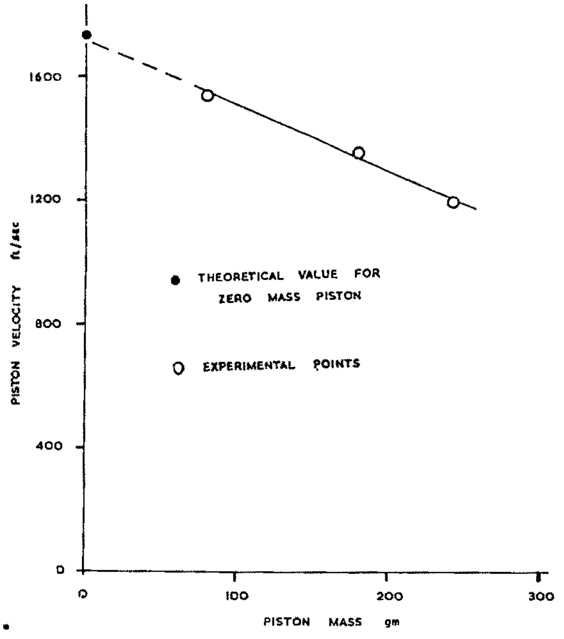

Fig 3 Variation of piston velocity with mass

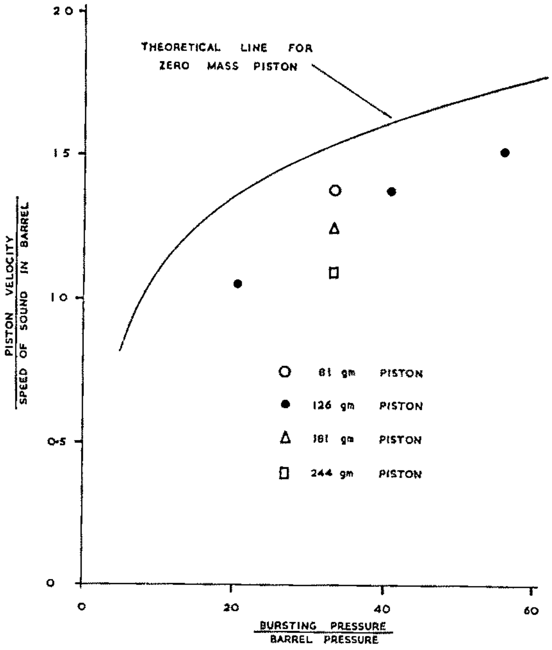

Fig 4 Variation of piston velocity with bursting pressure

and triggers the second oscilloscope Hence only one trace is possible before the system is reset by opening the gate manually

A typical record is shown in Fig 2 Starting at A, which is arranged to be on a resonant point for reference, the distance between pips becomes less, indicating acceleration of the piston, until the third line down where after a rapid deceleration the waveshape is seen to reverse, at B, indicating that the piston has reversed and is now going the other way down the tube On the fourth line at C another reversal is evident The resonant points are indicated by positive pips because the amplifier reverses the sign of the signal

These film records were analysed to give a plot of piston position (x) against time (t) From such plots the maximum piston velocity is taken. Figs 3 and 4 summarize these results Initial acceleration was also measured from the x–t plots assuming the acceleration to be constant over the first few stations, the results being

Bursting pressure (lb /sq in)	Acceleration
300	4,000g
485	5,400g
600	7,200g
825	15,000g

I am indebted to Mr J L. Stollery for his direction and help in the foregoing work, and to Mr P D. Church for his analysis of the traces

A STRUCTURAL MODEL FOR MONATOMIC LIQUIDS INCLUDING METALLIC LIQUIDS

By Dr KAZUO FURUKAWA

Research Institute for Iron, Steel and Other Metals, Tohoku University, Sendai, Japan

ALTHOUGH the melting point (T_m) is generally determined thermodynamically, it is interesting that Lindemann's geometrical law[1] is effective in determining the melting condition of solids So we have studied the structure of liquids at their melting points in the hope of finding some similar law

So far, radial distribution curves for 18 monatomic liquids near their melting points have been obtained by X-ray or neutron diffraction measurements, and they give co-ordination numbers (Z) and the distance (r_1) of the nearest neighbour However, the values of Z so far obtained are less reliable than those of r_1, it is probable that in some cases we obtained low values Therefore, we calculated Z from r_1 and the bulk density (measured) assuming a quasi face-centred cubic lattice The calculated values Z_{cal} were between 10 and 11 5 (mean value 10 85, about 90 per cent of 12 Table 1)

The shape of the curves was analysed by Wall's theory[2] using the spherical free volume of radius σ According to this theory, $(r_1 - \sigma) = A$ corresponds to the position on the shorter side-branch at a height of 34 4 per cent of the maximum value in the first peak of the curve $4\pi r\rho(r)$, where $\rho(r)$ is the atomic number density at a distance r from any atom Hence we measured A_{ob} from radial distribution curves, and obtained the empirical formula $r_1/A_{ob} = (1\ 5)^{1/3}$ (Table 1)

Assuming a molecule to be a sphere (nearly rigid)[2] of diameter A at T_m, the following model can be postulated Let V_0 be the volume at closest packing of spherical molecules of diameter A, then the volume of liquid at T_m is 1 5 V_0 for quasi face-centred cubic lattice But about 10 per cent of the sites in this quasi-lattice are empty, and these spaces are distributed through all interstices, explaining the second peak at 1 9r_1 of the distribution curves Thus the total volume is about 1 65 V_0

Using this model of a reduced form independent of materials, several properties of liquids can be explained as follows Self-diffusion and viscous flow in liquids are easily explained The self-diffusion coefficient of a liquid at its melting point may be expressed[3,4] as $D_m = \gamma\, r_1^2\, \nu_m \exp(\Delta S_D/R) \exp(-H_D/RT_m)$, where $\gamma\, r_1^2$ is the mean square of jump distances, ν_m the frequency of the liquid at T_m and ΔS_D and H_D the activation entropy and energy of diffusion respectively Now γ, ΔS_D, H_D/RT_m and $D_m/(r_1^2\ \nu_m)$ must all be constants independent of the material If ν_m is calculable from Lindemann's formula, $\nu_m = 2\ 8 \times 10^{12}\, T_m^{1/2}\, M^{-1/2}\, V_m^{-1/3}$, where M is the molecular weight and V_m the molar volume, $D_m/(r^2_1\, \nu_m)$ is obtainable from experimental values of D_m, and is nearly constant (Table 2)

The experimental values of H_D/T_m and $H\eta/T_m$ are also nearly independent of the material, where $H\eta$ is an activation energy of viscosity (Table 2) Differences between the liquid metals and other material may be explained by the expansion co-

Table 2 SELF-DIFFUSION AND VISCOSITY DATA (C G S)

(*a*) See ref 12 concerning the experimental values of D_m (*b*) Careri and Paoletti, *Nuovo Cim* , II, No 3, 574 (1955) (*c*) Yang, Kado and Derge, *Trans Met Soc A I M E* , **212**, 628 (1958) (*d*) "Liquid Metal Handbook" (1952) (*e*) Culpin, *Proc Phys Soc* , B, **70**, 1069 (1957) (*f*) Gebhardt and Wörwag, *Z Metk* , **42**, 358 (1951) (*g*) Rudenko and Schubnikow, *Phys Z Sowjet* , **6**, 470 (1934) (*h*) *ibid* , **8**, 179 (1935) (*i*) Grunberg and Nissan, *Trans Farad Soc* , **45**, 125 (1949) (*j*) Thorpe and Rodgen, *Phil Trans Roy Soc* , A, **185**, 397 (1894) (*k*) See ref 6

efficients the ratio of which is of the order of 10^{-2} In fact under the condition of constant volume H_D/RT_m becomes 2 14 for CCl_4[5], and 1 26 for C_6H_6[6], from isobaric experiments, and becomes 2 07 for Hg[4], 1 63 for Ga[4], 1 65 for CCl_4[5] and 1 40 for C_6H_6[6] by computation from isothermal experiments using[6] their expansion coefficients and compressibilities

So putting $H_D/RT_m \equiv 1\ 6$ at constant volume, we obtain $\Delta S_D/R = -\ 3\ 1 \pm 0\ 3$ independent of the materials from their values $D_m/(r_1{}^2\ \nu_m)$ of Table 2 $\Delta S_D < 0$ can easily be explained by a more regulated activated-complex configuration composed of planar 4 or 5 atoms in the closest contact than the ordinary irregular configurations Considering the above, it is of interest that *A* nearly coincides with the metallic bond-lengths of co-ordination number 3 calculated by Pauling's theory[7] (*r* (3) in Table 1)

Combining these facts with the Sutherland–Einstein formula[8], $D\eta = kT/(2\pi A)$, we can easily deduce Andrade's formula[9] $\eta_m = 5\ 7 \times 10^{-4}\ M^{1/2}\ T_m{}^{1/2}\ V_m{}^{-2/3}$ putting $D_m/(r^2{}_1\ \nu_m) = 0\ 0067$ The calculated viscosity coefficients at T_m, $\eta_{m,cal}$, are in good agreement with the experimental values $\eta_{m,ob}$ (Table 2)

Moreover, using Wall–Harasima's free volume theory[2,10], and adding the entropy of random arrangement of vacancies as a cruder treatment of this model, the entropies of the liquids at their melting points were calculated , the values agreed with the observed ones (Table 3)

The above discussion shows that the metallic liquid is not a special liquid Thus we need not consider the ionic unit[4,11,12] in the transport phenomena

The model will become more complete when combined with the recent work of Bernal[13], who explained the essential difference between regular and irregular close-packing arrangements having a volume difference of about 10 per cent, which agrees with our model

A detailed description including further applications will be published elsewhere

POLYNUCLEAR COMPLEXES OF MOLYBDENUM(II)

By DR J C SHELDON

William Ramsay and Ralph Forster Laboratories, University College, London, W C 1

ALTHOUGH molybdenum(II) chloride and its co-ordination complexes have been known for a century, they have received but little attention As a result of the virtual absence of physical studies on these compounds, not only was nothing known of their constitution until a few years ago, but incorrect molecular formulæ were even adopted The relatively recent X-ray diffraction studies by Brosset[1–3] have done much to improve the position, though the bonding present in molybdenum(II) chloride derivatives has never been seriously discussed and many simple physical measurements remain to be done and correlated with the proposed structures A re-investigation of these compounds is now particularly important as they appear to possess a stereochemistry quite different from that indicated for d^4 metal complexes by ligand field theory Therefore molybdenum(II) chloride and its derivatives are being re-examined and it is now possible to summarize some new experimental results and propose a bonding scheme for these compounds This bonding scheme is able to explain why only certain types of ligands form molybdenum(II) chloride complexes

The crystalline compounds studied by Brosset were formulated on the basis of his structure determinations as $[(Mo_6Cl_8)\{(OH)_4(H_2O)_2\}]\ 12H_2O$[1] and $[(Mo_6Cl_8)\{Cl_4(H_2O)_2\}]\ 6H_2O$[2] The structure of the $(Mo_6Cl_8)^{4+}$ group, fully named octa-μ_3-chlorohexamolybdenum(II) and henceforth referred to as the chloromolybdenum(II) group, is given in Fig 1 It is convenient for most purposes to regard the group

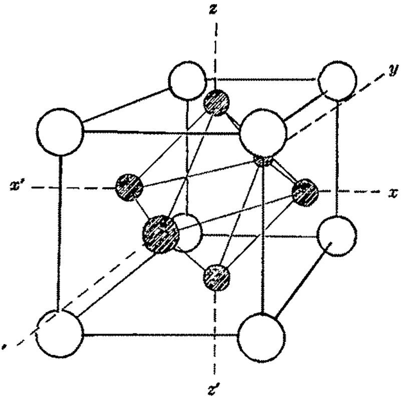

Fig 1 The chloromolybdenum(II) group White circles, Cl, shaded circles, Mo

as a regular face-centred cube and it is presented in this manner in the figure Though the octahedron described by the molybdenum atoms is almost regular, the cube described by the chlorine atoms is somewhat distorted and it is possible that the deviation from strict equivalence of these chlorine atoms may be of some chemical significance Brosset has emphasized that six groups, given in braces in the formulæ above, appear closely associated with the chloromolybdenum(II) unit Fig 1 shows that each molybdenum atom is surrounded by a square planar configuration of chlorine atoms, and can accept one ligand normal to the cube face to achieve co-ordinative saturation The effective co-ordination number of each molybdenum atom, taking into account the four molybdenum close neighbours, would be nine, and it is therefore improbable that more than one ligand could donate to each molybdenum atom Thus six ligands may be accepted by the chloromolybdenum(II) group along the axes *xx'*, *yy'* and *zz'* Whereas the identity of the central ($\mathrm{Mo}_6\mathrm{Cl}_8$) unit is seldom affected, the six ligands are freely variable There is possible a novel range of octahedral complexes, their general character being of the type familiar to the inorganic chemist, but possessing a polyatomic nucleus

The chloromolybdenum(II) group is stable over a wide range of conditions In the form $(\mathrm{Mo}_6\mathrm{Cl}_8)\mathrm{Cl}_4$, that is, MoCl_2, it is not affected by boiling aqua regia or concentrated sulphuric acid heated to fuming, other than the displacement of the chlorine ligands It is stable to more than 800° C *in vacuo*, with probable disproportionation to metal and higher halides above this temperature It is not oxidized by air below 300° C, but above this temperature a dark product is formed However, it is much more sensitive to aqueous alkali giving molybdenum(V) hydroxide and hydrogen At room temperature and *p*H 12, a chloromolybdenum(II) solution shows some signs of decomposition in about 10 hr, though at higher *p*H and temperature decomposition can be complete in a few minutes It is noteworthy that the reagents most disruptive for the ($\mathrm{Mo}_6\mathrm{Cl}_8$) group are the strong electronegative complexing agents, namely, OH^-, F^- and NCS^-, though attack by these is rapid only at high temperatures It is therefore possible that the decomposition of the chloromolybdenum(II) group under these conditions proceeds by the formation of an unstable substituted chloromolybdenum(II) nucleus As this group retains its identity under most conditions, it is proposed to designate it as '*M*' in formulæ

The present work strongly supports the view that the chloromolybdenum(II) group invariably possesses six groups bound to it The following are typical examples of the new compounds isolated $[M\mathrm{Cl}_4(\mathrm{C}_5\mathrm{H}_5\mathrm{N})_2]$, $[M\mathrm{Cl}_4((\mathrm{C}_2\mathrm{H}_5)_3\mathrm{N})_2]$, and $(\mathrm{H}_3\mathrm{O})_2[M\mathrm{I}_6]$ $6\mathrm{H}_2\mathrm{O}$ Compounds with compositions corresponding to the following have also been reported[4] $[M\mathrm{Cl}_4(\mathrm{H}_2\mathrm{O})_2]$, $[M\mathrm{Cl}_4(\mathrm{C}_2\mathrm{H}_5\mathrm{OH})_2]$, $\mathrm{K}_2[M\mathrm{Cl}_6]\,6\mathrm{H}_2\mathrm{O}$, $[M\mathrm{Br}_4(\mathrm{H}_2\mathrm{O})_2]$, and $(\mathrm{H}_3\mathrm{O})_2[M\mathrm{Br}_6]\,6\mathrm{H}_2\mathrm{O}$ The parent acid of the hexachloro-chloromolybdenum(II) series has been known in the crystalline form as $(\mathrm{H}_3\mathrm{O})_2[M\mathrm{Cl}_6]\,6\mathrm{H}_2\mathrm{O}$ for some time[5] It is the most soluble hexachloro-complex, the salts of this acid being sparingly soluble or completely insoluble Typical salts include those of the alkali metals, ammonium and pyridinium[4] The insoluble salts derived from large organic cations, for example, tetraethylammonium and triphenylphosphonium, have been prepared in the present work The salts of the hexabromo- and hexaiodo-acids are less well known but are undoubtedly similar to those of the hexachloro-acid The hexahalogeno-acids and their salts are rapidly hydrolysed in aqueous solution and an excess of hydrohalogenic acid must be maintained for stable solution Solvolysis of these compounds is not observed in ethanol and solubilities often prove to be much higher in this solvent

In addition to $M\mathrm{Cl}_4$, it has now been possible to prepare $M\mathrm{Br}_4$, $M\mathrm{I}_4$ and $M(\mathrm{OH})_4$ by heating the appropriate hexahalogeno-acid or hydrated chloromolybdenum(II) hydroxide *in vacuo* at 250° C As there appears to be only four ligands per chloromolybdenum(II) nucleus it is reasonable to suppose that these compounds are polymeric using some ligands for bridging between chloromolybdenum(II) groups and thus satisfying the proposed octohedral requirements However, it is interesting to note that Brosset has shown the hydrates of $M\mathrm{Cl}_4$ and $M(\mathrm{OH})_4$ to consist of discrete octahedral complexes In passing, it may be mentioned that the four simple chloromolybdenum(II) compounds referred to above are found to be hygroscopic and undergo a lightening of colour on gaining water The materials may be obtained anhydrous again by reheating *in vacuo*

Complexes of the type $[M(\mathrm{OH})_6]^{2-}$, $[M(\mathrm{H}_2\mathrm{O})_6]^{4+}$ and $[M(\mathrm{NCS})_6]^{2-}$ are of interest but attempts to prepare solid compounds of the first two have failed so far Such compounds undoubtedly exist in solution as chloromolybdenum(II) hydroxide is soluble in 2 *N* acid and 0 01 *N* alkali It has been possible to confirm the existence of $[M(\mathrm{OH})_6]^{2-}$ in solution by the *p*H titration involving the precipitation of the hydroxide by standard acid from a standard alkaline solution Fig 2 shows a typical titration curve in which two equivalents of nitric acid precipitate one of $M(\mathrm{OH})_4$ Thus chloromolybdenum(II) hydroxide dissolves in alkali to give the complex $[M(\mathrm{OH})_6]^{2-}$ The addition of $[M\mathrm{Cl}_6]^{2-}$ to a concentrated potassium thiocyanate solution gives a crystalline precipitate possessing a chloride and thiocyanate content reasonable for $K_2[M(\mathrm{NCS})_6]\,6\mathrm{H}_2\mathrm{O}$ However, the compound is soluble in water, precipitating only in excess thiocyanate, and attempts to free the precipitate from the contaminating potassium thiocyanate have not proved successful so far

The ideas expressed above might be criticized on the grounds that the chloromolybdenum(II) nucleus or its proposed co-ordination complexes are, in fact, ionic assemblages rather than covalent compounds Though this is inconsistent with the chemical data already given, there is good evidence to settle this

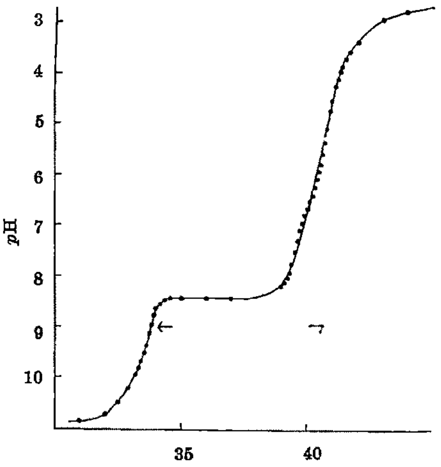

Fig 2 The precipitation of 3 29 × 10^{-4} moles of $M(OH)_4nH_2O$ occurred in the region between the arrows

point Brosset has established that the hexachloro-acid exists as $[MCl_6]^{2-}$ in ethanolic solution by an X-ray diffraction technique[3] Molecular weight determination of molybdenum(II) chloride in boiling ethanol has been found to give just over half the required value for MCl_4 [6] Under these conditions, it is very probable that some alcoholysis occurred, but ionization to a degree suggested by $M^{4+}(Cl^-)_4$ as the true constitution of molybdenum(II) chloride is ruled out Thus, in a moderately strong solvating solvent, like ethanol, the M—Cl bonds retain their identity A number of chlorine-36 exchange studies to determine the lability of the chlorine atoms in the $[MCl_6]^{2-}$ ion have been carried out in the present investigation The first experiments were carried out in 5 65 N hydrochloric acid to avoid hydrolysis The hexachloro-acid was allowed to exchange with labelled hydrochloric acid, and the complex separated from solution either by freezing out at 0° C as the crystalline acid or precipitated as the triphenylphosphonium salt. The first separation method gave a very pure material, the second gave a rapid quantitative precipitation It was found that the exchange fraction corresponded closely to the exchange of only six out of the fourteen chlorine atoms in $[MCl_6]^{2-}$ for exchange times of 2–800 min at 25° C For times of exchange less than 2 min , less than six out of fourteen chlorine atoms exchanged, but the data are inaccurate It is reasonable to conclude that all fourteen chlorine atoms in $[MCl_6]^{2-}$ are covalently bound, but the ligand chlorine atoms are much more labile than the nuclear chlorine atoms in 5 65 N hydrochloric acid The inertness of the eight nuclear chlorine atoms is striking, for on refluxing the hexachloro-acid for 1½ hr in hydrochloric acid, only six out of fourteen had exchanged

At this point it is logical to consider whether chloromolybdenum(II) should have a chemistry analogous to some mononuclear cation, or whether the resemblance is superficial It is true that if the molybdenum(II) atoms were held together by a cage of shared chlorine atoms, it may well be that the compounds resembling octahedral complexes could be isolated However, these would have the properties expected of divalent molybdenum, frequently displaying paramagnetism, ligand field spectra and a strong tendency to oxidation This is in striking contrast to what is observed, for chloromolybdenum(II) complexes are very stable to oxidation and are all diamagnetic Solution absorption spectra give no indication of ligand field spectra, only one or more bands at about 300–350 mμ, $\varepsilon \sim 3 \times 10^3$, which account for the deep yellow colour of the compounds It is possible, however, that these charge transfer bands may be superimposed on some very weak d–d transition bands Fig 3 gives the absorption curves assigned to the species $[MCl_6]^{2-}$ and $[MBr_6]^{2-}$ in 5 N hydrochloric and hydrobromic acid, respectively, and $[M(OH)_6]^{2-}$ in 0 01 N alkali It is important to bear in mind that the properties suggested above for molybdenum(II) are hypothetical as no paramagnetic molybdenum(II) compounds are known and complexes of the type $[Mo(II)X_6]$, from which $[MX_6]$ might be considered to be derived, do not exist Furthermore, mononuclear molybdenum(II) compounds are very rare (see below) If molybdenum(II) is spin-paired in chloromolybdenum(II), accounting for its diamagnetism, combination of this group with carbon monoxide-like ligands would be expected, and again this is not found There is no evidence that MCl_4 is affected by carbon monoxide at 40 atm. and 110° C or by triphenylphosphine at 200° C It is significant that among the few mononuclear molybdenum(II) complexes known, $[Mo(II)(diarsine)(CO)_3I_2]$, $[Mo(II)(diarsine)_2(CO)_2I^+]I^-$ and similar compounds have recently been prepared by Nyholm and co-workers by halogenation of tetracarbonyl-(*o*-phenylene-*bis*(dimethylarsine))molybdenum(0)[7] These compounds are diamagnetic, contain carbon monoxide-like ligands and possess ligand field spectra and co-ordination number seven Therefore, the chloromolybdenum(II) group behaves quite differently from that reasonably expected on molybdenum(II), and moreover, differently from any transition metal other than one with a d^0 configuration It is then justifiable to regard the chloromolybdenum(II) group as a particular and distinct chemical entity and not as an assemblage of atoms in a rather special geometry

The non-appearance of typical transition metal properties is not difficult to explain The intermolyb-

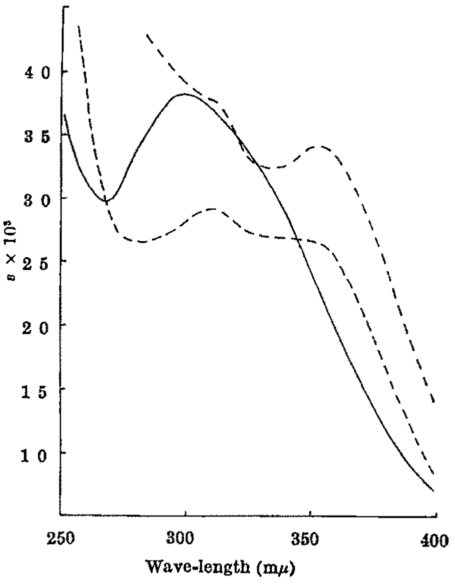

Fig. 3 — —, $[MBr_6]^{2-}$, ——, $[M(OH)_6]^{2-}$, - - -, $[MCl_6]^{2-}$

denum distance is 2 63 A. to be compared with 2 73 A for molybdenum metal, and therefore Mo–Mo bonds must exist along all sides of the Mo_6 octahedron The highly symmetrical arrangement of the Mo_6 group allows convenient consideration of the intermolybdenum bonds as delocalized and best represented by molecular orbitals For the purposes of discussion the $[MCl_6]^{2-}$ complex will be considered Each molybdenum atom is surrounded by a tetragonal pyramid of chlorine atoms, bonded probably by $d_{(x^2-y^2)}sp^3$ hybrid orbitals Of the remaining four d-orbitals, the d_{xz} and d_{yz} possess lobes directed exactly along the intermolybdenum axes and it is possible for each of four co-planar molybdenum atoms to combine one of these orbitals to give a molecular orbital system There are three such sets of co-planar atoms, each forming such orbitals The contribution of two d-electrons per molybdenum atom to forming such intermetallic bonds gives molybdenum a valency higher than the oxidation number two The disposition of the two remaining electrons in the d_{xy} and d_{z^2} orbitals must be consistent with the observed properties of chloromolybdenum(II) compounds Pairing the electrons in one of the two remaining orbitals may account for diamagnetism, but possibly not the other properties Furthermore, the proximity of the molybdenum atoms to each other also suggests that there would be some repulsive interaction between non-bonding pairs in either the d_{xy} or d_{z^2} orbitals. It is concluded that the two remaining electrons occupy the orbitals singly, and that these contribute a little more to the intermolybdenum binding by coupling their spins

Therefore, chloromolybdenum(II) can best be regarded as a compound of molybdenum(VI) employing all nine orbitals This is quite consistent with crystallographic evidence, for Brosset reports that each molybdenum atom possesses nine neighbours all closer than 2 7 A The hexavalency of molybdenum explains the absence of observable d–d transitions in spectra and the inability to form complexes with π-bonding ligands The apparent conflict of the stereochemistry of chloromolybdenum(II) with ligand field theory is removed Though the theory suggests a number of favoured arrangements for d^4 complexes, it seems unable to account for the arrangement in chloromolybdenum(II) This difficulty disappears when the compounds are recognized as d^0 complexes

In conclusion, the following points are re-emphasized Molybdenum(II) chloride complexes contain the chloromolybdenum(II) group, $(Mo_6Cl_8)^{4+}$, which functions as a nucleus for octahedral complexes of the form $[MX_6]$ The chloromolybdenum(II) group exhibits intermetallic bonding, and though the oxidation number of molybdenum is two, the valency is effectively six Consistent with the d^0 character of the molybdenum is co-ordination number nine Furthermore, this d^0 character explains the diamagnetism, absence of both ligand field spectra and complexes with π-bonding ligands of chloromolybdenum(II) compounds

I wish to acknowledge the award by the University of London of an I C I. Research Fellowship during the tenure of which this investigation was conducted, and also to express my indebtedness to Prof R S. Nyholm and Dr. J Lewis for their suggestion and support of the research

MASSIVE INCORPORATION OF 5-FLUOROURACIL INTO A BACTERIAL RIBONUCLEIC ACID

By Dr. JACK HOROWITZ and Prof. ERWIN CHARGAFF
Cell Chemistry Laboratory, Department of Biochemistry, College of Physicians and Surgeons,
Columbia University, New York

IN the course of studies on the correlation of the mechanisms controlling the production of cellular high-polymers, we have investigated the effects of 5-fluorouracil on the synthesis of protein and nucleic acid in several strains of *Escherichia coli* We have reported elsewhere (ref 1, and unpublished work by the same authors) on the ability of the fluoro compound to substitute, in part, for uracil in a mutant requiring this pyrimidine In the absence of uracil, the addition of 5-fluorouracil resulted in the doubling of the protein content, a slight increase in ribonucleic acid, but none in deoxyribonucleic acid, took place. In *E. coli*, strain *B*, as well as in the uracil auxotroph supplemented with uracil, the fluoro pyrimidine inhibited the synthesis of deoxyribonucleic acid completely, but permitted the formation of both protein and ribonucleic acid

The formation, in the presence of 5-fluorouracil, of several constitutive or inducible enzymes was also examined The activity of two of the enzymes, catalase and succinate dehydrogenase, increased , the induction of β-galactosidase by lactose was, on the other hand, almost entirely blocked in the presence of 5-fluorouracil The fluoropyrimidine prevented, moreover, any further rise of the β-galactosidase activity in cells that had previously been treated with the inducer or in a strain of *E coli* in which this enzyme is constitutive Other observations, soon to be published in collaboration with Drs. F Goodman and J J Saukkonen, showed that 5-fluorouracil prevented the multiplication of *T2r* bacteriophage and the intracellular synthesis of the phage nucleic acid in *E coli*, strain *B*, whereas it had less influence on the growth of *T*3

These findings, as well as the recent reports on the incorporation of 5-fluorouracil into the ribonucleic acids of animal tissues[2,3] and of tobacco mosaic virus[4], made it of interest to ascertain whether also in *E coli* the biological effects of the fluoro compound are accompanied, or caused, by its

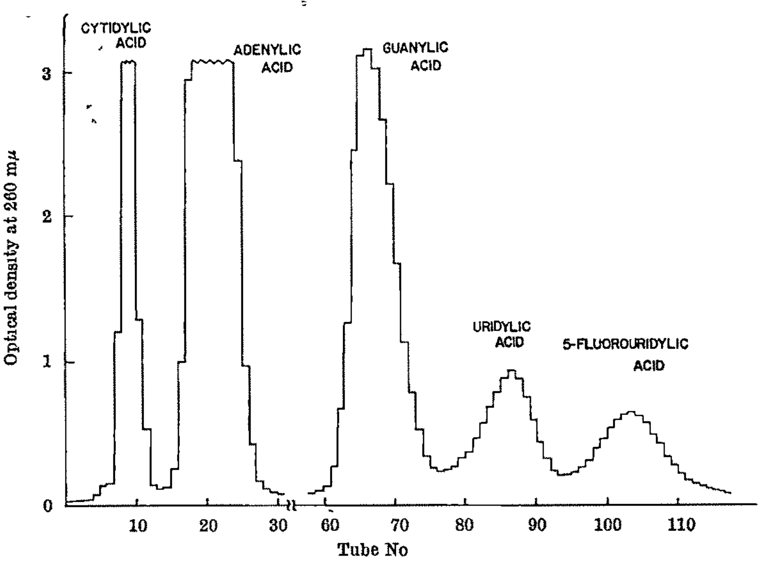

Fig 1 Elution diagram of the hydrolysate of the ribonucleic acid of *E coli*, strain *B*, formed in the presence of 5-fluorouracil 'Dowex-2-formate' (8 times), 200–400 mesh, 23 cm × 0 9 cm diameter, gradient elution (mixing chamber 500 ml water, reservoir 2 5 *N* formic acid), 7 ml fractions

introduction into the ribonucleic acid The results presented here show that a considerable amount of this uracil analogue does indeed find its way into the ribonucleic acid of the organism, where it may replace nearly one-half of the normally present uracil

To cultures (37°, glucose-salts medium, early logarithmic phase) of *E coli*, strain *B*, or of the uracil-deficient mutant 63–86, supplemented with uracil (20 μgm /ml), 5-fluorouracil (50 μgm /ml) was added and the cell suspensions were kept at 37° for varying periods If the action of the inhibitor on the uracil auxotroph was to be tested in the absence of uracil, the cells were harvested and starved before the addition of the fluoropyrimidine[1] At the conclusion of the treatment, the organisms were collected and prepared for analysis (removal of mononucleotides, lipids, etc) by procedures described previously[5]. The hydrolysis of the ribonucleic acid was carried out with 0 3 *N* alkali (30°, 18 hr) with the use of either sodium hydroxide, in which case the hydrolysate was acidified with hydrochloric acid in order to precipitate protein and deoxyribonucleic acid, or of potassium hydroxide , in the latter case perchloric acid was employed, care being taken to avoid losses through the co-precipitation of nucleotides during the removal of potassium perchlorate in the cold The ribonucleotide composition was determined by electrophoresis on filter paper or by ion-exchange chromatography

A typical elution pattern (Fig 1) shows five components, with the new nucleotide leaving the column after uridylic acid, as expected for a mixture of the 2′- and 3′-phosphates of 5-fluorouridine[3] The combined eluates of this component collected in several runs were again subjected to chromatography , the experimental conditions were as in Fig 1 except that *N* ammonium formate was used for gradient elution A single sharp peak was observed and the nucleotide identified as 5-fluorouridylic acid The hydrolysis of the compound with 72 per cent perchloric acid (1 hr , 100°) liberated 5-fluorouracil, which was identified by chromatography and spectrophotometry , the molar ratio of 5-fluorouracil to phosphorus was found to be 1 1 17 The treatment of the nucleotide with prostate phosphatase resulted in the liberation of 5-fluorouridine, which was identified by the comparison of its spectral and electrophoretic (0 1 *M* borate buffer of *p*H 9 2 [6]) properties with those of the authentic nucleoside The ratio of 5-fluorouridine to phosphate released by the enzymic hydrolysis was 1 1 1 That the nucleotide consisted of a mixture of the 2′- and 3′-phosphates of 5-fluorouridine and had, therefore, formed part of a polynucleotide, was shown by its behaviour towards 3′- and 5′-nucleotidases It was not attacked by the 5′-nucleotidase of Russell's viper venom, whereas 3′-nucleotidase[7] hydrolysed about 60 per cent of the nucleotide to fluorouridine within 20 hr 5-Fluorouridylic acid has its absorption maximum at 268 mμ in 0 01 *N* hydrochloric acid with a molar extinction coefficient of 9,400 , the absorbance ratios in the same solvent are A_{250}/A_{260}, 0 64 , A_{280}/A_{260}, 0 82 , A_{290}/A_{260}, 0 32

The nucleotide composition of the ribonucleic acid synthesized, both in the presence and the absence of 5-fluorouracil, by the two *E coli* strains under investigation is shown in Table 1 It will be seen that one-quarter to nearly one-half of the nucleic acid uracil can be replaced by the fluoropyrimidine This takes place without an essential disturbance of the equality of the molar sums of 6-amino and of 6-keto nucleotides[10] The large quantities of 5-fluorouracil built into the ribonucleic acid of strain *B* offer a convenient method for the preparation of the 2′-, 3′-, and 5′-phosphates of 5-fluorouridine It is noteworthy that 5-fluorouridylic acid was also found in the ribonucleic acid of the uracil-requiring mutant incubated with the fluoropyrimidine in the absence of uracil, although the amount of nucleic acid synthesized under these conditions is slight (ref 1, and unpublished work by the same authors) Owing to the relatively small number of analyses it is not yet clear what importance should be attached to the fluctuations in nucleotide proportions recorded in Table 1 , nor is it yet known whether 5-fluorouracil is incorporated preferentially into any particular fraction of the total ribonucleic acid or into certain positions on the polymer chain

In contrast to the known metabolic fate of uracil, we have found no indication that 5-fluorouracil gives rise also to a 5-fluorocytidylic acid component of the nucleic acid Preliminary evidence would, in fact, seem to speak against the presence of the latter fluoro nucleotide, at least in amounts comparable to those of 5-fluorouridylic acid Neither elution peak nor chromatographic zone corresponding to 5-fluorocytidylic acid was seen , the spectra of the separated nucleotides showed no evidence of such a contaminant Moreover, orienting experiments on the uptake of uracil-2-^{14}C by the ribonucleic acid of the uracil auxotroph exclude the occurrence of appreciable quantities of 5-fluorocytidylic acid As shown in Table 2, 5-fluorouracil depresses the incorporation of

Table 1 NUCLEOTIDE COMPOSITION OF RIBONUCLEIC ACID OF *E coli* STRAINS

No	Specimen*	Analytical procedure†	Moles per 100 moles nucleotide in ribonucleic acid				
			Adenylic acid	Guanylic acid	Cytidylic acid	Uridylic acid	5-Fluorouridylic acid
1	Strain *B*, normal	I	26 3	29 6	25 1	19 0	—
2	Strain *B*, treated with 5-fluorouracil, 21 hr	II	23 1	30 4	25 2	11 4	9 8
3	Uracil auxotroph 63–86, normal	III	23 7	32 6	23 0	20 8	—
4	Uracil auxotroph 63–86, treated with 5-fluorouracil, in the presence of uracil, 3 hr	III	24 6	30 4	24 3	15 9	4 8
5	Uracil auxotroph 63–86, treated with 5-fluorouracil, in the absence of uracil, 16 hr	II	23 3	32 7	22 5	17 4	4 0

* The figures for No 1, averages of many determinations, are taken from a previous publication (ref 8), those for No 3 are based on several hydrolysis experiments Specimens No 2, 4 and 5 were single preparations Preparations of strain 63–86 treated with 5-fluorouracil, in the presence of uracil, for 1 and 2 hr, gave results very similar to those reported for specimen No 4

† The following procedures were employed (I) chromatography on filter paper in the isobutyrate solvent (ref 8), (II) separation of nucleotides liberated by sodium hydroxide on 'Dowex-2-formate' columns by gradient elution with formic acid (ref 3), (III) separation of nucleotides liberated by potassium hydroxide through electrophoresis on filter paper in 0 02 *M* citrate buffer of *p*H 3 5 (ref 9) In the last-mentioned system uridylic and 5-fluorouridylic acids migrate together The fluoronucleotide was, therefore, determined separately by electrophoresis in 0 1 *M* borate buffer of *p*H 9 15, in which it migrates as the fastest component (ref 4), and the estimates of uridylic acid were suitably corrected

uracil into the uridylic acid, but not its utilization for the cytidylic acid, of the ribonucleic acid of the mutant It may also be mentioned that we have encountered no indication of the entrance of 5-fluorouracil into the deoxyribonucleic acid of *E coli*

Table 2 EFFECT OF 5-FLUOROURACIL ON INCORPORATION OF URACIL-2-^{14}C INTO *E coli* RIBONUCLEIC ACID

Exponentially growing cells of the *E coli* mutant 63–86 were washed and starved of uracil (ref 1) After the addition of uracil-2-^{14}C (20 μgm /ml, specific activity 25,000 c p m /μmole) the preparation was divided into two equal parts one of which received 5-fluorouracil (50 μgm /ml) During the subsequent incubation at 37° C for 3 hr, equal amounts of ribonucleic acid were formed in both preparations The radioactivity found in the purine nucleotides and in 5-fluorouridylic acid amounted to less than 5 per cent of that incorporated into the pyrimidine nucleotides The results are reported per ml of cell suspension

Specimen	Uracil-2-^{14}C incorporated (μm moles per ml)		Incorporation ratio, uridylic acid to cytidylic acid
	Uridylic acid	Cytidylic acid	
Normal	25 1	29 5	0 85
Treated with 5-fluorouracil	14 3	30 0	0 48

We are indebted to Dr J A Aeschlimann, Hoffmann-La Roche, Inc, Nutley, N J, for specimens of the fluoro compounds used in these studies. The uracil-requiring mutant, originally isolated by Prof B D Davis, of Harvard University, was given us by Dr E Borek We are grateful to Dr J J Saukkonen for helpful discussions and to Mr R L Cooper for technical assistance The work was supported by grants from the United States Public Health Service and the National Science Foundation

MEASUREMENTS OF TEMPORAL ADAPTATION TO SPATIAL DETAIL VISION

By A. J. SEYLER and Z L. BUDRIKIS

Research Laboratories, Postmaster-General's Department, Melbourne

THERE is neurophysiological and psychological evidence[1-3] that temporal as well as spatial adaptation processes are involved in visual perception From this we argued that after the presentation of a new visual pattern a certain time may be required for a viewer to recognize spatial detail in this new pattern

A quantitative measure of the perceptual time delay versus the size of detail would be a significant design parameter for a variety of control and communication systems involving the human sense of vision. Tachistoscopic visual recognition tests and reaction time measurements have been reported[4,5], but we think that these have a different significance, because the object, and thus the design, of the experiments are different.

The idea behind our experiments was that, if the viewer requires a definite adaptation time to perceive spatial detail in a newly presented visual scene, it should be possible to measure this effect by presenting the new scene in such a way that the detail size is decreased progressively in time after the instant of presentation In other words, the new scene is 'blurry' when it is presented to the viewing subject and is made increasingly 'sharper' as function of time If this temporal increase in objective sharpness occurs faster than the subjective adaptation to the perception of detail, the viewer will not notice the effect If, however, the temporal adaptation process of the viewing subject proceeds faster than the objective increase in sharpness, it will be noticed by the subject that the scene had been blurred initially It will be recognized that this approach contains certain elements of transient response testing of electrical systems where the response to a finite transition (in time and amplitude) is given by the convolution of excitation and transfer function Hence, for our tests, we argued that the finite temporal increase in sharpness will not be noticed, when the perceptual time response to it is not 'noticeably' slower than what it would have been to a scene which was sharp from the instant of its presentation (response to an ideal stimulus).

Because the 'sharpness' of a picture can be conveniently varied (along the horizontal dimension) by varying the band-width of a television picture signal using a variable low-pass filter, television-type presentation was chosen This also facilitated rapid change-over from one scene to another by electronic means The test scenes were stationary (slides) while between presentations of these was displayed an 'interlude' of a normal television programme without sound received from local stations This, we found, prevented staring at the display area, provided relaxed viewing conditions with no specific bias towards any one fixation point and introduced a close similarity to actual viewing in everyday situations

The experimental conditions were as follows Television pictures in accordance with the C C I R Standard (625/50/25) having a maximum signal band-width of 5 Mc /s. were displayed on a studio monitor of 9 in × 12 in. picture dimensions The monitor was surrounded by a flat grey surface, 48 in × 68 in Indirect ambient lighting was used in the test area The brightness of the surround was 0 2 foot-lambert, picture peak white 4 foot-lambert and picture black 0 1 foot-lambert (measured with *SEI*-Photometer) Two different viewing distances were used, one at four times, the other at eight times, picture height Correspondingly, the maximum picture dimension (width) had a subtended angle of 19° and 9° 30′ for the two distances and minimum detail size for any signal band-width of B Mc /s is given by 11 4/B and 5 7/B minutes of arc respectively

By means of a voltage-controlled continuously variable low-pass filter[6] the signal band-width was varied from a minimum B_m Mc /s at the time of scene change-over, $t = 0$, to the system band-width of $B_s = 5$ Mc /s at $t = T$ in accordance with the following time function

$$B(t) = B_m \exp\left(\frac{t}{T} \log \frac{B_s}{B_m}\right) \text{ Mc /s}, \quad 0 < t < T$$

Thus the minimum detail size in minutes of arc subtended angle varied for the two viewing distances as

$$S(t)_4 = \frac{11\ 4}{B(t)} \text{ and } S(t)_8 = \frac{5\ 7}{B(t)}$$

The minimum band-width B_m (degree of blurriness) and the recovery time T as well as the test slide were preset by the experimenter without the subject knowing the conditions After being prompted by the experimenter the subject pressed a control button by which the interlude scene was replaced by the test scene The equipment was controlled so that change-over took place during the suppression interval (of approximately 1 5 msec) between television frames following the pressing of the button This instant being time $t = 0$ was also the beginning of the recovery of the filter from the preset minimum to full system band-width, which caused the increasing of the objective picture sharpness over the interval $0 < t < T$ Shortly afterwards, the subject announced by 'Yes' or 'No' whether a blurring of the picture was 'seen' or not The test slide display was then changed back to the interlude by the experimenter before the next experimental condition was established An average of not more than 150 decisions were made by each subject during a single session in order to prevent tiring The sequence of the three experimental parameters was selected from a table of random numbers

In tests of this nature it is desirable to have approximately equal frequencies for 'Yes' and 'No' We therefore carried out exploratory tests at a viewing distance of four times picture height by which we intended to find values for B_m for which the decisions went from 100 per cent 'No' to 100 per cent 'Yes' when T was varied For B_m ranging from 0 28 to 4 Mc /s and T from 20 to 2,600 msec , full transitions from 100 per cent 'No' to 100 per cent 'Yes' could only be obtained for B_m less than 1 Mc /s At this particular setting the percentage 'No' never fell below 60 per cent and seemed to vary in an unsystematic way for recovery times exceeding 1 sec We therefore concentrated on the two values of 0 28 and 0 5 Mc /s for B_m, corresponding to 40 6 and 22 8 minutes of arc for the maximum detail size at four times picture height and 20 3 and 11 4 minutes of arc at eight times picture height viewing distance The minimum detail size for the two distances and $t > T$ was 2 28 and 1 14 minutes of arc For each setting of B_m eight different recovery times were used, being $50 < T < 2{,}600$ msec and $40 < T < 2{,}080$ msec for $B_m = 0\ 28$ and $B_m = 0\ 5$ Mc /s respectively

Three different test slides were displayed One of these depicted a group of three children, the second an aerial view of a city and the third a stone hut, all three contained fine detail and sharp contours of good contrast but different distribution over the picture area Since the experiment was not concerned with a semantic recognition, the pictorial content of the slides was of less significance than the availability of detail to which the subject's perception would adapt itself

Four male subjects belonging to the staff of the Laboratories were tested They were all familiar with the experiment and the appearance of the reduced detail presentation. Therefore, they may be classed as skilled and critical observers

The 'percent not seen' ('No') for each experimental condition were computed taking the decisions of all subjects on all test slides together The resulting

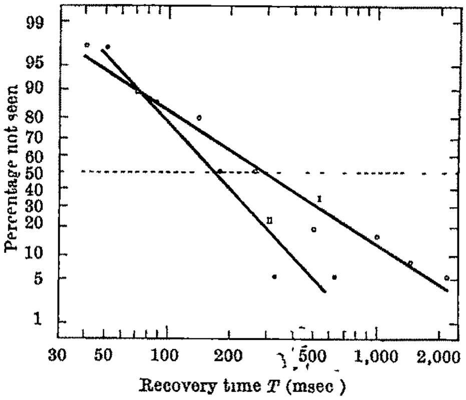

Fig 1 Percentage not seen versus recovery time Viewing distance, four times picture height I, (○ – ○) $B_m = 0\ 5$ Mc /s, $S_{\max} = 22\ 8$ min of arc, II, (● – ●), $B_m = 0\ 28$Mc /s , $S_{\max} = 40\ 6$ min of arc

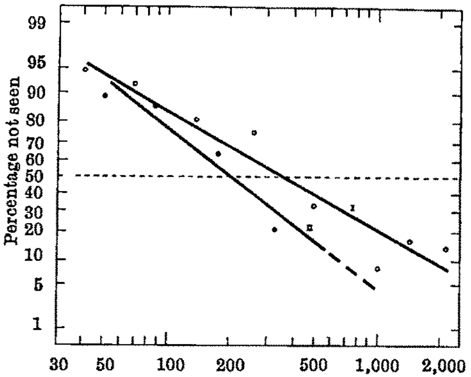

Fig 2 Percentage not seen versus recovery time Viewing distance, eight times picture height I, (○ – ○) B_m = 0 5 Mc /s , S_{max} = 11 4 min of arc , II, (● – ●) B_m = 0 28 Mc /s , S_{mx} = 20 3 min of arc

experimental points were fitted to a normal distribution versus the logarithm of recovery time (T) as shown in Figs 1 and 2, using the method of least squares Each point represents 36 decisions The permissible recovery times for which the initial lack of sharpness in detail was not seen in 50 per cent of the presentations are listed with the respective experimental conditions in Table 1

Although within the same viewing distance the permissible recovery time increases approximately in the same ratio as the initial detail size decreases, for the doubling of the viewing distance (that is, halving of detail size for the same B_m) the recovery time increases only by a factor 1 25

From what is known about human sensual phenomena we cannot expect linear behaviour over any extended range of inputs and stimulus conditions Hence we consider it unjustified to attempt an extrapolation from the restricted data at our disposal at this time However, the main conclusions which we may draw from the results of the experiment are that a certain time is required after the presentation of a new and remaining visual display before the perception threshold for fine detail is reached, and that due to this effect it is possible to expand the time interval within which detail in changing complex visual displays is offered to the viewer without noticeably interfering with the normal perception process

Table 1

Viewing distance (picture height)	4 times		8 times	
Minimum detail (min of arc)	2 28		1 14	
Maximum detail (min of arc)	40 6	22 8	20 3	11 4
Recovery time (msec) for 50 per cent 'No'	160	290	200	360

It must be left to further extended experiments to attempt a determination of the functional relationships between the relevant parameters

EFFECT OF OXYGEN TENSION ON HÆM AND PORPHYRIN BIOSYNTHESIS

By J. E. FALK, R. J PORRA and ANN BROWN
Division of Plant Industry, Commonwealth Scientific and Industrial Research Organization, Canberra
AND
F. MOSS and HELEN E. LARMINIE
Biology Department, University of New South Wales, Sydney

THE adaptive synthesis of cytochromes in aerobic and anaerobic conditions of culture is well known[1]. It has been shown by one of us[2] that as the oxygen tension in the culture medium is increased, the synthesis of cytochrome a_2 by *Aerobacter aerogenes* increases to a maximum, and then decreases when still higher oxygen tensions are applied The maximum was reached when the oxygen concentration in the medium was of the low order of 0 1 *M* It was suggested that a self-regulatory mechanism may operate, the formation of cytochrome a_2 being controlled in accordance with the respiratory requirements imposed by [illegible] prevailing oxygen tension

It occurred to [illegible] that prosthetic group synthesis might be affected by the oxygen tension The prosthetic group of cytochrome a_2 is an iron-chlorin[3], and nothing is yet known about the biosynthesis of this cytochrome or its prosthetic group It has now been found, however, that the biosynthesis of protoporphyrin and hæm, in chicken erythrocyte preparations *in vitro*, appears to be regulated by oxygen tension

Whole blood (25 ml) from normal chickens was shaken with glycine (final concentration 0 056 *M*) and 1 mgm each of heparin, penicillin and streptomycin, at 38° C The gas mixtures all contained 5 per cent carbon dioxide and the relevant concentration of oxygen , nitrogen was used as diluent The mixtures were made in aspirators, and by displacement with water were bubbled through the incubation mixture at the rate of 2 1 /hr The conical incubation flasks were closed with Bunsen valves, and frothing was controlled by a few drops of octanol When washed cells were used, 25 ml of blood was centrifuged and the serum and the 'buffy coat' removed The erythrocytes were washed three times with isotonic sodium chloride and resuspended in isotonic sodium chloride to a final volume of 25 ml Substrates and antibiotics were then added, and incubations carried out, as described for whole blood Porphyrin and hæm synthesis were determined as described by Dresel and Falk[4]

As shown in Fig 1, the synthesis of copro- and proto-porphyrins and hæm in this system is regulated by oxygen tension The synthesis of protoporphyrin and hæm is related linearly to time under these conditions (cf Fig 3, and Dresel and Falk[4])

It is not possible, without further experiments, to say whether or not the optimum oxygen tension for the synthesis of hæm is the same as that for protoporphyrin The situation is complicated by the effects of oxygen upon the incorporation of iron into protoporphyrin The tissue-catalysed combination of ferrous iron with protoporphyrin is inhibited by oxygen[6], and the liberation of iron from storage in liver ferritin is promoted by low oxygen tensions[7] Such factors may contribute to the very great inhibition of hæm synthesis at the highest oxygen tensions (Fig 1)

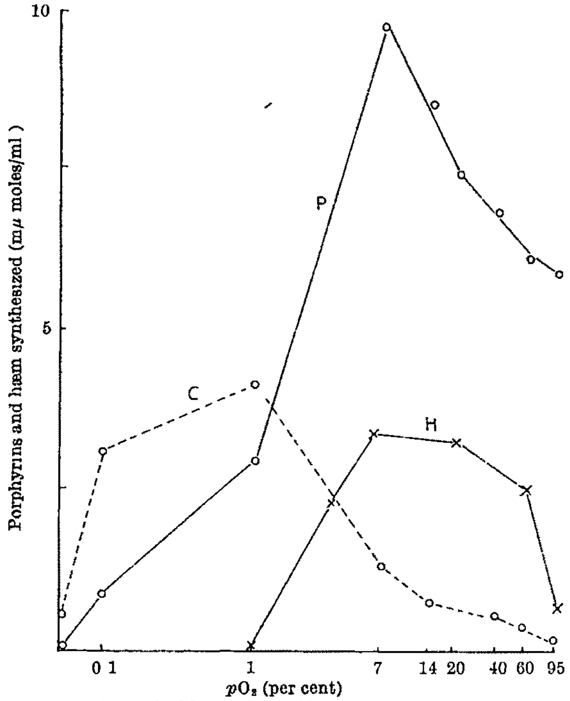

Fig 1 The control by oxygen of hæm and porphyrin synthesis from glycine in whole chicken blood Whole blood (25 ml) was incubated for 8 hr , as described in the text *P*, protoporphyrin , *C*, coproporphyrin , *H*, hæm

When the erythrocytes were washed three times with isotonic sodium chloride before incubation with glycine, the curve for protoporphyrin formation was found to be similar in form to that shown in Fig 1, but maximum synthesis was depressed by about 80 per cent (Fig 2)

That the inhibition of protoporphyrin formation by higher oxygen tensions is reversible is shown in Fig 3 We have not been able to demonstrate marked degradation of protoporphyrin at 'inhibitory' oxygen tensions

During the biosynthesis of porphyrins, 'aerobic' reactions are known to be required for the formation of δ-aminolævulic acid, but not again until near the end of the biosynthetic pathway, for the final formation of the vinyl side-chains, and possibly also for the oxidation of a porphyrinogen to the porphyrin level[4,5] The rising slopes in Fig 1 reflect these requirements for oxygen, it appears that much lower oxygen tensions suffice for reactions prior to coproporphyrin formation than for the formation of protoporphyrin If the decreased amounts of protoporphyrin found at higher oxygen tensions are not due to degradation reactions, they would appear to be due to an inhibition by oxygen of some step in the synthetic pathway As pointed out above, this inhibition is reversible, and it must lie far back in the pathway because coproporphyrin synthesis also is decreased at those high levels of oxygen (Fig 1) at which protoporphyrin synthesis is decreased

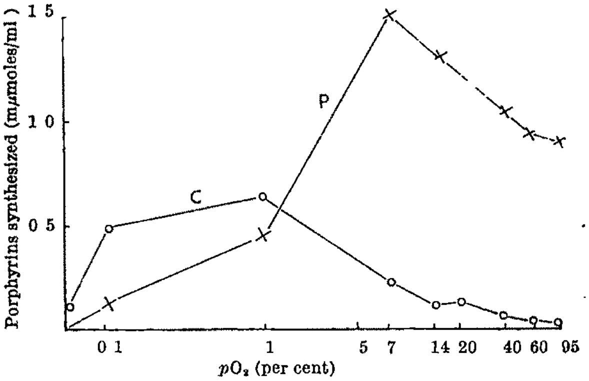

Fig 2 The control by oxygen of porphyrin synthesis from glycine in washed chicken erythrocytes The cells from 25 ml blood were washed and incubated for 10 hr , as described in the text *C*, coproporphyrin , *P*, protoporphyrin No protoporphyrin was formed in the complete lack of oxygen

It appears possible that the control of porphyrin synthesis by oxygen tension may play an important part in cytochrome adaptation in bacteria, though the production of some cytochromes by obligate anaerobes must be considered There is also evidence[8] that the synthesis by micro-organisms of some colourless enzymes is controlled by oxygen tension

It is interesting to relate the present findings to animal physiology The stimulatory effect of anoxia upon erythropoiesis in higher animals[9] and in Crustacea and other invertebrates[10] is well known, and it has also been shown that high tissue-oxygen tensions lead to decreased erythropoiesis[11] In physiological studies, it has been difficult to separate the effects upon erythropoiesis of oxygen tension from those of endocrinological or other 'plasma'

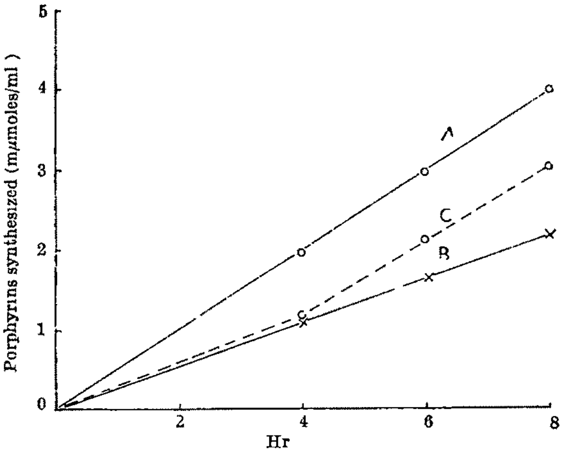

Fig 3 The reversibility of the inhibition by high oxygen tension of protoporphyrin synthesis Whole chicken blood was incubated as described in the text Curve *A*, 5 per cent oxygen , curve *B*, 95 per cent oxygen , curve *C*, 95 per cent oxygen for 4 hr , then 5 per cent oxygen for 4 hr

factors[9] The present experiments indicate that there is an oxygen effect exerted directly on a step or steps in the biosynthetic pathway to hæm In studies *in vitro* of bone marrow from rabbits damaged by X-irradiation, and of normal marrow[12], it has been demonstrated that hæm synthesis precedes that of globin , oxygen tension, by limiting directly the synthesis of hæm, may be expected to limit hæmoglobin synthesis That the rate of maturation of erythrocyte precursors *in vitro* increases with oxygen tension to a maximum and falls with further increases of oxygen has been demonstrated[13], and it appears possible that maturation of these cells may be linked to hæmoglobin synthesis

Since the above was written, Lascelles[14] has shown that the formation of bacteriochlorophyll in *Rhodopseudomonas spheroides*, incubated in the dark, reaches a maximum at a pO_2 of about 6 per cent and is depressed at higher oxygen tensions The formation of δ-aminolævulic acid, and the conversion of this to porphobilinogen, were both found to be sensitive to oxygen tension in *R spheroides* We have not investigated the sensitivity of these particular reactions to oxygen in chicken erythrocyte preparations, but we have clear evidence (to be published) that some reaction after the formation of porphobilinogen and prior to the formation of uroporphyrin is inhibited by oxygen tensions higher than about 7 per cent A preliminary report of this work has been given[15] and it will be described in detail elsewhere It thus appears that in tetrapyrrole biosynthesis, oxygen may control a number of sensitive steps which could vary both qualitatively and quantitatively from tissue to tissue

POSSIBLE ROLE OF HIGHER PROPRIOCEPTIVE CENTRES IN THE PERCEPTION OF VISUAL SPACE AND IN THE CONTROL OF MOTOR BEHAVIOUR

By Dr B. GUREVITCH

Laboratory of the Physiology of the Visual Analyser, Pavlov Institute of Physiology of the Academy of Sciences of the U S S R , Leningrad

THE variability of oriented motor acts may lead to the assumption that the transformation of proprioceptive impulses into signals for the appropriate regulation of a movement going on greatly depends on temporary changes produced by the conditioning stimulus in the higher centres to which they are flowing Admitting that orientation in space is mainly based on ontogenetic experience, we are led to suppose that the 'Pavlov feedback'[1]—the temporary connexions of the higher proprioceptive centres—play an important part in the organization of the perception of space

This view is not generally accepted Thus, in visual space perception theory, Sherrington's concept[2] identifying the 'muscle sense' of the eyes with the inflow of impulses from the sensory nerve endings in the extrinsic eye muscles is opposed by the generally accepted Helmholtz's theory[3] affirming that we evaluate the direction of our sight on the basis of "the innervation impulses we must apply to transfer the eye in the intended position"

According to a recent suggestion[4], the normal human perception of space "is organized on the conservative principle of a null-hypothesis" and should require no analysis in terms of specific neural events Such a rather paradoxical view will scarcely satisfy the physiologists interested in the investigation of nervous mechanisms subserving normal life functions

Now, from Helmholtz's typical 'outflow' theory it would follow that for every eye rotation a corresponding innervation pattern is quantitatively 'predetermined' by the 'sense of innervation' Hence, as the eyes in their movements (especially horizontal) constitute a system with constant mechanical load, equally directed eye fixation movements of a subject in equal conditions ought to follow the same course

To study eye rotations under the action of the 'muscle sense', conditioned fixation movements have been systematically investigated in 14 normal subjects In response to the conditioning sound stimulus (400/sec , 30 db above audibility threshold, applied during 1½ sec) the subjects had to turn their eyes in total darkness and to maintain them in the directions in which formerly visible points appeared and were fixed A total of 14,000 large-scale electrooculographic records were examined, and the results analysed statistically

Previously, it has been shown[5] that conditioned eye 'muscle sense' has significant directional power, for, in the mean, 40 per cent of all conditioned eye movements were found to be as precisely directed towards the goal as fixation movements to visible objects, and, once attained, a given position of the eyes was further as exactly maintained in complete darkness

It was no less significantly demonstrated (Fig 1) that even in a series of successive trials, the saccadic movements of the same subject's conditioned eye fixation, transferring the line of regard into one and the same exact final direction, nevertheless differ essentially one from each other as regards characteristics and composition of the saccade, and namely as

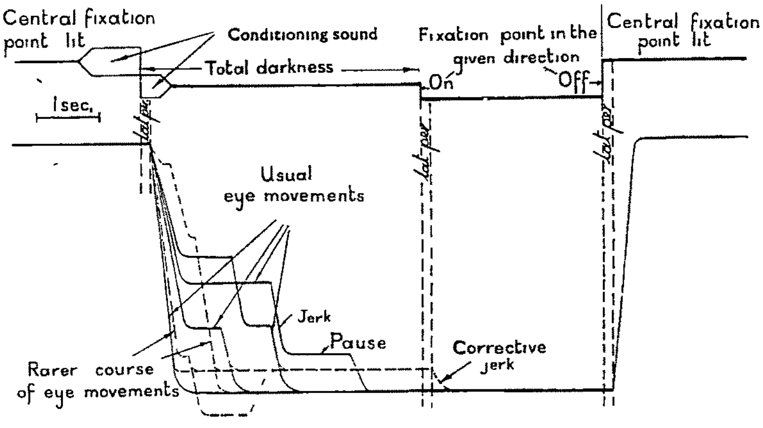

Fig 1 Representative scheme showing typical variability of equally directed precise (——) or imprecise (– – –) conditioned eye fixation movements in successive trials Abscissae time, ordinates eye displacement during trials From more than 2,000 records of conditioned eye movements in the dark of six subjects, in various given directions from 6° 20′ to 35° off the centre in the horizontal plane Optically elicited and conditioned changes in fixation are preceded by latent periods of about 0 15 sec lat per = latent period

to (*a*) the number of single eye jerks in it (for example, from 1 to 3, and up to 6 jerks in the total saccade), (*b*) the size of these jerks (varying, most generally, from 30 to 100 per cent of the total fixation movement, and in extreme cases from 15 per cent up to 120 per cent of its total size), (*c*) the duration of pauses between successive jerks in the saccades (habitually, from 0 04 to 0 7 sec , and up to 1 92 sec), (*d*) the angular speed of the eye movement in jerks of equal size (from 60 to 140 per cent, and not infrequently up to 200 per cent of its mean value) In some cases reversals have been observed in the usual succession of diminishing jerks, and in some other cases excessive jerks have been recorded, followed by corrective jerks in the opposite direction

Such a fundamental variability of the composition of equally directed saccadic fixation movements characterizes conditioned eye rotations of every size in the horizontal plane as well as in vertical and in diagonal planes We may conclude that conditioned eye movements of equal total size and direction, just like motor acts of the organism as a whole, are generally produced by essentially variable sequences of innervation impulses, which is inconsistent with the innervation theory On the other hand, the now well-known proprioceptors[6] of the extrinsic eye muscles are the only sensory organs firing during eye rotations in total darkness, and this proprioceptive feedback is used to bring the position of the eyes into accordance with the temporary central changes brought about by the conditioning stimulus Thus the observations strongly support the hypothesis that the 'muscle sense' of the eyes is mainly controlled by temporary changes in the higher proprioceptive centres, and it must be noted that such a mechanism would form a physiological basis for visual illusions arising in cases of dissociation between the actual eye position and the evaluation of the line of regard, which in fact depends on conditioned fixation reflex training

Because of the restriction of nerve connexions engaged and the constancy of mechanical load during movement, the conditioned eye fixation reflex may be considered as a simple physiological model of more complicated motor behaviour acts

It appears that to remove apparent contradictions between 'peripheral' theories of behaviour control (like Sherrington's) and 'central' theories (like Helmholtz's), Pavlov's theory must be applied to sensory arcs of the conditioned reflex Fig. 2 represents a hypothetical scheme based on Pavlov's concept of temporary cerebral kinæsthetic feedback The external stimuli, having formerly coincided with reactions fulfilled and re-inforced, on eliciting a reaction by the way of its effectory centre, simultaneously produce in the higher proprioceptive centres changes just like those which, beforehand, became reinforced at the fulfilment of the reactions During the course of the reaction, the impulses ascending to the higher proprioceptive centres from the sensitive endings in the effectory organs are constantly re-codified according to the functional state of these centres and, being thus transformed into signals of correction, take part in the regulation of the reaction until its fulfilment and repeated reinforcement Thus, it appears that behaviour acts remain on the whole adequately directed, because of the regulation during their course of the efferent nerve supply by the higher proprioceptive centres, according to changes brought to these centres by conditioning stimuli

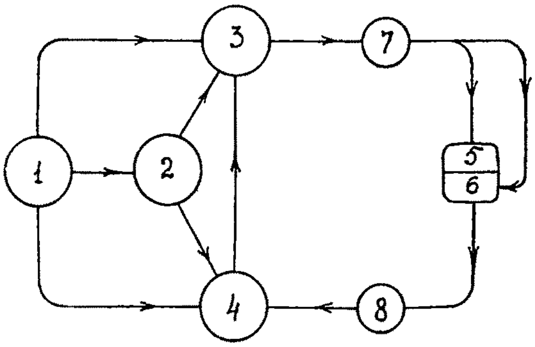

Fig 2 Hypothetical scheme of the central 'sensory' control of behaviour, 1, cortical representation of the conditioning stimulus, 2, cortical centre of the unconditioned reaction, 3, cortical effectory and 4, cortical sensory centre of the conditioned reaction, 5, effectory organ and 6, sensory endings in it, 7, 8, subcortical centres Arrows show the supposed directions of the main innervation flows engaged

It is only in the frame of the conditioned changes in the higher sensory centres that the afferent impulses from the effectory organs get their full meaning for the organism 'Muscle sense' arises from co-operation and mutual control, as behaviour acts are going on, of certain sensory events of external and internal origin, this co-operation and mutual control being rendered possible by the conditioned reflex mechanisms Thus, the mechanisms of elaboration of temporary changes in the higher proprioceptive centres may be regarded as probably the more general physiological basis of psychic space perception phenomena

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, November 30

Royal Society (at Burlington House, Piccadilly, London, W 1), at 2 30 p m —Anniversary Meeting

Institute of Metal Finishing (in the Canterbury Room of the Charing Cross Hotel, London, W C 2), at 2 45 p m —Mr A A B Harvey "The Role of the Scientific Society" (Presidential Address)

University College (in the Physiology Theatre, Gower Street, London, W C 1), at 5 p m —Prof E P Kennedy (University of Chicago) "The Biosynthesis of Complex Lipids" * (First of two lectures in Biochemistry Further lecture on December 7.)

Royal Institution, Library Circle (at 21 Albemarle Street, London, W 1), at 5 30 p m —Dr L Pearce Williams "Faraday Through His Manuscripts"

Royal Geographical Society (at 1 Kensington Gore, London, S W 7), at 8 30 p m —Prof C von Furer-Haimendorf "Sherpas of Eastern Nepal"

Tuesday, December 1

University of London (in the Anatomy Theatre, University College, Gower Street, London, W C 1), at 1 15 p m —Prof R E D Bishop "Vibration Problems in Engineering" *

Institution of Electrical Engineers, Measurement and Electronics Sections (at Savoy Place, London, W C 2), at 5 30 p m —Dr L Essen, Mr J V L Parry and Mr J McA Steele "Frequency Variations of Quartz Oscillators and the Earth's Rotation in Terms of the N P L Cæsium Standard"

University of London (at Imperial College of Science and Technology, London, S W 7), at 5 30 p m —Prof H K Porter "Physiology has No Frontiers" (Inaugural Lecture)

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 5 30 p m —Dr J L Gowans "The Lymphocyte" * (Twelfth of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation Further lectures on December 3, 8, 10)

Plastics Institute (at the Wellcome Building, 183–193 Euston Road, London, N W 1), at 6 30 p m —Mr M R E Ashenden 'Plastics and the Law"

Royal Aeronautical Society (at 4 Hamilton Place, London, W 1), at 7 p m —Dr I M Hall "Transonic Flow Over Swept Wings"

Wednesday, December 2

Institute of Petroleum (at 61 New Cavendish Street, London, W 1), at 5 30 p m —Mr J Marechal and Mr P de Radzitsky "Potentialities of Urea in Dewaxing Middle and Heavy Distillates"

Institute of Information Scientists (at the Berners Hotel, 10 Berners Street, London, W 1), at 6 p m —Discussion on "Languages in Information Work—To What Extent is Competence in a Foreign Language an Essential Qualification for an Information Scientist?"

Wednesday, December 2—Thursday, December 3

Iron and Steel Institute (in the Great Hall, Caxton Hall, Caxton Street, London, S W 1, and the Hoare Memorial Hall, Church House, Great Smith Street, London, S W 1), at 9 30 a m daily—Autumn General Meeting

Thursday, December 3

University of London (in the Anatomy Theatre, University College, Gower Street, London, W C 1), at 1 15 p m —Mr P R Bell "The Origin of Indian Corn" *

Royal Society (at Burlington House, Piccadilly, London, W 1), at 4 30 p m —Mr F H C Edgcombe and Prof R G. W Norrish, F R S "A Study of the Mechanism of Photochemical Electron Transfer Processes in Solution", Mr I M Dawson and Mr E A C Follett "An Electron Microscope Study of Synthetic Graphite"

Institute of Marine Engineers (joint meeting with the Institute of Naval Architects, in the Weir Hall, 10 Upper Belgrave Street, London, S W 1) at 4 45 p m —Prof G Aertssen "New Sea Trials on the Sandblasted *Lubumbashi*"

University of London (at the London School of Economics and Political Science, Houghton Street, London, W C 2), at 5 p m —Dr E R Leach "Rethinking Anthropology"* (Malinowski Memorial Lecture)

Royal Society of Arts, Commonwealth Section (at John Adam Street Adelphi, London, W C 2), at 5 15 p m —Mrs Mildred Valley Thornton "Indians of British Columbia"

Institution of Electrical Engineers (at Savoy Place, London, W C 2) at 5 30 p m —Mr C B B Wood and Mr I J Shelley "The Transmission of News Film over the Trans-Atlantic Cable"

Society of Chemical Industry, Microbiology Group (joint meeting with the Society for Applied Bacteriology, at the Royal Society of Medicine, 1 Wimpole Street, London, W 1), at 6 15 p m —Dr F Brown "Infective Ribonucleic Acid from the Virus of Foot-and-Mouth Disease"

Friday, December 4

Institution of Electrical Engineers, Medical Electronics Discussion Group (at Savoy Place, London, W C 2), at 6 p m —Discussion on "Nuclear Magnetic Resonance", opened by Dr N Sheppard and Dr R E Richards

Society of Dyers and Colourists (at the Royal Society, Burlington House, Piccadilly, London, W 1), at 6 p m —Mr R C Oakley "Dyeing of Ribbons", Mr R Woods "Dyeing of Carpet Yarns"

Royal Institution (at 21 Albemarle Street, London, W 1), at 9 p m —Dr H A Thomas "Electronic 'Brains'"

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Lecturers or Assistant Lecturers (suitably qualified graduates, with some experience in any of the branches of electrical engineering) in the Department of Electrical Engineering—The Registrar, The University, Manchester 13 (November 21)

Lecturer in Telecommunication, to undertake undergraduate and postgraduate teaching and to supervise research involving information analysis and experimental work, including the human element—Head of the Electrical Engineering Department, Imperial College of Science and Technology, Exhibition Road, London, S W 7 (November 24)

Lecturer (with a degree in psychology or equivalent and experience of teaching and clinical work) in Educational Psychology—The Registrar, University College, Swansea (November 28)

Senior Lecturer and a Lecturer (preferably with a major interest in applied thermodynamics or applied mechanics, especially the theory of machines) in Engineering (Mechanical)—The Registrar, The University, Manchester 13 (November 28)

Senior Lecturer, Lecturer, and an Assistant Lecturer in the Department of Mechanical Engineering—The Registrar, Royal Technical College, Salford, Lancs (November 28)

Assistant Lecturer (Demonstrator) in Anatomy to undertake teaching and research , and a Research Assistant (with an honours degree in zoology or medical sciences, and preferably a knowledge of German) in the Department of Anatomy, for work mainly on the central nervous system—The Secretary, University College London, Gower Street, London, W C 1 (November 30)

Lecturer in Applied Mathematics at Victoria University of Wellington, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (New Zealand, November 30)

Research Officer (with veterinary qualifications), for studies on virus of foot-and-mouth disease in farm animals—The Secretary, Research Institute (Animal Virus Diseases), Pirbright, Surrey (November 30)

Senior Lecturer in Chemistry at Victoria University of Wellington, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (New Zealand, November 30)

Research Assistant (with a first- or second-class honours degree in chemistry, or alternatively, graduate member of the Royal Institute of Chemistry) in Chemistry—The Principal, Coventry Technical College, Butts, Coventry (December 1)

Lecturer (with experience in either heavy electrical machinery or of power transmission and distribution) in Electrical Engineering—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (December 4)

Assistant or Associate Professor of Applied Mathematics—The Chairman, Department of Mathematics, McMaster University, Hamilton, Canada (December 10)

Senior Lecturer, or Lecturer (Grade I) in Botany at University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (December 12)

Senior Lecturer or Lecturer in Experimental Pharmacology—The Secretary, The University, Aberdeen (December 14)

Chair of Physics, Chair of Geology, Chair of Zoology, and Chair of Bacteriology in the University of Khartoum—The Registrar, University of Khartoum, c/o Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (December 15)

Empire Rheumatism Council Fellow (with medical or scientific qualifications), to prosecute research in the field of rheumatism—The General Secretary, Empire Rheumatism Council, Faraday House, 8–10 Charing Cross Road, London, W C 2 (December 15)

Assistant Lecturer or Lecturer in the Department of Zoology—The Registrar, The University, Liverpool (December 19)

Lecturer or Assistant Lecturer in Pharmaceutics at the University of Malaya (Singapore Division)—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (January 15)

Imperial Chemical Industries Research Fellows in Chemistry, Physics, Metallurgy, Engineering, Geology, Agricultural Science and related subjects—The Registrar of the University of Wales, University Registry, Cathays Park, Cardiff (March 7)

Assistant Biochemist (Basic grade) (with an appropriate science degree, or Associate or Graduate Member of the Royal Institute of Chemistry) in the Department of Pathology—The Superintendent, Northampton General Hospital, Northampton

Assistant, Grade B, in Physics—The Clerk to the Governors, Woolwich Polytechnic, London, S E 18

Head of the Department of Aeronautical and Mechanical Design—The Registrar, Hatfield Technical College, Hatfield, Herts

Master to teach Mathematics, with a good share in sixth form work—The Headmaster, Bedford School, Bedford

Master to teach Science and Mathematics up to Middle School level—The Headmaster, King's School, Rochester, Kent

RESEARCH ASSISTANT TO WORK IN THE PHARMACOLOGY DEPARTMENT on inflammation and anti-inflammatory substances—The Dean, Guy's Hospital Medical School, London Bridge, London, S E 1

SENIOR ASSISTANT PHYSICIST (with some experience in medical physics) to act as deputy to the Principal Physicist and to take responsibility in radiation physics and isotope work—The House Governor, King's College Hospital, Denmark Hill, London, S E 5

ORGANIZATION OF SCIENTIFIC AND TECHNOLOGICAL RESEARCH IN BRITAIN

IN the election manifesto of the Conservative Party released on September 11, it was stated that, as the first of five measures to promote technological advance in Britain and to translate this into productive capacity with a high and rising rate of investment, one Cabinet Minister would be given the task of promoting scientific and technological development "While it would be wrong to concentrate all Government scientific work into a single Ministry, this Minister for Science will have responsibility for the Department of Scientific and Industrial Research, the Medical and Agricultural Research Councils, the Nature Conservancy, the atomic energy programme, and the United Kingdom contribution to space research" The manifesto added that the development of nuclear energy for peaceful purposes would be pressed ahead, a conference called for those concerned in industry and education to forward the spread and understanding of automation, while besides encouraging new inventions and the development of new techniques, further changes would be made from time to time in the functions of Ministers as might be necessary to meet modern needs

This emphasis on the importance of science in the national welfare and the need to adapt administration to ensure that due account is taken of scientific and technological advance, was followed on September 17 by a special statement from the Labour Party entitled "A New Deal for Science" This statement proposed the appointment as "Minister of Science" of a senior Minister with general responsibility for scientific affairs and the authority to perfect and carry out by and through the various Ministries concerned a carefully planned programme to use modern science to the full This programme would include a further expansion of scientific and technological education, more scientific training in the schools, and consequently more science teachers, a substantial increase in the number of research and development contracts and Government grants to individual firms for approved long-term research projects , and the establishment under the Minister of a scientific and technical planning board to advise on the direction of industrial research and development, on the awards of research contracts and on the grants to individual firms

Both major political parties of Britain have thus committed themselves to some modification of the organization of research and development in the country, and of the means by which scientific and technical advice is presented at the highest level Neither statement gave sufficient information to allow a sound judgment as to which is the more promising proposal, but now that Mr Macmillan has been returned to power he has lost no time in making the promised appointment The Cabinet changes announced on October 14 included the appointment of Lord Hailsham as Lord Privy Seal with the general duty of promoting scientific and technological advance in consultation with the departmental Ministers No Ministry of Science is to be created , indeed, it is pertinent to observe that Lord Hailsham gave last April a reasoned argument against the practicability of any such appointment, and it is clear that Ministers will retain executive responsibility for scientific matters within their own departments and that no attempt will be made to limit the freedom and initiative of universities or industry in determining the content of scientific education or the direction of research

Lord Hailsham, who relinquishes the chairmanship of the Conservative Party, takes with him, from the Lord Presidency of the Council, ministerial responsibility for the work of the Department of Scientific and Industrial Research, the Medical Research Council, the Agricultural Research Council and the Nature Conservancy , this constitutes a definite break with the structure built up in the past forty years and more He will also assume responsibility for the work of the Atomic Energy Authority, the Atomic Energy Office, the Overseas Research Council and supervision of the British contribution to space research At a Press conference on October 14, Lord Hailsham indicated that his task would be to do some fundamental thinking on the relations between Government and science, and he stressed his anxiety to do nothing to interfere with the independence of the Government-financed scientific bodies Essentially he confirmed the views he expressed last April to the Institution of Chemical Engineers, and indicated that the appointment was only likely to show results after a long period and that its terms were not such as could easily be put down on paper

It is thus unlikely that Lord Hailsham's appointment contributes anything material at the moment to the formal organization of the scientific effort of Great Britain, either in research and development or in other fields Lord Hailsham's addresses to the Institution of Chemical Engineers and the Institute of Physics last year showed how well aware he is of the dependence of our scientific and technical effort not merely on the resources allocated for such work, but also on education, and the interlocking of problems of application with those of defence as well as of industry Equally he recognizes that if educational and scientific institutions are to function efficiently, they must retain complete integrity, and accordingly a high degree of independence His conception of a scientific policy—and presumably in this he includes technological policy—is of a partnership in which Government, teaching institutions, research institutions and industry all play important and interrelated parts It could well be that Lord Hailsham was selected for his new office because he has publicly stressed the need for a more intelligent understanding of the forces at work and has indicated that he was already thinking deeply about the relations between Government and science

There can be little doubt that Lord Hailsham intends to consider whether the new arrangements are adequate, and whether they can be improved; but there seems little reason to fear that new administrative arrangements will be created without due forethought and consultation, or new policies concerted and applied unimaginatively or without due regard to the essential conditions for scientific work It may be expected that Lord Hailsham's inquiries and thinking will lead to the elimination of some of the duplication of effort that can be found, though it is improbable that he will fail to recognize that there are occasions when such duplication is an advantage and an asset rather than waste What is important is that Lord Hailsham appears to be bringing to his task the breadth of vision, the imagination and something of the understanding of the mind of the scientist that are essential for success.

What is more important, perhaps, is that Lord Hailsham himself recognizes that the task of Minister of Science or for Science is inherently impossible for any one man to discharge, and he is likely to look rather for the administrative arrangements which may best permit the Government as a whole to take full account of the scientific and technical factors involved in its decisions on policy and to ensure an adequate and balanced apportionment of our resources in man-power, in finance and in materials for scientific and technical work generally If also he examines the question whether, as has been alleged, the authority of scientists in the key Departments of State is really being dangerously eroded, he will have done as much as can fairly be expected of any one man

The statement, "The First Minister for Science", which Lord Hailsham has since issued (see p 1263) of this issue of *Nature*) confirms all this He emphasizes the need for other Ministers in the Government to be scientifically minded if his work is not to be incomplete, and he stresses again that his appointment should impel scientists themselves to take a share in thought about scientific policy Such a policy, he reiterates, cannot be the product of Government thinking alone

Several specific points in this statement should also be noted Lord Hailsham believes that Government science, and perhaps all British science, is at present too parochially minded, too departmentalized and lacking in broad vision He believes also that the Advisory Council on Scientific Policy holds the key to the situation, and announces his intention of relying more upon this Advisory Council for general advice on questions of scientific policy With this welcome indication that the Advisory Council's authority is to be restored comes the admission at last that the office of the Lord President of the Council has been under-staffed, and the warm welcome which scientists generally will extend to the whole tenure of Lord Hailsham's statement will be accompanied by greater confidence in that he is now likely to enjoy the services of a larger and more flexible office staff Lord Hailsham's efforts to tackle such questions as the general balance of scientific effort, to forge closer ties between Government research stations and institutes and the universities, and to foster alike applied research and increased benefactions for universities and colleges, will carry the greater conviction in this context, and it should also assist to enlist the support of scientists and technologists generally, for which he pleads

Above all, it is important that Lord Hailsham's appointment should be regarded as a challenge to scientists and technologists generally to think deeply about the issues displayed in this statement, many of which were set forth earlier by Lord Hailsham and Sir Hugh Beaver in their addresses to the Institution of Chemical Engineers It should not be forgotten that, however admirably an administrative structure may be devised and established, its effectiveness will always largely depend on the men who use it Apart, too, from the perennial temptation to look for rapid political returns rather than the long-term gains which a sound scientific policy would offer, the penetration of science into the more backward industries and into some Departments of State is a matter both of education and of personal influence Personalities again may play a vital part, especially when it is a matter of securing co-operation

It is accordingly worth while to look carefully at the way previous arrangements have functioned before deciding on further changes Valuable clues may well be found as to the essential conditions, and even in the context of the new responsibilities which Mr Macmillan has entrusted to the office of Lord Privy Seal, Lord Hailsham will not find it easy to give better services to science than have been rendered by some of his predecessors as Lord President of the Council, notably Lord Balfour and Lord Waverley The late Sir Walter Morley Fletcher has written of Lord Balfour's deep interest in the work of the Medical Research Council, the chairmanship of which he retained when he became Lord President in spite of the anomaly Lord Balfour was no less interested, however, in the work of the Department of Scientific and Industrial Research, and sought strenuously to increase effective contact between scientists themselves and also between them and the administrative departments, promoting for this purpose the establishment of the Committee of Civil Research, the counterpart of the Committee of Imperial Defence

Besides the testimony of members of these Councils and Committees to the encouragement and inspiration derived from the experience of encountering a statesman who possessed both the power to help research and the imagination to understand its value to the State, there is on record the further services to science which Lord Balfour rendered at the Imperial Conference of 1926 Balfour said at the time that he regarded the work of the Research Sub-Committee of the latter Conference, over which he presided, as only second in importance to that of the Committee on Inter-Imperial Relations, and in its proposals for co-ordinating research he sought to forge new cultural links between all parts of the Commonwealth, through the departments and individuals engaged in scientific work in every field The recently formed Overseas Research Council owes something to the foundations thus laid, and it might well be worth re-examining the circumstances which have held back for a generation such a promising start

If there is thus on record how much can be achieved by a Minister with vision and imaginative understanding of the needs of the scientist, there is also testimony to the value of a Cabinet Minister himself trained as a scientist Such tribute has been paid in regard to both Sir Stafford Cripps and Lord Waverley, notably in regard to the latter by Earl Attlee and also by Lord Winster, who during the Second World War had been given responsibility as a Cabinet Minister for the promotion of science and was for a time a member of the Cabinet's scientific advisory committee (out of which the Advisory Council for Scientific Policy later developed) when Lord Waverley was Lord President of the Council Lord Hailsham himself has stressed the authority which Lord Waverley could derive in scientific matters from being able to speak as a science graduate Lord Bridges has testified to the outstanding quality of Lord Waverley's work as Lord President of the Council, not only to his capacity for understanding and sound judgment, but also to the way in which he worked so far as possible through departmental staffs without building up any large organization of his own, and also to the importance of the complete confidence which existed between the Lord President and the Prime Minister

Lord Bridges, in his Royal Society memoir, referred particularly to Lord Waverley's services to science both while he was Lord President during 1940–43 and afterwards, particularly in what might be called the scientific administration of the development of nuclear energy It is too early yet to expect the critical biography of Lord Waverley which might illuminate these arrangements more fully, but it is important that they should be examined as fully as possible in the light they could throw on the kind of arrangements which are desirable to-day They suggest, for example, that any constructive thinking should include a careful appraisal of the functioning of both the Advisory Council for Scientific Policy and the Research Defence Policy Committee

Even this cursory review indicates the critical importance of personal factors, and there is a further reason for looking closely into this aspect The late Sir Henry Tizard, who has claims to be considered as a military scientific genius, was very successful in his joint chairmanship of the Advisory Council for Scientific Policy and the Research Defence Policy Committee during 1946–52 Nevertheless, in spite of the conspicuous services he had rendered even before the Second World War in developing defence research policy and later in encouraging the development of operational research, in 1942 he suddenly resigned from most of his official appointments to become president of Magdalen College, Oxford Sir Henry was one of the easiest of colleagues, so any administrative structure which led to such a decision is *ipso facto* suspect Incidentally, in their Romanes and Haldane Memorial Lectures, respectively, both Lord Waverley and Sir Henry Tizard have recorded considered opinions and constructive proposals for providing the Government with more authoritative guidance in technical matters

It may be hoped that Lord Birkenhead's official biography of Lord Cherwell will in due course throw some light on these matters Sir George Thomson in his Royal Society memoir refers briefly to the existence of conflicts of opinion between Cherwell and Tizard which were well known in the scientific world, but no light is thrown on this by Sir Roy Harrod's more recent personal memoir, "The Prof ". He does, however, indicate another aspect of some interest in considering the functions of a Minister of Science It is the personal relations between Lord Cherwell and Sir Winston Churchill, first as First Lord of the Admiralty and later as Prime Minister, rather than Lord Cherwell's own subsequent position in the Cabinet as Paymaster-General that are of primary interest Lord Cherwell was able to render his great contribution to the national war effort because of the extent to which he possessed Mr Churchill's confidence and understanding

What Sir Roy Harrod writes of this relationship will bear pondering Where such confidence and understanding can be established, from whatever beginning, the outcome may well be as effective for the promotion of science and technology as when the Cabinet Minister concerned has himself been trained in science It might possibly be a waste of scarce and highly trained man-power, even if it were possible, to provide every Cabinet Minister carrying departmental responsibilities involving highly technical and scientific matters or research with a scientific adviser of Cherwell's quality for his personal assistant The results in any event would depend alike on the quality of that adviser's mind and on the personality of the Minister, as well as on the intimacy of the relations between him and his adviser , but it should be clear enough that it is not sufficient for scientific and technical advice to be presented at one point alone The effective formulation of policy where science and technology are concerned will come when such factors are accurately assessed, not by one Minister only, but all the Ministers concerned

There could well be found here the reason why the single-handed efforts of Lord Balfour a generation ago and the advocacy of such men as Lord Samuel have hitherto failed of full fruition For that reason alone the functioning of the advisory committee compared with that of the personal assistant or adviser requires further examination Moreover, in Sir Roy Harrod's memoir of Lord Cherwell the emphasis is on the contribution which Lord Cherwell and his statistical section made to quantitative thinking about the conduct of the War, and Sir George Thomson's memoir appears to confirm that this was the most important characteristic of Lord Cherwell's contribution This again suggests that there is something to be learned from the functioning of this section and the work of the Central Statistical Office established in 1941.

There can be no doubt as to the immensity of the task which Lord Hailsham has undertaken, and the diversity of problems he will need to consider. Now that he has divested himself of his party political responsibilities as chairman of the Conservative party, he appears to be as good a choice as could have been made. His experience as Lord President of the Council has already given him a close insight into some of the problems involved and his speeches have shown both that he is thinking deeply about the real issues and that he is averse to hasty and unilateral decisions.

If it should be reiterated that Lord Hailsham's appointment represents no essentially new departure, similar positions having been occupied by Lord Balfour more than thirty years ago and by Lord Winster and possibly Lord Waverley in the Second World War, the scale and range of problems now confronting him cannot be compared with those presented to any predecessor in peace-time. He will doubtless examine the functioning of the Advisory Council for Scientific Policy and its interrelations with the Defence Research Policy Committee, as well as the specific problems and relations of the several research councils and organizations for which he is specifically responsible. There is the question of departmental research as against centralized research, for example, under the Council for Scientific and Industrial Research. There is a whole range of problems presented by the industrial research associations and the stimulation of research and its exploitation in industry. There is the matter of the balance of our research effort generally and the place of the universities and the independent research institutions and the resources at their disposal and the way in which Government policy can best strengthen such resources without infringing academic or professional autonomy. There are problems which will lead Lord Hailsham into the educational field, as when he considers our resources in scientific and technical man-power and their expansion, as well as their most effective deployment.

Nor are all these problems sharply separated. The support, for example, which the Department of Industrial and Scientific Research already gives to the universities, both by way of grants to individuals for postgraduate study and to university departments in support of specific research projects, already takes it within the orbit of the University Grants Committee, and this holds in varying degree for the other research councils also. It is arguable that nowhere below the level of the Prime Minister himself can all the responsibilities involved rest in one man, if indeed the task is not too immense for any person to discharge it alone. There, of course, we touch the question of Cabinet responsibility, but without entering on any such discussion it might be observed that the Cherwell–Churchill relation seems at least to support the view that a Minister who carried general responsibility for scientific (and presumably also technological) matters might be able to give the Cabinet sufficient detailed advice to clarify and facilitate decisions either in the Cabinet or by the Prime Minister himself. Lord Hailsham is obviously approaching these questions without preconceived ideas as to whether changes are required in our present arrangements, and if so, what changes for the better are possible, and he has at his disposal much valuable evidence not merely from Lord Waverley, Lord Bridges and Sir Henry Tizard, but also from others like Lord Hankey, Lord Ismay and Sir Henry Dale. Whatever the administrative structure may be, there is one essential condition if it is to function smoothly: effective measures must be taken to eliminate or bridge the gap between what Sir Charles Snow has described so vividly as the two cultures. The effective use of science and technology for the public welfare and in the affairs of State will not be ensured by establishing a Ministry of Science or appointing a special Minister. It will be secured in the measure, and only in that measure, in which Ministers and administrators, the Departments of State, the public corporations, industry and the public generally are aware of the conditions and nature of scientific work, understand in some degree what science is doing and are prepared to provide the necessary support.

THE PRINCIPLES AND PRACTICE OF CROP PROTECTION

The Scientific Principles of Crop Protection

By Hubert Martin. Fourth edition. Pp. viii+359. (London: Edward Arnold (Publishers), Ltd., 1959.) 65*s.* net.

Advances in Pest Control Research

Vol. 2. Edited by R. L. Metcalfe. Pp. vii+426. (New York: Interscience Publishers, Inc.; London: Interscience Publishers, Ltd., 1958.) 94*s.*

Recognition of Diseases and Pests of Farm Crops

By Ernst Gram, Prosper Bovien and Chr. Stapel. (Danish Agricultural Information and Advisory Aids Service.) Pp. 128+112 colour plates. (Cambridge: W. Heffer and Sons, Ltd., 1958.) 35*s.* net.

The Control of Pests and Diseases in Agricultural and Horticultural Crops

By G. L. Hey and K. Marshall. (Agricultural and Horticultural Students Series.) Pp. 172. (London: Vinton and Co., Ltd., 1958.) 12*s.* 6*d.* net.

TO say that, nuclear wars apart, the greatest problem of the future will be to feed the rapidly increasing human population is none the less true for being trite. Happily there is no need to think it is insoluble. Average crop yields are so low that the scope for improvement is enormous, and starvation can be avoided for a long time simply by improving the health of crops. Over much of the world most crops are left to fend for themselves, unaided in their struggle with pests and diseases. What annual toll these predators take cannot be estimated at all accurately, but there is little doubt that human beings will have at least twice as much to eat when they stop sharing their crops with pests and diseases.

The four books listed above differ greatly in content and immediate purpose, but all have the same ultimate aim of increasing yields by protecting plants against their pests and diseases. They make it clear that many of the losses now suffered are legitimately described as avoidable, in the sense that they could be avoided by applying existing knowledge more widely, but it is also clear that much new knowledge will be needed before all losses come into this category Between them the books also show how complex and varied are the problems entailed in improving the health of crops First, there are the research problems, diagnosis of the cause, the biological study of the pest or pathogen to find where it comes from, how it spreads and whether there is a stage in its life history at which it is especially open to attack, and this to be followed by tests of pesticides, of variations in cultural practices or of seemingly resistant varieties Secondly, when research has produced a control method, there still remains what is often the more difficult task of getting it established in practice, and even with this achieved the position must be closely watched to ensure that the method remains effective and has no undesirable side effects.

"The Scientific Principles of Crop Protection" is one of the few books that attempt to cover the whole subject, and a new edition was long over-due, for most of the insecticides currently used have been discovered since the third edition was published in 1940 The title has been changed to the extent that 'plant protection' has become 'crop protection', but the presentation and approach are as before The new edition might have been even more welcome had the changes been greater, for it is now more difficult than twenty years ago to contain the subject in a single volume and some parts get scant attention considering their recent growth Whether the parts briefly mentioned should have been omitted in favour of more detail on those in which the author is most authoritative, however, is a moot point, for in these days of increasingly narrow specialization it is certainly refreshing to find someone willing to look at the subject broadly, even though the looks in some directions may be only glances

Review journals are necessarily complements to standard texts They are better able to keep up with advances in the subject and they provide opportunities for specialists to present detail inappropriate in a general book The eight articles in volume 2 of "Advances in Pest Control Research" cover a wide range of subjects and some authors have undoubtedly made full use of the opportunity to be detailed Here the contents can only be indicated by summarizing the titles and naming the authors fluid kinetics of sprays (R P Fraser, 106 pp), toxicity of fungicides (S E A McCallan and L P Miller, 28 pp), seed and soil treatments with insecticides (H T Reynolds, 48 pp), the use of isotopes to measure spray residues (C T Redeman and R W Meikle, 24 pp), wool digestion and moth proofing (D F Waterhouse, 56 pp), the relation of chemical structure to herbicide activity (R L Wain, 44 pp), chemical structure and activity of DDT analogues (R Riemschneider, 44 pp), the spread of resistance to insecticides in pests (A W A Brown, 64 pp) It is to the credit of the authors that most have accepted the editor's invitation to evaluate their subjects critically and have not simply summarized published work

The other two books are for the grower of crops rather than the research worker "Recognition of Diseases and Pests of Farm Crops" is a most welcome and most unusual book The text consists simply of captions to the 112 magnificent colour plates containing more than 700 beautiful water-colour paintings by I Frederiksen and E Olsen The sole purpose is to aid diagnosis, which the book will do permanently and everywhere, and methods for controlling the pests and diseases so accurately portrayed are deliberately omitted because they often change and may differ in different countries The book by G. L Hey and K Marshall complements the work of art from Denmark and contrasts strikingly with it It is most valuable for its succinct recommendations for controlling specific pests and diseases, is least satisfactory for diagnosis, and its pictures are neither beautiful nor very helpful With both books, the farmer or gardener is well equipped to avoid much loss, and it is no mean testimonial to the achievements of plant pathologists that growers now have reliable methods to control so many pests and diseases

FREE RADICALS

Free Radicals as Studied by Electron Spin Resonance

By Dr D J E Ingram Pp ix+274 (London Butterworths Scientific Publications, New York Academic Press, Inc, 1958) 50*s* , 9 50 dollars

Free Radicals

An Introduction By A F. Trotman-Dickenson (Methuen's Monographs on Chemical Subjects) Pp viii+142 (London Methuen and Co, Ltd , New York John Wiley and Sons, Inc , 1959) 12*s* 6*d* net

MOST free atoms are associated with one or more unpaired electrons, and the formation of compounds generally involves the complete pairing of such electrons in molecular orbitals Nevertheless, many molecules, of widely varying degrees of structural complexity, have a single unpaired electron These bodies, known as monoradicals, comprise the most important group of free radicals, and it is with them that the greater part of both of these books is concerned

The unpaired electron confers two important properties on the monoradical In the first place the electron spin is associated with a magnetic moment, which may align itself in one of two ways with respect to an applied magnetic field Transitions between the energy-levels corresponding with these two alignments can be made to fall conveniently in the microwave region, giving the phenomenon known as electron spin resonance The transition will be associated with hyperfine structure resulting from the interaction of the electron spin with the various nuclear spins, if any, in the radical This hyperfine structure may then be used to 'locate' the electron within the molecule, and hence to obtain information about the orbital, and about the structure of the molecule In the second place, the presence of an unpaired spin within a molecule makes it more reactive, and free radicals often play important parts in chemical reactions, since their reactions can provide convenient paths by which the final products may be produced most easily Dr Ingram's book is concerned with the first of these aspects of free radical behaviour, and Dr Trotman-Dickenson's with the second, in particular with the elementary reactions of free radicals, while avoiding chain reactions and oxidation processes

The overlap between the books is very small, and it is a pity that they have effectively the same title, differing only in subtitle In both cases the contents are excellent, and may be recommended to all workers in the field of free radicals

Dr. Ingram's work falls into two main sections, the first being concerned with the techniques of electron resonance, and with those parts of the theoretical background necessary for the interpretation of the spectra of free radicals. The 'experimental' part will be a most valuable guide to those contemplating work in this field, to many of whom microwave methods will be unfamiliar. The various types of spectrometer are clearly explained, and their relative merits discussed; the appendix, dealing with sources of equipment, is a worthwhile addition. A pleasing account of the sources of hyperfine structure follows. The rest of the book is a sectionalized review, with useful explanations, of work up to the present. There are chapters on stable free radicals (mostly fairly elaborate organic molecules or ions), on 'trapped' radicals produced by irradiation of solids or materials in glasses, and on the radicals formed in the course of polymerization and of pyrolysis (of solids). All are interesting, and suggest future applications. Dr. Ingram's field defines itself well without the rather odd definition of a free radical which he gives (p. 2), in which reference is made to 'normal chemical bonding'; all free radicals are held together by normal chemical bonding.

The book by Trotman-Dickenson is, in effect, an extended and intelligently written review covering a field of chemistry with a much longer history. It is of great value in so far as it ignores the artificial boundaries which appear to have arisen in chemistry, and because of its systematized account and assessment of a very large amount of material. It is not the author's fault if the available matter for some of the sections is inconclusive. The book will prove useful to those connected in any way with this amorphous field.

Both books attempt short treatments of 'biradicals', from very different points of view. This topic holds much for the future. T. M. SUGDEN

THE IMPORTANCE OF NEW DETECTORS

Čerenkov Radiation and Its Applications

By Dr. J. V. Jelley. Pp. x+304. (London and New York: Pergamon Press, 1958.) 65s. net.

IT is seldom that the first book to appear on any topic is so thorough as this work by Dr. Jelley. The treatment of the largely new subject of Čerenkov radiation is very complete in its scope and the many workers in the field, whether they are engaged in fundamental studies of this form of radiation or in some relatively straightforward application of a tool based on the phenomenon, owe a debt of gratitude to the author for this comprehensive study. Those who heard the evening discourse by Academician Tamm at Geneva in 1958 were given a clear picture of the rather intriguing history of the subject and the relatively sudden introduction of practical detectors, based on the Čerenkov effect, seemed the more surprising.

Jelley has gleaned his material from many rather scattered sources and presented it here in a well-integrated form. The rather extensive theory is well supported by his clear expositions of the experimental work in the field and in this he shows the skill of one who has personally made considerable contributions to the subject. The author makes it obvious that the subject is likely to produce more surprises in the future and those interested will find much to stimulate their thought in this volume. Many fruitful researches can be expected in this field and Jelley himself indicates some of these. Modern physics perhaps owes its rapid progress more to the introduction of novel detectors than to any other successes. We need but mention the Geiger and proportional counters, the Wilson cloud-chamber, the nuclear emulsion-plate, the scintillation counter, the Čerenkov detector and the bubble chamber to realize the fundamental nature of the contribution that stems from the study and perfection of these devices. Moreover, their value extends to many fields beyond that of pure physics.

The volume can be very highly commended as a most readable, careful and thoroughly up-to-date account of the subject.

THE VERY COLD WORLD

Experimental Techniques in Low-Temperature Physics

By Guy Kendall White. (Monographs on the Physics and Chemistry of Materials.) Pp. viii+328. (Oxford: Clarendon Press; London: Oxford University Press, 1959.) 45s. net.

ABOUT a quarter of a century ago, all low-temperature physicists (and there were not many of them) knew each other, and picked each others' brains fairly regularly, so that the dissemination of cryogenic techniques was rapid and satisfactory. To-day, however, when every well-equipped physics laboratory has or should have its cryogenic facility, the older method of communication is no longer adequate. Many physicists all over the world now want to be able to handle cryogenic liquids safely and efficiently; hence the timely appearance of this useful book on cryogenics, the first for nearly twenty years and the first in the English language.

A wholly satisfactory book on techniques is a difficult thing to achieve, probably because a technique is part of a craft and the communication of a craft is not easily done by the printed word. In spite of this difficulty, here is a book which will be of very great assistance to new hands at the low-temperature game, and of not inconsiderable value to the old hands as well. An especially good feature is the 'feel' it gives for cryogenic physics, which will be appreciated by its practitioners.

There are faults, of course. The book strays too frequently into theory. No one is seriously going to read this book to find out how electron spins align themselves in an external magnetic field, or to study the formal derivation of the absolute thermodynamic scale of temperatures. But there are excellent chapters on heat exchangers and their calculation, on mechanical thermal contact, and on thermometry. The important methods of cryostat temperature control are well described, although it would have been valuable to have included some of the electronic circuit diagrams with magnitudes of quantities to give any desired sensitivity of control.

The chapter on vacuum techniques, soldering and sealing is good so far as it goes, but there is no mention of how to make a soft soldered joint that (*a*) will be mechanically strong, (*b*) will never leak, and (*c*) can be non-destructively unsoldered. Further, there is no mention of leak-hunting, that grimmest of pursuits, or of real or virtual leaks, or indeed of whether or not the author personally believes in such things as low-temperature leaks The diagrams of actual apparatus are often too schematic to be of great use, for example, the transfer tube and valve on pages 53 and 55, of the design of both of which I disapprove There is a mention of the use of spontaneous oscillations as a means of liquid level indication, but no description of this odd phenomenon nor any warning of its often annoying and occasionally horrifying effects

All of those are, however, minor criticisms The book contains a mass of useful cryogenic information Generally it gives highly commendable critical comparisons of various experimental methods, such as those used in calorimetry, and for the first time collects really valuable critical data on emissivities and on total thermal conduction and expansion coefficients between room temperature and 1° K

J F ALLEN

A BIOCHEMIST'S GUIDE TO THE NERVOUS SYSTEM

Biochemistry and the Central Nervous System

By Prof Henry McIlwain Second edition Pp vii+288 (London J and A Churchill, Ltd, 1959) 45s

IT is a considerable achievement for Prof McIlwain to have produced a second edition of his book (already translated into Spanish and Japanese) in such a relatively short time The need for a new edition is some indication of the rapid increase in our knowledge of the biochemistry of the nervous system to which the author and his colleagues at the Maudsley Hospital have made valuable contributions

The layout of this book follows the previous pattern though there have been extensive revisions and additions There is, for example, a new chapter, which is very much to the point, on the relation of the brain to the body as a whole, and the section on brain lipids has been considerably modified in the light of recent observations Knowledge of the metabolism and functions of proteins in the brain is still somewhat limited, but until Table 6, on the chemical nature and diversity of brain proteins, can be extended it is likely that progress on this particular aspect will be slow I was again impressed by details given about the rates of chemical reactions in brain and their relation to the speed of cerebral processes, information which is becoming more valuable as it becomes more extensive

Much useful information is summarized in diagrams and tables (Fig 34 and Table 28 are instances of this) It is perhaps significant that one of the column headings in Tables 8 and 9 has been changed from "acid-labile phosphate of adenosine triphosphate" to "acid-labile phosphate of purine nucleotides" in the second edition, thus indicating that the free nucleotide content of cerebral tissues is more complex than had previously been indicated

The chapter on chemical factors in nervous transmission is an extremely able résumé of a mass of information, and some indication of the speed at which this subject is developing can be deduced from the fact that references to the possible role of γ-aminobutyric acid as a pharmacologically active agent are all dated 1955 or later Biochemical aspects of the action of depressants and excitants receive their due, and in view of the current multiplication of drugs this summary is of some considerable value Perhaps the one surprising omission in the book is an appraisal of the extensive work of Geiger and his colleagues on the metabolism of the isolated, perfused brain *in situ*

Elsewhere the author of this volume has remarked, "Until the central problems of neurochemistry have been successfully tackled and we see more clearly how the nervous system utilizes its large energy supply in nervous transmission and in maintaining the system in a state of readiness to react, and how the brain is moulded to an animal's experience, chemical aspects of most of the neurological sciences—and above all, material approaches to nervous, mental and emotional diseases—remain as empirical as was organic chemistry before the advent of structural formulæ" If this book promotes further studies on this intriguing but complex subject then we shall all have been well served Indeed, it can be recommended to anyone who wishes to learn something of the biochemical processes underlying nervous activity and the relevance of these processes to a study of mental diseases A comprehensive bibliography at the end of each chapter and, for a book of its size, a monumental index, make it an extremely useful handbook in a field where suitable handmaidens are hard to come by

G B ANSELL

FAUNA OF NETHERLANDS NEW GUINEA

The Animal World of Netherlands New Guinea

By Dr L D Brongersma Pp 71 (Groningen J B Wolters, 1958) n p

THE island of New Guinea remains little known to the majority even to-day, and its fauna has received little attention through television or in popular published work It is one of the remaining major areas in which new zoological discoveries are likely to be made and is a region as yet little touched by commercial development Its animals, despite their affinities with Australia, are unique and much work remains to be done before they are fully surveyed Geographically, the island and its outliers form the most western extension of the Sahul shelf, and the study of the fauna is vital to the zoogeography of Australasia For these reasons the publication of a semi-popular account of the fauna of New Guinea is both timely and welcome Dr L D Brongersma has produced an interesting and factual book, based on his radio talks on the subject Written for the layman, the book is concerned with the novel and unusual, but also contains much of interest to the specialist Notable peculiarities among mammals, birds reptiles, amphibians, fish and crustaceans are described, with notes on their habits, ecology, economic value and sometimes history The text is enlivened by field observations, line drawings and photographs The author stresses the need for nature conservation in New Guinea, with emphasis on the dangers of uncontrolled commercial development and ill-considered introduction A short chapter and a map of the Sunda and Sahul shelves give a background to the origin of the fauna, and the book concludes with a useful account of the zoological exploration of New Guinea The author, whose aim was to encourage interest in the fauna of New Guinea and its conservation, has written a thoroughly readable account of the novelties and notable animals of the island

J E HILL

Mineralogy and Geology of Radioactive Raw Materials

By Prof E Wm Heinrich Pp xiv+654 (London McGraw-Hill Publishing Company, Ltd , 1958) 112*s* 6*d*

IN recent years more geologists have been engaged in explorations for radioactive ores than in any other hard-rock phase of the mineral industry, and since the lifting of security restrictions many thousands of research papers on radiogeology have seen the light of day Prof Heinrich has set himself the task of evaluating and summarizing this vast literature, and the result of his labours is the most outstanding monograph on uranium and thorium mineralization that has yet appeared in any language The work begins with approximately 150 pages on systematic mineralogy, continues for 400 pages with a lucid and descriptive classification of the world's radioactive ore deposits, and ends with 100 pages of bibliography (1,000 items) and comprehensive indexes Not all his views are uncontroversial for example, the designation of the Witwatersrand and Blind River ore-fields as respectively mesothermal and hypothermal epigenetic mineralizations will find little acceptance in the placerist schools of South Africa and Germany But all geologists concerned with the radioactive elements, academic workers and prospectors alike, will find interest and inspiration in these pages Nearly all the 200 text-figures are new to text-book literature Some minor errors in place-names, in the failure to recognize synonymous localities (for example, Kasolo and Shinkolobwe) and in the consistent mis-spelling of the mineral names thucholite and parsonsite should be corrected in the second edition, which will doubtless be required as soon as the present glut of uranium is taken up by industry and geologists are once again called on to find new ore fields

C F DAVIDSON

Substitution at Elements other than Carbon

By C K Ingold (The Fifth Weizmann Memorial Lecture Series, May 1958) Pp viii+52 (Jerusalem The Weizmann Science Press of Israel, 1959 Distributed by the Weizmann Institute of Science, Rehovot) n p

THIS little book is a record of four lectures and is divided into two chapters The first of these discusses substitution in some co-ordination compounds, principally derivatives of cobalt (III) Attention is directed to the stereochemical course of substitution by the unimolecular and bimolecular mechanisms, and to the particular problems associated with group replacements in molecules of octahedral symmetry An appendix is also provided to support further the theory of a direct S_N2 mechanism

The second chapter is concerned with nitration and nitrosation at nitrogen and oxygen atoms There is much more evidence available in this field and the author has surveyed it lucidly and succinctly The various reagents and mechanistic ambiguities are well set out and some ingenious experiments which exclude many of these alternatives are carefully detailed

The work is clearly printed and the diagrams are well produced There is no index, but a generous bibliography at the end of each chapter which is of greater value in a book of this length The only error I noticed is the omission of the minus sign from NO_3^- in the last relevant equation on page 32

This book is valuable both as a summary of the present position in this rather neglected study and for the outlining "of a mechanistic pattern", to quote the author's own words In his preface Sir Christopher suggests that prospects are extensive, and I feel that the analysis given in this work signposts the way well into a largely uncharted region

R I REED

Contact Catalysis

By Dr R H Griffith and J D F Marsh Pp x+300 (London Oxford University Press, 1957) 50*s* net

IN these days of many-volume treatises on catalysis, the smaller book also has its place , and the publication of a third edition of Dr Griffith's well-known text-book on contact catalysis, now written with the collaboration of J D F Marsh, is both timely and welcome It continues to give a condensed and well-planned survey of many of the more important classes of reactions involved in heterogeneous catalysis, together with an adequate treatment of the underlying theory

In order to accommodate, in a condensed form, the large amount of additional material which has resulted from the intense study which this subject is receiving, three new chapters have been added These deal, respectively, with modern practice in the preparation and empirical evaluation of stable catalysts having a high specific surface, with the part played by electronic factors in determining the catalytic activity of metals, and with a number of reactions involving hydrocarbons There has also been considerable rearrangement of the older sections of the book, and much of the descriptive matter on the promotion of catalysts by small amounts of subsidiary components and on the poisoning of catalysts has been revised and brought up to date This applies also to the chapter on the part played by geometrical factors, and especially by interatomic distances, in accommodating without undue strain the reactive portions of catalysable substrates The volume ends with a critical survey of modern progress in catalysis, with some forecasting of possible future developments This book continues to form an excellent summary of modern trends in catalysis

Practical Animal Ecology

By W H Dowdeswell Pp 316+16 plates (London Methuen and Co , Ltd , 1959) 32*s* 6*d* net

IN many British schools and universities lip-service is paid to the importance of field studies in zoology, whereas the actual practical effort is often limited to a few days at a field study centre or attendance at a single Easter-course in marine biology

Here, almost for the first time, is a book which will really assist teachers and lecturers to introduce their students to modern animal ecology The book lives up to its title A wide range of methods and techniques is described which are applicable to the study of terrestrial, freshwater, marine and brackish water habitats In some cases guidance is given on the construction of what would otherwise be expensive pieces of apparatus To get the best out of this book, the student should be given considerable help by his teacher So much is packed into it that many students let loose with it will suffer ecological indigestion

On modern standards the price is reasonable, for in my opinion this book should have a major effect on the teaching of animal ecology in schools

J B CRAGG

THE FIRST MINISTER FOR SCIENCE

By the Right Hon. VISCOUNT HAILSHAM, Q.C., LORD PRIVY SEAL AND MINISTER FOR SCIENCE

THE proposal for a Minister for Science was first talked about when the Conservative Manifesto was being prepared. I was myself at first very sceptical. It seemed to me that there were two very great pitfalls to be avoided. On one hand there was the danger that the scientific world—the Royal Society, the universities, the industrial scientists, the Atomic Energy Authority and the Research Councils—the Department of Scientific and Industrial Research, Medical Research Council and Agricultural Research Council, Overseas Research Council and Nature Conservancy (the governing boards of which are very largely manned by volunteers)—would think that too much was intended, and that the new Minister would interfere with the independence and integrity of the scientist in his own sphere. If that danger were not avoided, I feel that I should lose the confidence of those on whom all else depends and whose co-operation I must win if I am to succeed at all. I hope and believe my appointment has allayed these fears. After all I am the same man who has been Lord President of the Council for the past two years. My general attitude to science and scientists has been made plain to those who were interested, and I believe has won confidence. No change in that general attitude is involved in the new appointment. I have no authority over the universities to compel them to do anything they do not wish to do. My authority over the Atomic Energy Authority and the Research Councils is no greater than my predecessors and I had before, and I have no intention of taking away from them the authority which Parliament has given to them, or the freedom which they now enjoy to perform their functions without detailed interference. I am there to give them general guidance and to help them in their relations with Government, especially other Government departments.

But an equal and opposite danger is to be expected at this point. I can almost hear the cynical comment: "New Presbyter is but Old Priest writ large. The Manifesto promise, the new Minister, is just a piece of political window dressing. Nothing more is to be expected and everything will go on exactly as it was before." I hope and believe this is a mistake, and I would not have accepted the appointment had I believed otherwise.

All the same, I would like to make it plain at the outset that this is a long-range project. You must not expect clutches of satellites to be flung into orbit in a miraculously short space of time. Sponsors of ingenious inventions will be disappointed. The Minister is not a repository of brilliant new thoughts which have failed to appeal to anyone else. He is not an overlord to the Minister of Education and will not therefore be able to create vast new academies of science and technology. He is not "Master of the Queen's Rockets" and will not therefore play a decisive part in the politics of guided missiles. He is not a super Minister of Power nor a Minister of Transport, Agriculture or Health. Indeed, I must emphasize that unless all the other Ministers in the Government—I think without exception—are at least as scientifically minded as I ought to be myself, my work will be frustrated—and until they are my work will be incomplete. I do not think it is necessarily a disadvantage that I am not a professional scientist. The First Lord of the Admiralty is not a naval officer; the Minister of Transport would not necessarily be better for being a railway man. In the main, parliamentary government is government by amateurs advised by experts. The one exception is the Lord Chancellor, and he has a technical legal job to do. In my own case I believe that the appointment of a non-scientist as the first Minister will compel scientists to do the most urgent thing, that is, to share in the thought about scientific policy themselves.

For, whether or not there is need for a Minister or a Ministry, two years experience as Lord President has convinced me that there is need for a policy for science and that policy cannot be the product of Government thinking alone.

In describing my task I will start by one or two general propositions. Science in Great Britain increasingly touches life at every point. It is thus necessarily a partnership—and, since Britain is a democracy, it is necessarily a partnership in which everyone is invited to play a part. But the indispensable partners are industry, agriculture, medicine, teaching, the universities and Government—and, of course, both the scientists and the non-scientists who play their part in the administration of the various branches of public and economic life. In all these spheres my task is to promote science. But only in part of one of these spheres of activity—that of Government—have I the power to achieve this by the use of authority as distinct from encouragement, diplomacy, enthusiasm, example, precept or advice.

Secondly, after two years as Lord President of the Council, I would say that, if only because of the very multiplicity of scientific disciplines, Government science, and perhaps all British science, is at the moment too parochially minded, too departmentalized and lacking in the broader vision. The Research Councils and the Atomic Energy Authority are by their very terms of reference limited in their spheres.

However, a Minister for Science is bound to look for a more generalized philosophy and approach if he is to succeed. In some ways the focus of scientific opinion in Great Britain is the Royal Society. Long may it flourish. But for the purpose of advising the Government on scientific policy, the proper channel already exists in the form of the Advisory Council on Scientific Policy. I believe that this body provides one of the keys to the present situation, composed as it is of a unique connexion of Government and non-Government scientists under an independent chairman with a vice-chairman who happens also to be the chairman of the Defence Research Policy Committee. I shall endeavour to rely more than ever upon this Advisory Council for generalized advice on questions of scientific policy My purpose is to make the voice of science coherent and articulate under Government encouragement, and in one real sense to make science self-governing under Government inspiration For this purpose a greater use of the Advisory Council on Scientific Policy is inevitable I had already begun to move in this direction in the last Parliament I hope to go further now, and I feel I am going to be helped by the more flexible and numerous office staff (which supplies the secretariat of the Advisory Council) with which I shall be equipped as the result of the marriage between the Atomic Energy Office and the Lord President's Office Thus assisted I shall try to tackle such questions as whether the general balance of scientific effort is right or could be better deployed, and other questions of a general nature as they emerge Already in the last Parliament I had pressed forward an inquiry under the late Sir Claude Gibb (now chaired by Sir Solly Zuckerman) on techniques of management and control of Government financed research and development, and I look forward to a report from them, with positive suggestions, when they have completed their heavy task

One of the matters I referred to the Advisory Council on Scientific Policy in the last Parliament was the question of space research, and it was as a result of its advice that the Steering Group under Sir Edward Bullard was set up and the group of scientists under Prof H S W Massey paid their recent and successful visit to the United States I am not sure that either the philosophy or scope of our policy on space research is yet fully understood, and I would welcome the opportunity of expounding it more fully should questions be directed to me

I also have great hopes of the Overseas Research Council which I set up at the end of the last Parliament under the chairmanship of Dr R S Aitken The object of this body is to act as a sort of clearing-house for our research effort overseas both separately and in co-operation with other countries

I also hope to show a personal interest in the applied research which is very widely carried out by private industry and in industrial research associations under the general authority of the Department of Scientific and Industrial Research But execution of all this work will continue to rest with the bodies entrusted by Parliament with those functions

In many ways the clue to the picture of science in Britain lies with the universities—especially with those which have great potentialities for growth and indeed an increase in numbers To explore this in any detail would be outside my present purpose and indeed outside my function as the Minister for Science I have no authority over the universities nor over the University Grants Committee, and I have no ambitions to obtain such authority But I shall try to forge friendly links with both, both personally through individual contacts, and by discussions between officials In particular, I have ideas for the forging of closer links between the Government research stations and institutes, and the universities, from which I believe both the Government stations (and the scientists who work there) and the universities would stand to gain in prestige and in effectiveness

I also believe that the time has come for the purse strings of private munificence by industries and industrialists to be opened again for the benefit of universities and colleges and I will do all in my power to produce interest in this My object here is not to limit the amount of Government help, but to widen the front of public interest, and increase academic independence and flexibility It would be ungenerous and at this time insensitive not to point in this connexion to the gifts rightly described as princely—including one particularly welcome from the Transport and General Workers' Union, to Churchill College and to the project for St Catherine's reconstitution at Oxford But, greatly daring, may I say that I do not see why gifts from individuals and institutions should be concentrated on Oxford and Cambridge or even London ? The greatest scope for enlargement and improvement surely lies elsewhere, as other generous and far-sighted benefactors have recognized

The teaching of science and mathematics in the schools is again not a matter for me but for the teaching profession, and my contact with that profession must be through the Minister of Education , but I hope to keep a close liaison with the Minister in this and other matters, and I shall also try to seek guidance from the representatives of independent schools

It is clear, I think, that in a single term of office only the foundation can be laid of a genuinely scientific approach to the problems of the present day I hope that my ambitions in this direction will not be despised as inadequate because they are realistic and long-term My hope will be to engender in all a genuine enthusiasm for science, and respect for scientific work and scientists , not merely for their practical achievements, but also for the cultural values they represent If I win their confidence, and also make clear to the public and to my colleagues the nature of their needs and their outlook, I will not have failed Above all, I would like to say that I bring to this new and creative work all the enthusiasm and desire to serve of which I am capable, and a real determination to see that British science continues to be an instrument of peaceful progress and a means of enhancing British prestige in the world and British prosperity and culture

ROCKET PROPULSION

AT the meeting of the British Association in York, one of the sessions in Section B (Chemistry), on September 8, was devoted to a series of papers and discussions about various aspects of rocket propulsion

The subject was introduced by Dr W B Littler, director-general of Scientific Research (Munitions), Ministry of Supply, who outlined the history of rocket development He referred to the early use of gunpowder for rocket propulsion and the introduction in the Second World War of a variety of rocket weapons made possible by the development of new solid and liquid propellants The German *V*2 rocket, with a range of 200 miles and a payload of 1 ton, was the outstanding technical triumph of its day Since the War, vast sums of money have been spent, particularly by the Americans and Russians, on all forms of missile research and development The all-up weight of some rockets has surpassed the 100-ton level, and a range of 5,000–6,000 miles is claimed for some ballistic missiles In relation to the resources and man-power employed, some impressive successes have been achieved in the United Kingdom, and important developments have been pioneered with solid and liquid propellants and with the motors associated with them

The index of propellant performance most frequently quoted is the 'specific impulse' The solid and liquid propellants now in common use have a specific impulse in the range 180–250, compared with the figure of only 60 for gunpowder Substantial increases in specific impulse are possible by the use of uncommon fuels and oxidants (for example, hydrogen and fluorine) but most military applications can be met by the use of conventional propellants, and these are adequate for putting artificial satellites into orbit The most spectacular advances in recent years have arisen from three developments (1) the substantial increases in the size of the rockets and the weight of propellant carried, (2) the perfection of the multi-stage rocket, whereby motors are discarded successively in flight, after all the propellant has been burnt, thus eliminating dead weight as quickly as possible, (3) the development of very large solid-propellant motors containing up to ten or more tons of propellant

Unlike liquid-propellant motors, the thrust of solid-propellant motors cannot yet be controlled in flight, but they are basically simpler for many applications and can be more easily maintained in a state of readiness As a result, their use has greatly extended in recent years, but there is a future role for both types of propellant For controlled flight in outer space, much higher performances, not attainable with chemical systems, are required

The first paper, "Thermodynamic Aspects of the Choice of Rocket Propellants", by Mr G K Adams, of the Explosives Research and Development Establishment, Waltham Abbey, discussed the relation between the thermodynamics of propellant ingredients and combustion products and the performance of rocket propulsion systems Applying the principle of conservation of momentum to a rocket in a force-free field, it can be shown that the velocity increment v is given by $v = \bar{V}\ln(M_1/M_2)$, where $\bar{V}$ is exhaust velocity of the combustion products, M_1 is initial mass of rocket, and M_2 is mass of rocket after all the propellant has burnt The exhaust velocity is used as an index of propellant performance It is generally quoted in the form of the 'specific impulse', which is the quotient of the exhaust velocity and the force-to-mass conversion factor, and has the dimensions of time

By applying the principle of conservation of energy, the square of the exhaust velocity can be shown to be proportional to the decrease in total enthalpy per unit mass on burning the propellant under rocket conditions It depends, therefore, on the initial chemical energy of the propellant and on the efficiency with which this is converted into translational energy in the exhaust jet

The demand for high chemical energy per unit mass suggests the choice of elements of low atomic weight, suitable oxidation-reduction reactions between these have energies in the range of 2–4 kcal /gm The energies of reactions between free atoms or radicals are much greater, but owing to their high reactivity even at extremely low temperatures, there appears to be little hope of utilizing them in propulsion systems Other factors in addition to those of energy must also be taken into account Thus a propellant must have adequate chemical stability, its physical properties must be suitable for the particular application, and the materials used in the construction of the combustion chamber must be able to stand up to the temperatures attained In practice, such factors tend to limit the range of useful chemical energies still further, and in these circumstances particular attention must be paid to achieving the most efficient conversion of chemical energy into translational energy of the rocket

The efficiency of the expansion process is governed by a number of considerations A low total heat capacity per unit volume of gaseous products is beneficial, this leads to a requirement that the gaseous products shall contain the minimum number of constituent atoms (for example, HF rather than H_2O), lower efficiencies result if solid products are formed Energy released by shifts in chemical equilibria during expansion can be used less efficiently than that released in the chamber Energy is lost through the non-attainment of velocity and thermal equilibria in systems giving solid products Chemical energy alone, therefore, is not an adequate criterion for the choice of propellant systems A change which increases the efficiency is often more useful than a mere increase in chemical energy Additional factors which have to be taken into account are cost and availability

Mr J E P Dunning, director of the Rocket Propulsion Establishment, Westcott, then spoke about "The Application of Liquid Propellants to Rockets" He referred to some of the more important ballistic equations and described the physical processes involved in a rocket engine using a liquid fuel (for example, kerosine) and a liquid oxidant (for example, oxygen) A steady pressure is maintained in the combustion chamber by feeding in the liquids at the same mass flow-rates as the gases are ejected from the nozzle The propellants are pumped into the head of the combustion chamber through a multiplicity of orifices designed to establish as quickly as possible a uniform mixture of fuel and oxidant Both liquids must be vaporized and this is brought about by atomization, initiated by the actual process of injection and accelerated by the combustion of preceding droplets Once established, the combustion process is self-supporting but has, however, many tendencies to instability Satisfactory geometry of the chamber and injection head is essential to reduce these irregularities to a minimum, but the nature of the problem is such that the empirical approach still has to be largely relied upon

In the case of a liquid oxygen/kerosine motor developing 100,000 lb thrust, it is necessary to feed liquid into the chamber at a rate of about 400 lb /sec, of which 280 lb /sec will be liquid oxygen and 120 lb /sec will be kerosine The injection head may have as many as 2,400 orifices each 0 1 in in diameter, from which the liquids emerge at about 100 ft /sec Within an axial distance of about 1 ft, and a time of 2–3 millisec, the physical processes of atomization, vaporization and chemical reaction have to take place In the combustion chamber the temperature attains 3,300° K and the pressure 500 lb /in ^{2}, and the gases emerge at a velocity of around 8,000 ft /sec The temperatures attained are such that the walls of the chamber and the nozzle have to be cooled, and either fuel or the oxidant is used for this purpose To feed the liquids into the injector head two turbo-pumps are used, since the alternative system of pressurizing the tanks is ruled out by considerations of weight The pumping power required is large, but is achieved with a propellant consumption of rather less than 2 per cent of that used in the combustion chamber

In selecting possible fuel/oxidant combinations, performance merits may be over-ridden by criteria such as toxicity, availability and cost A limit on overall performance may thus be imposed, but this can be countered by increasing the mass ratio (mass at launch/mass at 'all-burnt'), although with a single-stage rocket it is not practicable to exceed a ratio of about 14 to 1 Enhanced performance can then only be achieved by the use of multi-stage propulsion systems

Dr G H S Young, of the Explosives Research and Development Establishment, Waltham Abbey, then dealt with British solid propellants for rockets He pointed out that all solid propellants are explosives and, under appropriate conditions, can be detonated These conditions must be avoided during manufacture and use, and this consideration frequently limits what can be achieved practically

The two main solid propellants in use in Britain are extruded cordite, sometimes called double-base propellant, and plastic propellant The extruded cordites are similar chemically to gun propellants and are available in a wide range of sizes and burning-rates In general, the burning-rate is adjusted by altering the calorimetric level, the more energetic the composition, the faster it burns The size of charge which can be produced is limited by the size of the presses available and the hazards involved with large quantities However, the double-base system has been recently extended by the exploitation of a casting process in which the nitrocellulose is gelatinized in a mould by desensitized nitroglycerine, the charge then being cured at 140° F for some days In this way charges larger, and more complex in shape, than those capable of extrusion are being produced Both extruded cordite and cast double-base are used as loose charges in the rocket motors

Plastic propellant, however, being a putty-like material, is capable of case-bonding, since the material can accommodate the differential thermal expansion between the motor wall and the propellant itself This type of propellant has been developed to make use of ammonium perchlorate as the oxidizer Burning-rates are adjusted by the addition of ammonium picrate and, as with extruded cordite, the lower-energy compositions burn more slowly than those of high energy This propellant has been successfully used in the largest British solid-propellant rocket to date, namely, that used in the *Skylark* in the International Geophysical Year experiments, this rocket has a charge of about 1,800 lb of propellant and is 17 in in external diameter

Another solid propellant being investigated is the so-called pressed charge, pioneered by Nobel Division of Imperial Chemical Industries, Ltd In this propellant the ingredients are consolidated to rock-like form by powerful presses Ammonium nitrate is the oxidizer, and propellants with low rates of burning, particularly suited for assisted take-off units and for gas generators, are produced

The present trend is for rockets to increase in size, and none of the propellants mentioned, with the possible exception of cast double-base, is altogether suitable for large missiles Work is therefore proceeding on other castable composite propellants based on synthetic rubbers and, of these, polyurethanes appear to have many advantages There is also a demand for higher performance and this can only be achieved by the introduction of novel ingredients, such as light metals, or new combustion systems which might, possibly, be based on fluorine compounds In addition, if solid propellants are to be used in the larger missiles, then methods of thrust control and thrust termination will need to be developed and the reliability of operation will have to be very high

Finally, Dr L R Shepherd, of the Atomic Energy Research Establishment, Harwell, and chairman of the British Inter-Planetary Society, spoke about propulsion for space travel The equation mentioned earlier represents an idealized condition and in the actual case of a rocket accelerating from the surface of the Earth the actual velocity may be 1,000–2,000 metres/sec less than the value predicted by this equation on account of atmospheric resistance and other effects For even the most modest excursion into space the limitations of conventional propellants demand the use of multi-stage rockets Using available chemical propulsion systems in staged rockets, it should be possible to put 20-ton payloads into orbit around the Earth or to deposit 1–2 tons of instruments on the Moon But for any more ambitious mission, propellant systems of much higher performance are required

Dr Shepherd considered that the difficulties involved in the application of reactions between free atoms or radicals (mentioned by Mr Adams) made it seem unlikely that these can be successfully applied to a practical propulsion system

Another possibility is the utilization of forbidden transitions between excited and ground states in the electron shells of certain atoms, for example, helium If the active material can be stored and its energy released in the thrust chamber of a rocket engine, the potential usefulness of a small single-stage vehicle is enormously extended It may be that the storage of active helium at low temperatures is more feasible than that of atomic hydrogen

Speculations on the application of nuclear power to rocket propulsion generally assume that the energy from a nuclear reactor can be transferred to a suitable working fluid, the optimum material being hydrogen This might be achieved by heating the working fluid in a thrust chamber and allowing it to expand through a nozzle in a manner similar to conventional practice Alternatively, the working fluid may be ionized and accelerated as a plasma in a magnetic field There are many formidable technical problems to be overcome before such nuclear systems can be developed

The use of electrical methods of propulsion has also been proposed This would involve an arc discharge to heat a working fluid and expand it through a nozzle, or, to avoid excessive temperatures, the electrical acceleration of a working medium It is generally assumed that this would be effected by ionizing the working fluid, extracting the positive ions, and accelerating them through an electrostatic field Alternatively, a fully ionized plasma may be accelerated in an electromagnetic pump

The working medium of such a system would probably be one of the alkali metals, possibly sodium At a temperature of 3,500° K and a pressure of 10^{-6} atmospheres, a sodium plasma is 95 per cent ionized, there should therefore be little difficulty in producing and maintaining such a plasma

It is known that a great deal of development work on novel propulsion systems is being carried out in the United States and presumably also in the U S S R

In the discussion, Prof M Stacey expressed interest in the possibility of using fluorine in propulsion systems The high toxicity of the combustion products was cited as a fundamental difficulty, and costs would also be high In reply to questions concerning the relative reliability of liquid- and solid-propellant motors, it was pointed out that there is very little information to support an absolute comparison A liquid-propellant motor, being more complex, might be expected to have a greater rate of failure, but the opinion of many British workers is that, given adequate attention in the research and development phases, the reliability of liquid-propellant motors should at least approach that of corresponding solid-propellant motors Questions were also raised regarding the role of solid 'cigarette burning' charges in view of the desire for high loading densities for propellants It was explained that the application of this type of charge to larger motors is limited by the need for high burning-rates and the additional insulation necessary to protect the motor wall which is exposed to the hot combustion products as burning proceeds These factors rob the 'cigarette burning' charge of its immediate attraction

W B LITTLER

DENSITY OF THE UPPER ATMOSPHERE FROM ANALYSIS OF SATELLITE ORBITS: FURTHER RESULTS

By D. G. KING-HELE
Royal Aircraft Establishment, Farnborough

IN an article on this topic in *Nature* some months ago[1], a new method of determining air density from the rate of contraction of satellite orbits was described and applied to the satellites launched during 1957 and 1958 In the present article the method has been refined by taking account of atmospheric rotation, and further results are given, utilizing the satellites of 1959, for heights between 180 km and 700 km The variation of density with latitude and season, and day-to-night changes, are also discussed

The rate of decrease of the orbital period of a satellite, which can readily be measured, depends on the integrated effect of air drag around the orbit The drag is greatest at perigee, and for a given satellite it is the air density at heights a little above that of perigee which chiefly controls the drag effects and which can best be estimated from the rate of change of period, $\mathrm{d}T/\mathrm{d}t$

Method of Analysis

It is assumed, first, that the drag D acting on a satellite of mean cross-sectional area S, moving with velocity v relative to the centre of the Earth, in air of density ρ, may be expressed in terms of a drag coefficient C_D as

$$D = \tfrac{1}{2}\rho v^2 FSC_D \qquad (1)$$

where SC_D may be taken as constant, and the factor F is included to allow for the fact that v differs from the velocity V of the satellite relative to the ambient air F, which is equal to $(V/v)^2$, may be taken as

$$F = \left(1 - \frac{r_p w}{v_p} \cos i\right)^2 \qquad (2)$$

where r is distance from the centre of the Earth, suffix p denotes perigee, w is angular velocity of the atmosphere (taken equal to that of the Earth) and i is inclination of orbit to equator For almost all the satellites so far launched, F has been between 0 9 and 1

The second assumption is that the density ρ at heights above that of perigee may be taken as varying exponentially with height y, so that

$$\rho = \rho_p \exp\{-(y - y_p)/H\} \qquad (3)$$

where H, which is approximately equal to the scale height, is taken as constant The value of H is not known accurately at heights above 180 km , but, if H^* is the best estimate of H, the density at a height $\tfrac{1}{2}H^*$ above perigee, ρ^*, can be expressed in terms of $\mathrm{d}T/\mathrm{d}t$ by the equation

$$\rho^* = -\frac{0\ 158}{\delta}\frac{\mathrm{d}T}{\mathrm{d}t}\sqrt{\frac{e}{aH^*}}\left\{1 - 2e - \frac{H^*}{8ae} + 0\left(e^2, \frac{H^2}{a^2e^2}\right)\right\} \qquad (4)$$

where $\delta = FSC_D/m$, m is the mass of the satellite, a is the semi-major axis and e the eccentricity of the orbit If $0\ 02 < e < 0\ 15$ and H^*, the best estimate of H, does not differ from the true value of H by a factor of more than 1 5, the maximum error in the expression (4) for ρ^* is less than 5 per cent If e is increased to 0 2, the maximum error is 10 per cent Equation 4 is the same as equation 5 of the previous article, except that SC_D/m has been replaced by FSC_D/m The introduction of the factor F allowing for atmospheric rotation changes the resulting values of density by 5–10 per cent, and the change is always an increase, since no satellite has yet (September 1959) been launched against the rotation of the Earth

When $e < 0\ 02$, equation 4 becomes less accurate, and for $0\ 005 < e < 0\ 02$, can best be replaced by

$$\rho^* = -\frac{0\ 0644}{\delta a}\frac{\mathrm{d}T}{\mathrm{d}t}\frac{\exp(ae/H^*)}{I_0(ae/H^*)}\left\{1 + 0(e) + 0\left(\frac{H}{a}\right)\right\} \qquad (5)$$

Table 1 VALUES OF $\delta = FSC_D/m$ FOR SATELLITES 1957α–1959ζ

Satellite		Mass m (kgm)	m/SC_D (kgm /sq m)	δ (sq m /kgm)
Sputnik 1	1957 α 2	83 6	110	0 0088
Sputnik 1 rocket	1957 α 1	—	63	0 015

Evaluation of δ

The main difficulty in applying equations 4 and 5 lies in the evaluation of δ ($= FSC_D/m$), and in particular of SC_D It is assumed here, as in the previous article, that each satellite rotated about its axis of maximum moment of inertia For satellites with length/diameter ratio greater than about 2, the extreme modes of rotation are then (*a*) travelling exactly like an aeroplane propeller, and (*b*) tumbling end over end In (*a*), the axis of spin and the direction of motion are in line , in (*b*), the angle between them is 90°, in practice, the angle may be anywhere between these extremes, and the mean of the values of SC_D for all modes of motion between (*a*) and (*b*) has been taken, the drag coefficient being calculated for free-molecule flow with diffuse reflexion

For near-cylindrical satellites, such as *Explorers* 1, 3 and 4 and *Atlas* (1958 α, γ, ε and ζ), SC_D has been taken as 1 85 λd, where λ and d are the effective length and diameter, the maximum possible error being 19 per cent A recent study[2] has shown that a rotating cone of length λ and base diameter d, and of shape similar to *Sputnik* 3 (1958 δ 2), has SC_D = 1 43 λd under mode of rotation (*a*), and 1 45 λd under mode (*b*), corresponding to drag coefficients (based on the appropriate mean cross-section) of 2 18 under mode (*a*) and 2 09 under mode (*b*) A drag coefficient C_D of 2 15 based on the mean of the cross-sections under modes (*a*) and (*b*) has been taken here For the spherical satellites, *Sputnik* 1 and *Vanguards* 1 and 2 (1957 α 2, 1958 β 2 and 1959 α 1), C_D has, as before, been taken as 2 2, based on the mean cross-section, including antennæ The values of δ for *Sputnik* 2 and the rockets of *Sputniks* 1 and 3 have been obtained by comparison with *Sputniks* 1 and 3, as explained previously[1] For the *Discoverer* satellites, which are cone-cylinders, δ has been taken as the mean of the cross-sections under modes (*a*) and (*b*), with C_D = 2 2

Table 1 lists the values of δ obtained for all the satellites launched before September 1959 whose orbits are known, except *Explorer* 6 (1959 δ), to which the theory is not applicable, since e is greater than 0 2 The values for the *Discoverers* apply during the period after the ejection of the re-entry capsule If the assumptions already stated are justified, the error (standard deviation) in the tabulated values of δ will probably be rather less than 10 per cent

Evaluation of Air Density

The air density at height $\frac{1}{2}H^*$ above perigee has been found for each of the satellites listed in Table 1 from equation 4 (or, for *Discoverer* 2, equation 5), the values of H^* chosen being consistent with those given later in this article For the Russian satellites, values of dT/dt, a and e have been taken from orbital

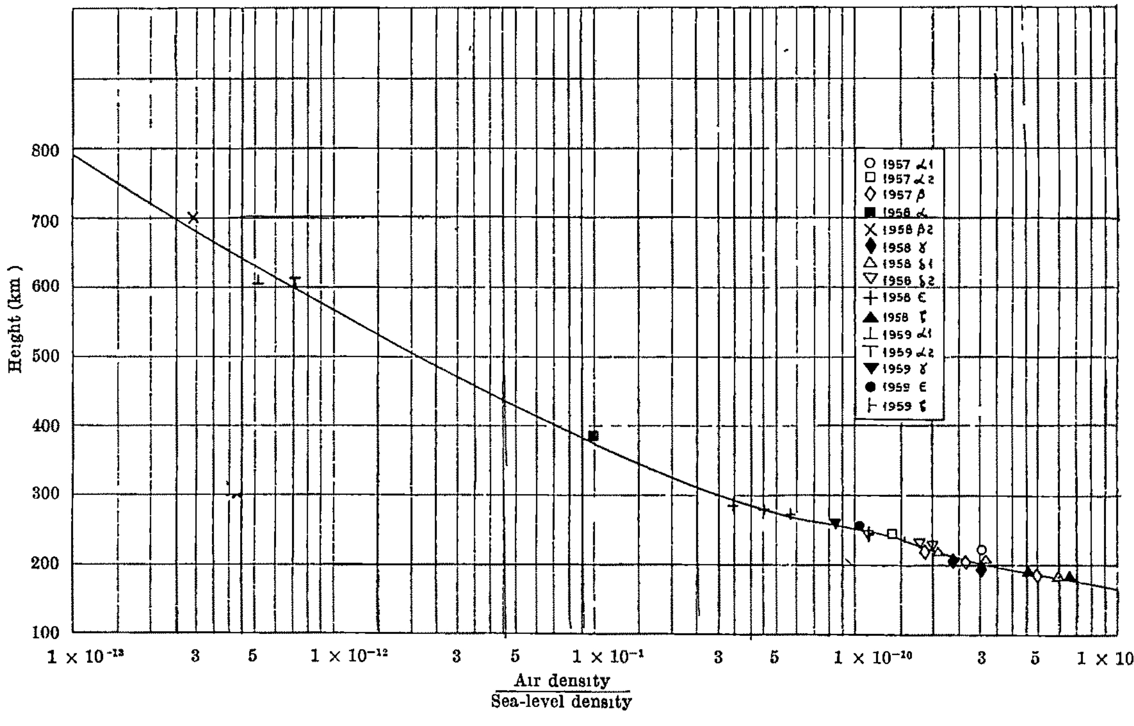

Fig 1 Air density obtained from satellites 1957α to 1959ζ

determinations made in Britain[3–6] For the U S satellites, values have come from the orbital data issued by the Smithsonian Astrophysical Observatory and by Project Space Track, Bedford, Mass For satellites with long life-times, the values of dT/dt have been averaged over intervals of several months

The resulting values of air density are shown in Fig 1, and a curve has been drawn through the points to represent average density It is worth noting that the individual points lie close to the curve, except for *Sputnik* 1 rocket, for which, however, the orbital information is rather meagre None of the other twenty points in the cluster below 300 km differs from the curve by a factor of more than 1 25 Some scatter is to be expected, because of the errors in δ and because the density varies from week to week by up to 30 per cent at 200 km height[7] and by 50 per cent or more at 700 km [8] Because of the latter variations, and because of the possible influence of charged drag[12,13], the three points above 500 km are less reliable than those below

The value of $6 7 \times 10^{-15}$ gm /c c for air density at 440 km , deduced[14] from the rate of expansion of a cloud of sodium vapour from the Russian Geophysical Rocket of February 1958, differs from the curve of Fig 1 by a factor of less than 1 25, and fills a gap in a rather empty region

Variation of Density with Latitude and Season

The points plotted in Fig 1 refer to latitudes ranging between 70° N and 50° S , and to all seasons , but there is no sign of any systematic variation of density with latitude or season In view of the small scatter, it seems probable that the density at a given height below 300 km does not depart from its average value by a factor of more than about 1 5 as a result of variations with latitude (between 70° N and 50° S) and with season This is in contrast with the direct measurements from rockets[15,16], which suggest a much wider variation, by a factor of 5 or even 10 , so it is worth seeking further evidence

Such evidence can be obtained from the orbit of *Sputnik* 3 between May 1958 and June 1959 During this time, the perigee latitude moved slowly from 50° N to 65° S , and the perigee height changed by less than 20 km The rate of change of period of *Sputnik* 3 thus provides a continuous indication of the air density at heights between 200 and 250 km , and over the range of latitude from 50° N to 65° S The air density ρ_p at the current perigee height was calculated from the equation[17]

$$\rho_p = -\frac{1}{3\delta}\frac{dT}{dt}\sqrt{\frac{2e}{\pi a H}}\left\{1 - 2e - \frac{H}{8ae}\right\} \qquad (6)$$

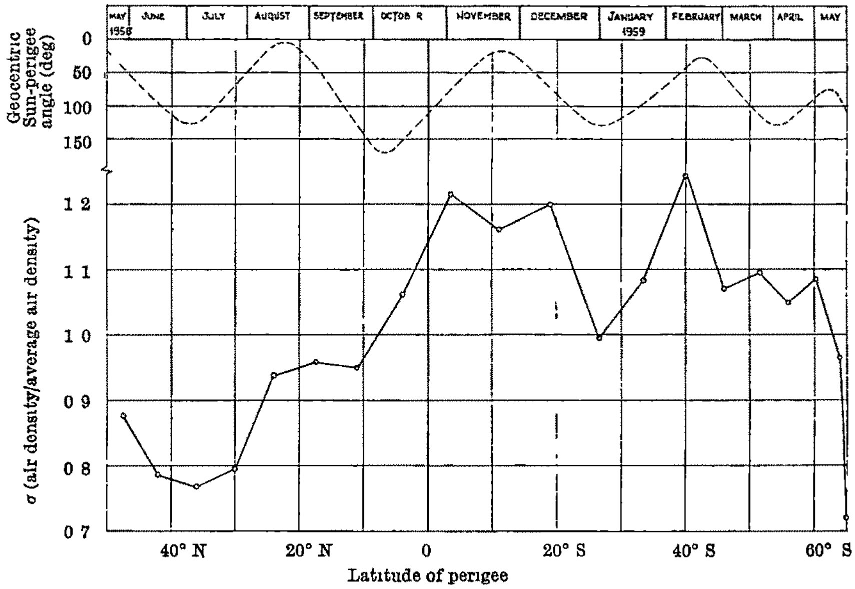

Fig 2 Air density at the initial perigee height of *Sputnik* 3, 226 km variation with latitude and time

with H = 30 nautical miles (56 km) The values of dT/dt were obtained from the records of orbital period kept by the Royal Aircraft Establishment (May–October 1958) and the Radio Research Station, Slough (October 1958–June 1959) The density at the initial perigee height y_{po} (226 km) was then found by multiplying ρ_p by $\exp\{-(y_{po} - y_p)/H\}$, where y_p is the current height of perigee over an oblate Earth This process gives the air density at the *initial* perigee height (226 km), but at latitudes near the *current* perigee latitude The resulting densities, calculated at 20-day intervals and expressed as a multiple σ of the average density, are plotted against perigee latitude in Fig 2 A satellite encounters drag over a range of latitudes near perigee, and each point in Fig 2 represents an average density over the 15–20° of latitude within which most of the drag effect occurs, rather than the density at the exact latitude where it is plotted Consequently, there is no virtue in reducing the time-interval between the points in Fig 2

The chief errors in σ are likely to result from errors in dT/dt (estimated standard error 3 per cent), H and $y_{po} - y_p$ (estimated bias errors 20 per cent each) and δ (maximum error[2] 5 per cent) The estimated standard errors in σ from these four sources are 3, 2½, 2½ and 2½ per cent, respectively, implying a standard error in σ of about 5 per cent

The density at heights of 200–250 km is known to vary with time, by a factor of up to 1 3, exhibiting a 28-day periodicity, which is attributed to solar disturbances[7–11], and one of the reasons for choosing a 20-day interval in Fig 2 was to avoid giving prominence to the 28-day oscillations Fig 2 represents the combined variation due to solar effects, latitude, season, etc Since none of the values of σ differs from 1 by a factor of more than 1 4, and the standard error is about 5 per cent, Fig 2 strongly suggests that the density does not depart from its average value, as a result of seasonal and latitude effects, by a factor of more than 1 5, between latitudes 50° N and 65° S , thus confirming the evidence of

Fig. 1, it is very unlikely that strong seasonal and latitude variations do occur and happen to have cancelled out for *Sputnik* 3.

It would probably be unwise to draw any positive conclusions about the variation of density with latitude and season from Fig. 2, but the large drop at the right-hand end does encourage the speculation that the air density at heights of 200–250 km. may be low at latitudes south of 60° S., at least in the winter.

Day-to-night Variations in Density

The upper curve in Fig. 2 shows the angle SCP subtended at the centre of the Earth (C) by the Sun (S) and the perigee (P) of *Sputnik* 3. If this angle exceeds 90°, the surface of the Earth below perigee is in darkness; if the angle exceeds about 105°, the perigee point itself is in darkness. Comparison of the two curves in Fig. 2, though inevitably inconclusive because of the errors in σ, gives the impression that the air density is related to the angle between Sun and perigee, a possibility which has previously been suggested by Sedov[18], Lidov[19], Groves[20] and others. If so, the air density at heights of 200–250 km. is rather higher on the sunlit half of the Earth than on the dark half, and this day-to-night variation, which had a period of about 90 days for *Sputnik* 3, and an amplitude of perhaps ± 10 per cent, would be superposed on the 28-day variation due to solar disturbances, which had an amplitude of about ± 20 per cent. A rather similar interpretation for a height of 700 km. was recently proposed by Wyatt[21], from analysis of the orbit of *Vanguard* 1, though at this greater height the angle between the Sun and perigee is, on Wyatt's interpretation, more important than solar disturbances. There is also some slight indication of a day-to-night variation for *Sputnik* 2 and *Sputnik* 3 rocket, though the 28-day variation is dominant[7,8,11].

Values of H

The slope of the density-versus-height curve of Fig. 1 gives the value of the coefficient H in equation 3, and Table 2 lists values of density and of H derived from the curve. Other curves, of different slopes, could however be drawn in Fig. 1; the individual values of H in Table 2 might, therefore, be in error by up to perhaps 20 per cent, though the mean value of H between 200 and 400 km. height is almost certainly between 50 and 60 km.

The rather irregular values of H in Table 2 between 200 and 260 km. result from the indentation in the curve of Fig. 1. If, instead, a smooth curve were drawn, seven successive points, from six satellites of quite different shape, size and date of launch (*Explorer* 4, *Discoverers* 2, 5 and 6, and *Sputniks* 1 and 3), would lie on the same side of the curve. The indentation, therefore, seems justifiable, though it might still be illusory, if several points happened to be in error in the same sense.

If the indentation is real, it indicates a rather large value of H—more than 50 km.—at heights near 220 km., in accord with the values of H found from the decrease in the perigee distance of satellites[1,22]. The air temperature depends[1] on the product of H and M, the mean molecular weight of the air. So, unless M varies widely between 210 and 230 km., the indentation corresponds to a peak in temperature near 220 km. height, the maximum value being near 60 M °K. The value of M is not known exactly, but is probably near 20. Such a peak in temperature might imply the absorption of certain wave-lengths in the solar radiation at heights near 220 km., though this deduction must be regarded as speculative[23].

Table 2. Values of Air Density and H given by the Curve of Fig. 1

Height (km.)	Air density / Sea-level density	Density (gm./c.c.)	H (km.)
180	6.4×10^{-10}	7.8×10^{-13}	27
200	3.2×10^{-10}	3.9×10^{-13}	35
220	2.0×10^{-10}	2.5×10^{-13}	52
240	1.4×10^{-10}	1.7×10^{-13}	46
260	7.7×10^{-11}	9.4×10^{-14}	32
280	4.5×10^{-11}	5.5×10^{-14}	47
300	3.0×10^{-11}	3.7×10^{-14}	57
320	2.1×10^{-11}	2.6×10^{-14}	62
340	1.6×10^{-11}	2.0×10^{-14}	68
360	1.2×10^{-11}	1.5×10^{-14}	75
380	9.3×10^{-12}	1.1×10^{-14}	77
400	7.2×10^{-12}	8.8×10^{-15}	79
500	2.1×10^{-12}	2.6×10^{-15}	86
600	7.1×10^{-13}	8.7×10^{-16}	90
700	2.5×10^{-13}	3.1×10^{-16}	99

Conclusions

A consistent picture of the air density at heights between 180 and 700 km. is obtained from the orbits of 15 satellites (see Fig. 1 and Table 2). The picture is more complete and more reliable at heights below 500 km. than above. All the results refer, however, to the years 1957–59, and it is probable that the density varies in the course of a sunspot cycle. There is some indication of a peak in temperature near 220 km. height, but there is no sign that density varies with latitude or season by a factor of more than 1.5. Analysis of the motion of *Sputnik* 3 confirms this latter conclusion, for a height of 220 km., and shows some evidence of day-to-night variation in density.

I wish to thank Mrs. D. M. C. Walker for preparing the diagrams and tables in this article.

NEWS and VIEWS

Nobel Prize for Chemistry for 1959

Prof Jaroslav Heyrovsky

PROF JAROSLAV HEYROVSKY, director of the Polarographic Research Institute of the Czechoslovak Academy of Sciences in Prague, has been awarded the Nobel Prize for Chemistry for 1959, for his discovery and development of polarography A native of Prague, he studied under Sir William Ramsay and F G Donnan in London before the First World War and then returned to Prague to continue his research work It is of interest that the work on the determination of the electrode potential of aluminium which led eventually to the development of the polarographic method was suggested to him by Donnan The first polarographic apparatus was made in 1925, but the method did not become widely recognized for a further decade, and Heyrovsky's major book, "Polarographie", did not appear until 1941 However, the number of papers dealing with polarography now approaches the 10,000 mark, and the technique finds application in many fields of chemistry and biochemistry , it has had a profound influence on analytical chemistry, for some determinations which are difficult or impossible to carry out by other means yield readily to polarographic treatment In addition, there have been made non-analytical applications For example, the kinetics of electrode reactions and of chemical reactions associated with redox processes have been studied, redox potentials have been determined and the energetics of the reduction of organic compounds have been elucidated Prof Heyrovsky has not enjoyed good health for some years, and is therefore prevented from accepting many of the invitations which he receives to lecture abroad The present award is a timely recognition of his great services to analytical chemistry, particularly as he will celebrate his seventieth anniversary next year

Glass Technology at Sheffield .

Mr Michael Parkin

WITH the retirement of Mr Michael Parkin, the Department of Glass Technology in the University of Sheffield lost its last member of that small team of pioneers recruited by Prof W E S Turner in the years immediately following the First World War to build up a department which has become world-famous Mr Parkin studied chemistry in the University of Sheffield , however, his studies were interrupted by war-time services in an explosives factory and in the Royal Flying Corps In 1920 he joined the Department of Glass Technology, and apart from a short period in industry (he was works chemist to Messrs Barr and Stroud, Ltd , 1924–28) he has served the Department continuously Until 1955 the Department performed dual functions, carrying out the work of a University department and advisory work and investigations for the industry under the advice of the Glass Delegacy, the members of which were roughly equally divided between the University and the glass industry Mr Parkin made a major contribution to this work This prevented his taking a direct personal responsibility for the research side of the work of the Department , but those whose responsibility it was to direct the research work would be the first to acknowledge the important part played by Mr Parkin in assisting research workers In 1955 the industrial work was taken over by the newly formed British Glass Industry Research Association, a step which Mr Parkin never pretended to approve, but, as all who know him would expect, he has, during these past four years, spared no effort to help the University Department in its new regime to flourish Perhaps the value which his present colleagues place on his services can best be emphasized by saying that he has been persuaded to continue as a part-time member of the staff for a short period while certain plans for future staffing of the Department mature

British Association Representatives in the U S.S.R

THE British Association for the Advancement of Science has accepted an invitation from the U S S R – Great Britain Society, conveyed through the Soviet Embassy in London, to send two representatives to the U S S R to visit schools, universities and scientific institutions, to meet Russian scientists and to discuss future relationships and exchanges The British Association's representatives are Dr W E Swinton, who is an honorary general secretary of the Association, and Sir George Allen, who is its secretary

European–American Nuclear Data Committee

A COMMITTEE for European–American Nuclear Data has been set up by the European Nuclear Energy Agency, in agreement with Euratom, the United States of America and Canada, to assure collaboration among members and associate countries of the Organization for European Economic Co-operation in the measurement of nuclear properties The Committee will be primarily concerned with measurements of nuclear cross-sections and other basic data essential for the technical development of nuclear energy The Committee is to consist of thirteen experts from the United States, Canada, the United Kingdom, the Euratom and other O E E C countries Its operations will be in accordance with existing bilateral agreements The work of the Committee will include the critical review of existing knowledge of nuclear cross-sections and constants, and of facilities, techniques and man-power available for their determination The Committee will also collect and correlate data from available sources, seek to establish a standard nomenclature and methods of presentation for such data, and recommend and sponsor, as necessary, technical meetings and symposia to further its objectives Finally, the Committee will promote the pooling and exchange, where appropriate, of equipment and personnel Further information can be obtained from the Organization for European Economic Co-operation, Château de la Muette, 2 rue André-Pascal, Paris XVI^e

New Forensic Science Society

A DECISION to form the Forensic Science Society was taken at a well-attended meeting held at the University of Nottingham on October 31 The object of the Society is to advance the study and application of forensic science in all its branches With this aim in view, a series of symposia, to be held alternately in London and in the provinces, is being arranged.

Among the subjects suggested for discussion are blood, hypoglycæmia, street accidents and instrumentation All persons professionally interested in forensic science are eligible for membership The president of the Society is Dr J B Firth, and the secretary Dr E G C Clarke, of the Royal Veterinary College, London, N W 1, from whom further information can be obtained

Preservation of the Malvern Hills

As a result of the confirmation, by the Minister of Housing and Local Government, Mr Henry Brooke, of an order made by the National Parks Commission under the National Parks and Access to the Countryside Act, 1949, about forty square miles of the countryside in the counties of Gloucester, Hereford and Worcester, including the whole of the Malvern Hills, are to be established as an 'area of outstanding natural beauty' The designated area extends from Knightwick in the north to Bromsberrow in the south and from Suckley, Cradley, Coddington, Wellington Heath and Ledbury in the west to Welland and Great Malvern in the east. It includes such well-known features as the Worcestershire Beacon, North Hill and the National Trust's property at Midsummer Hill The responsibility for preserving the landscape rests with the County Councils of Gloucestershire, Herefordshire and Worcestershire as the local planning authorities Government grants can be made at the rate of 75 per cent towards the cost of treating derelict land, tree planting and preservation and removing disfigurements Grants are also available towards expenditure incurred in making agreements or orders for public access to open country and in appointing wardens Designation does not provide any right of access to land not already open to the public Nor does it affect the existing use of land, such as the use of War Department land for military purposes

Newly Available Endocrine Preparations

THE Endocrinology Study Section of the National Institutes of Health has the following highly purified pituitary hormones available for distribution free to qualified investigators · growth hormone, bovine, non-sterile for animal experiments only, follicle-stimulating hormone, ovine, sterile preparation 25 mgm vials for experiment, 5 mgm vials for assay standard; luteinizing hormone, ovine, sterile preparation, 10 mgm vials, prolactin, ovine, sterile preparation, 25 mgm vials Further information can be gained from Dr R T Hill, Executive Secretary, Endocrinology Study Section, Division of Research Grants, National Institutes of Health, Bethesda 14, Maryland

National Science Foundation: Grants for Private Foundations in 1957

GRANTS made by the National Science Foundation for scientific research and development by private philanthropic foundations and voluntary health agencies totalled 95 million dollars during 1957, of which about 59 million dollars was in support of basic research (No 15, Reviews of Data on Research and Development National Science Foundation, Washington, D C) It is estimated that research expenditure for 1957 by private foundations and health agencies in the United States amounted to about 8 per cent of the estimated national basic research expenditure of 700–800 million dollars Expenditures for research and development by these institutions amounted to less than 1 per cent of the total expenditures for research and development by all organizations Of 4,067 private foundations surveyed, 438 reported research and development programmes, and a total expenditure of 72 million dollars Twelve foundations accounted for more than half this expenditure 82 per cent was in the form of grants and related administrative expenses to outside organizations The latter were predominantly educational institutions and their affiliated professional schools and hospitals One in five foundations with research and development programmes reported expenditure for research in their own laboratories or facilities The major part of support by foundations in 1957 covered the life sciences, accounting for 45 per cent of their total research and development expenditures The social sciences were next in volume of support, and the physical sciences last, according to the report Twenty-five of the thirty voluntary health agencies surveyed for 1957 reported expenditure for research and development, this amounted to 23 million dollars, of which almost one-half was for basic research. Four of the health agencies accounted for more than four-fifths of the total research expenditures, most of which were in the form of grants to outside organizations and individuals Educational institutions and affiliated medical schools and hospitals were the major recipients The voluntary health agencies concentrated almost exclusively on the support of biological and medical research.

Illuminating Engineering Society

AT the meeting of the Illuminating Engineering Society held in London on October 13, Mr H G Campbell was installed as president of the Society for 1959–60 Educated at Oundle and Queens' College, Cambridge, Mr Campbell is managing director of Benjamin Electric, Ltd, and a director of Holophane, Ltd The Leon Gaster memorial premium of the Illuminating Engineering Society for 1959 has been awarded to Dr R G Hopkinson and Mr J. Longmore (both of whom are with the Building Research Station of the Department of Scientific and Industrial Research) for their paper entitled "The Permanent Supplementary Artificial Lighting of Interiors".

U S. Society of Protozoologists

THE following officers, for the academic year 1959–60, were elected or appointed at the annual meeting of the Society at Pennsylvania State University, during August–September *President,* Dr Norman D Levine (University of Illinois), *Vice-President,* Dr. Reginald D Manwell (Syracuse University), *Executive Committee* (*new members*), Dr E R Noble (Santa Barbara College, California), Dr Charles Ray, jun (Emory University)

Mond Nickel Fellowships

THE Mond Nickel Fellowships Committee announced recently the award of a Fellowship for 1959 to Mr D J O Mann (John Lysaght's Scunthorpe Works, Ltd), to study the practical applications of recent metallurgical research and techniques to the production of basic semi-finished steel, and Mr. N J B Pocock (Capper Pass and Son, Ltd), to study developments in extractive metallurgy in the United Kingdom, Europe, the United States and Canada, and their dependence on the size and location of the organizations concerned

University News:

Hull

The Department of Scientific and Industrial Research has made a grant of £6,000 to the Department of Chemistry towards the purchase of a mass spectrometer in support of research by Dr G C Bond

The Nature Conservancy has made a grant of £4,900 to the Department of Geography for a three-year investigation into the coastal geomorphology of Holderness and Spurn Head

The following appointments to lectureships were made and took effect as from October 1 F J Bryant (physics) and I C Williams (zoology)

London

The following titles are announced that of professor of physics in the University of London, conferred on Dr M Blackman, in respect of his post at the Imperial College of Science and Technology, of professor of physical chemistry in the University of London, conferred on Dr F C Tompkins, in respect of his post at the Imperial College of Science and Technology, of reader in biochemistry in the University of London, conferred on Mr S P Datta, in respect of his post at University College, of reader in applied mathematics in the University of London, conferred on Dr C W Kilmister, in respect of his post at King's College

Oxford

Research grants are announced as follow · by the Medical Research Council, a grant not exceeding £1,100, for one year as from October 1, for scientific assistance in a study by X-ray analytical methods of insulin and related structures, to be carried out in the Laboratory of Chemical Crystallography under the direction of D M Hodgkin, reader in X-ray crystallography, by the United Kingdom Atomic Energy Authority, a grant not exceeding £5,700 for three years as from October 1, 1959, for studies in interferometric spectroscopy, to be carried out in the Clarendon Laboratory under the direction of H G Kuhn, also a further grant not exceeding £1,250 during the period October 1, 1959, to September 30, 1960, for work on the constitution of bismuth-rich alloys, being carried out in the Department of Metallurgy under the direction of Prof W Hume-Rothery, by the U S Public Health Service, a sum of 14,160 dollars for one year from September 1, 1959, for the continuation of research on vision and light quanta being carried out in the Department of Physiology by M H Pirenne, under the direction of Prof E G T Liddell

The Department of Scientific and Industrial Research has provided grants not exceeding £1,000 for one year as from October 1, 1959, for research on some natural products with biological activity, to be carried out in the Sir William Dunn School of Pathology under the direction of Dr E P Abraham, £1,500 for one year as from October 1, 1959, for research into perceptual limitations in high-speed performance in the Institute of Experimental Psychology by H Kay, under the direction of Prof R C Oldfield, £22,860 for three years ending September 30, 1962, for an investigation of the geological age of rock series by methods based on natural radioactivity, being carried out in the Department of Geology under the direction of Prof L R Wager, £1,220 for equipment for research on the biochemical mechanism of cell division, to be carried out in the Department of Biochemistry under the direction of Sir Hans Krebs, and £25,725 for the period October 1, 1959, to July 31, 1962, for an investigation of materials, using magnetic resonance and double resonance techniques, to be carried out in the Clarendon Laboratory under the direction of Prof. B Bleaney

The Admiralty has supplied, for the year ending March 31, 1960, a grant not exceeding £9,534 10*s* 0*d*, for the continuation of research on centimetre waves and fundamental problems being carried out in the Clarendon Laboratory under the direction of Prof B Bleaney, and the Ministry of Supply a grant not exceeding £1,175 for a year from September 1, 1959, for the continuation of an investigation of fluorocarbohydrates being carried out in the Department of Biochemistry under the direction of Dr P W Kent

Announcements

Mr F C Braby, chairman and managing director of Fredk Braby and Co, Ltd, has been elected chairman of the Council of the British Non-Ferrous Metals Research Association in succession to Dr Maurice Cook, who retires from that office on December 31

The Infra-Red Development Co, Ltd, Welwyn Garden City, has amalgamated with Hilger and Watts, Ltd, 98 St Pancras Way, Camden Road, London, N W 1 The Infra-Red Development Co was founded in 1946 and specializes in the analysis of gases by non-dispersive infra-red techniques, primarily for industrial purposes, it has been under the technical control and management of Mr W. B Bartley, who will remain managing director It will continue to operate at its works and offices in Welwyn Garden City

The well-known instrument makers, Griffin and George, Ltd, Ealing Road, Alperton, Wembley, Middlesex, are opening a new branch at 626 Welbeck Road, Walker, Newcastle upon Tyne To celebrate this step, two exhibitions are being held, at the Heaton Assembly Rooms, Heaton Road, Newcastle upon Tyne, during November 17–20, and at the Corporation Hotel, Corporation Road, Middlesbrough-on-Tees, during November 23–25 The exhibitions will show a representative range of equipment of the latest type for education, research and development and industry

Under the provisions of the Fulbright Programme, travel grants are available to citizens of the United Kingdom and dependent territories, to go to the United States for an academic or educational purpose, provided that they have adequate financial support in dollars for the visit, and have been accepted by an American institution of higher learning Grants cover the cost of direct travel between the candidate's home and the American university or institution They are available during June 1, 1960–August 15, 1960, for which applications must be submitted by March 14, 1960, and August 16, 1960–April 1, 1961, for which applications must be submitted by June 1, 1960 Application forms and further information can be obtained from the United States Educational Commission in the United Kingdom, 71 South Audley St, London, W 1

We regret that in the article entitled "Scientists in the Public Service in Britain" in *Nature* of September 19, p 858, the statement issued officially relating to Dr J W G Lund is incorrect Dr Lund is in charge of the algological research of the Freshwater Biological Association, of which Mr H C Gilson is director

BOOTS' NEW BIOLOGICAL RESEARCH LABORATORIES

By DR. G. I. HOBDAY
Director of Research

DURING a night-time air-raid on Nottingham in May 1941, nearly all the research facilities of Boots Pure Drug Co., Ltd., were destroyed. Blast and fire reduced virtually all the chemical and biological laboratories to heaps of charred rubble. The timing of this disaster could not have been more unfortunate. Under the stimulus of the national emergency we were expanding our research operations to enable the company to manufacture many vital drugs of European origin, supplies of which had been cut off by the War; penicillin, in the development of which we were to collaborate, was about to emerge. It was urgently necessary, therefore, to re-house our chemists and biologists as soon as possible. Because new construction was out of the question existing premises had to be converted. Choice of these was not easy since the Research Department was by no means the only one to suffer damage and every foot of space in the company's buildings in and around Nottingham was at a premium.

After due consideration, it was decided to re-house chemistry and biochemistry in a nearby building on the Island Street site and to evacuate the biological facilities, including bacteriology and pharmacology research and standardization, to a heterogeneous group of company buildings in West Bridgford, a Nottingham suburb. These latter, on which over the years a considerable amount of money has been expended, have served us well. Of course, it was evident from the beginning that they would answer our needs for only a limited period. But, as with many war-time expedients, building restrictions in the post-war years and the subsequent need to share out the capital cake among an increasing number of growing members of the company left us in occupation of them for longer than was originally intended. However, after about eighteen months of active planning we started construction of a new biological research building in September 1956, and occupation of it has just been completed.

The new building, which was designed by Boots' architectural staff, is sited in Nottingham a short distance away from the chemical manufacturing plant, but near enough so that services such as steam, electricity and water are drawn from the central works supply. It is near the present chemical and biochemical research laboratories and immediately adjacent to the site on which these facilities will be re-housed within the next few years. In plan, the building is in the form of an irregular H; one wing of four floors houses administration offices, Medical Department, library, canteen, conference room and a fully equipped lecture theatre seating 200; the linking block contains the main staircase and lifts together with lavatories and cloak-rooms; the other wing, longer than the first and on seven floors with a basement, is entirely laboratories. The total floor area is approximately 90,000 sq. ft. Externally, the building is of striking appearance; one wing is of brick and the other is faced with ceramic tiles in a checker-board pattern of grey and yellow. In internal design the administration wing and linking block are fairly conventional, but features of special interest include the pre-stressed concrete main staircase and the undulant ceiling in the canteen. The lecture theatre, which is acoustically designed, is fitted with stackable chairs which can be removed, entirely liberating the floor space for exhibitions, etc. Also to be noted is the pleasant medical and biological library housing 15,000 volumes, the stack room of which is fitted with mechanically operated stacking for economy of floor space. The décor throughout is modern, but not aggressively so, using mainly monochromatic treatments and avoiding disturbing colour contrasts. In the entrance lobby is a large colourful mural, abstract in design but intelligibly depicting the scientific disciplines provided for in the building.

The laboratory wing is functionally planned to accommodate the biological procedures employed, the common links throughout being laboratory animals and micro-organismal techniques. Required floor area and available site area comparison clearly pointed to a multi-storey building; this was quite acceptable, indeed in many respects desirable, since it permitted a plan of isolation of different functions on separate floors while reducing circulation distances

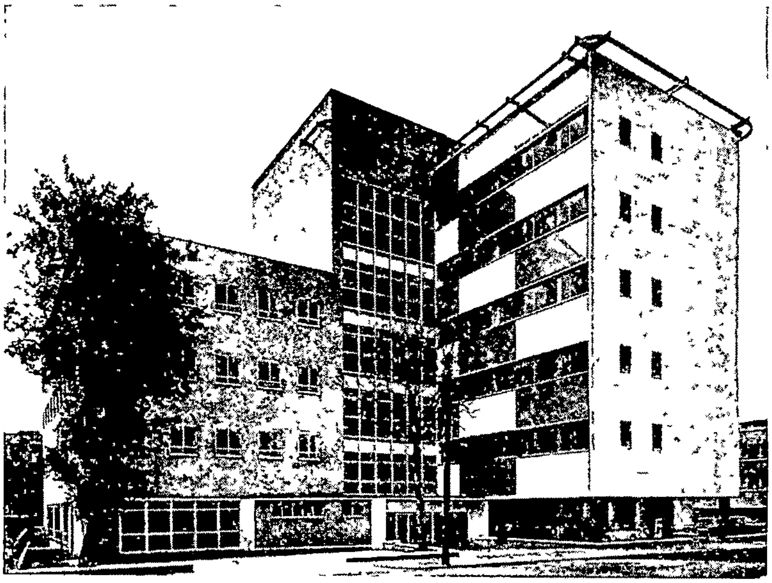

Fig. 1. Main entrance to Boots' Biological Research Laboratories. Administrative offices, library and lecture theatre are on the left; laboratories on the right

and simplifying centralized servicing The floors were planned on a 9-ft module in a block 200 ft long and 45 ft wide This plan gave a spinal corridor arrangement which again helped in the separation of functions, since it was easy to form the areas at both ends into isolation units A steel-framed building was chosen with space-frame girders 3 ft 6 in deep and 45 ft span By this arrangement none of the internal walls is part of the structure, permitting alteration of the working areas as the need arises ; it also provides a space between ceiling and floor above in which services are distributed Vertical distribution of services is through a duct, 10 ft by 17 ft , which goes right through the building from top floor to basement The whole of the laboratory wing is air-conditioned, inlet air being drawn in through an electrostatic precipitator and distributed through two separate systems, one serving the east side and the other the west side to give flexibility in taking care of solar gain through the large unopenable windows A plenum system is used with pressure differences carefully arranged especially in laboratories where micro-organisms are used All extracted air from areas of possible infection is filtered sterile before being vented to atmosphere Where necessary, 'hospital' finishes on walls and ceiling are employed to facilitate cleaning and sterilizing , floor coverings are sheet polyvinylchloride in laboratories and hard asphalt in animal rooms and wash-down areas Stainless steel benches and steel under-bench fittings are employed in all sterile areas and teak tops with wooden furniture elsewhere

Equipment cleaning and sterilizing are centralized in the basement, where all refuse is incinerated There are two systems of automatic hoists for handling separately dirty equipment to the basement and returning clean equipment to the requisite floors All equipment and material passing from the isolation areas are heat-sterilized before proceeding down the 'dirty' hoist Media-making is centralized and from a food store on the top floor animal diets are delivered to appropriate floors by chutes

Facilities for work with radioactive labelled substances are provided in a self-contained suite The main units of this are a synthetic chemical laboratory, a biological laboratory with separately vented cage cabinets and a radioactivity measurement laboratory The main radioactive store is in a shielded room in the basement

The work in the laboratories lies in the fields of pharmacology, toxicology, bacteriology, mycology, virology and parasitology Some routine testing and standardization work is done on chemical and pharmaceutical production material, such as sterility-testing of injections and bio-assay of insulin Otherwise the work is investigation, much of it comprising the biological component of research projects involving other research divisions For example, in the field of parasitology trypanosomiasis is a major project, and chemical substances synthesized in the nearby chemical research laboratories, or new antibiotics isolated in the antibiotic research unit, are screened in the new building by specialized laboratory tests Those of potential value will undergo more specific tests for activity and, in another unit in the building, for toxicity Any worthy of clinical or field trial will be passed over either to the Medical Department or to the veterinary research division at Thurgarton, about ten miles outside the city Work of this kind has produced 'Ethidium' and 'Prothidium' for treatment and prophylaxis of bovine trypanosomiasis In a similar way the parasitologists working on amœbiasis have contributed to the development of 'Entamide' for the treatment of amœbiasis Likewise the bacteriologists have collaborated with the chemists and pharmacists in developing a new antibacterial substance, 'Dybenal'

Team operations of this kind provide much of the impetus for progress in the search for new substances for the treatment of human, veterinary and plant diseases The new laboratories form a vital link in the chain of investigations between the first conception of a new drug and its final availability to the public They serve the future in providing the type of working accommodation which the young research scientists of to-day expect and need in order to make their most effective contributions in the fight against disease

THE BRITISH FOOD MANUFACTURING INDUSTRIES RESEARCH ASSOCIATION

THE British Food Manufacturing Industries Research Association Laboratories at Leatherhead were open to members on September 16 and to invited guests on the following day The wide range of the research programme of the Association was demonstrated, the exhibits covering work in progress for the eight main groups into which the membership is divided, that is to say, cocoa and chocolate, sugar confectionery, meat and fish products, jams and jellies, pickles and sauces, oils and fats (including margarine and compound cooking fats), bakers' prepared materials and miscellaneous products ranging from table jellies to salted nuts and potato crisps The work undertaken covers fundamental chemical, physical and bacteriological investigations alongside technological aspects of food manufacture

For the chocolate industry an item of major importance is the study of the rheology of molten chocolate An experimental viscometer was on show which had been designed and built to the requirements of the Association to give measurements of viscosity over a wide range of rates of shear A method of plotting the viscometric data has been developed which leads to the flow properties of chocolate being expressible in terms of two constants The glyceride composition of cocoa butter is being studied by chromatographic techniques Complete separation of the mono-unsaturated triglycerides has been achieved by reverse phase paper chromatography using a non-polar stationary phase and a suitably chosen mobile phase An investigation into the volatile constituents responsible for the flavour of cocoa and chocolate by gas chromatography is in its initial stage

The properties of high-boiled sweets, particularly their behaviour on exposure to the atmosphere, is being investigated by means of an apparatus which permits samples to be boiled under closely controlled conditions at low moisture content. The drying of certain types of confectionery deposited in starch moulds is being studied in two ways with the view of reducing the 'stoving time' necessary for their production. First, the effects of temperature and humidity on the rate of drying of gelatine and starch gums are being studied in a cabinet in which these factors can be closely controlled. Secondly, as corn-starch is used as a moulding medium, an investigation of its equilibrium relative humidity at elevated temperatures is of importance, and an apparatus for carrying this out has been devised and built by the staff of the Association. Other items of research connected with sugar confectionery manufacture are concerned with the properties of glucose used in confectionery (corn syrup), particularly the prevention of foaming on boiling and the tendency for the material to darken on storage.

The programme of research for the meat products group includes biochemical studies on residual tissue respiration and the measurement of oxidation-reduction potential. Colour changes and fading in cooked cured-meats are being studied with the aid of reflectance spectrophotometry. On the technological level, cooking properties of sausages and their colour stability during marketing are being investigated.

The Association's bacteriological laboratory is concerned on one hand with problems connected with bacterial spoilage of food, including the 'blowing' of canned goods, greening in cooked cured-meats and bacterial growth in vacuum-packaged bacon, and on the other hand, with bacterial aspects of the curing and processing of meat. Members are also advised on questions relating to general factory hygiene.

Problems connected with the canning of herrings are being studied by members of the Association's staff at the Torry Research Station, Aberdeen. The work involves chemical studies of herring flesh and the correlation of changes in the constituents of the flesh with flavour changes and with changes in texture which occur during the canning process.

The Association maintains close contact with horticultural stations concerned with the breeding and development of new varieties of soft fruits and helps the industry to assess their suitability for jam manufacture. The tendency for raspberry seeds to go 'blind', that is to say, become less visible, in jam is another problem which has engaged the close attention of the Association.

Much of the work in connexion with pickles and sauces is concerned with microbiological spoilage, and spoilage organisms from a large number of spoiled packs have been isolated and identified. Problems connected with the production of low-acid pickles involve studies of the pasteurization procedures necessary for a product which will combine adequate shelf-life with desirable appearance and eating properties.

In conjunction with the National Institute for Research in Dairying, an instrument for comparing the 'spreadability' of margarines has been developed. This instrument, the '*Fira/Nird*' extruder, has proved to have applications in connexion with other foods and, indeed, in other industries, where the rheological properties of semi-solid materials are important.

The Association maintains an extensive library of books and periodicals. Research reports and other publications are available only to members of the Association, who also receive monthly issues of abstracts from current scientific and technical literature. Some two thousand items are abstracted in a year.

B. R. Knapp

THE STRUCTURE AND CHEMISTRY OF PROTEINS

SYMPOSIUM ON PROTEINS AT PARKVILLE, AUSTRALIA

THE intensification in recent years of research relating to the utilization of the primary products of Australia, wool, meat, wheat and milk, and in medical research, resulted in the organization during September 10–11 of a symposium on "The Structure and Chemistry of Proteins", at the Division of Protein Chemistry of the Commonwealth Scientific and Industrial Research Organization Wool Research Laboratories, Parkville, Victoria.

The meeting was well attended, with eighty-five delegates participating. Several overseas visitors were present, including some who had attended a symposium on "Hæmatin Enzymes" in Canberra, immediately preceding the symposium on proteins.

The topics of the twenty-two papers presented ranged over many of the fields currently being investigated in other parts of the world, a notable exception, however, being studies of amino-acid sequences. This reflects the pre-occupation of Australian workers with the isolation and characterization of protein components from natural products as a necessary first step to a more comprehensive understanding of their structure. Although the complex protein mixtures of these products are the focal point of much of the Australian research, studies involving purified soluble proteins, such as insulin and lysozyme, plasma albumin and other proteins as well as synthetic peptides are, however, also in progress. The rapid advances which are being made in our knowledge of the amino-acid sequence, structure and behaviour of these classical proteins assist in the understanding and interpretation of the chemistry of the more complex biological systems.

The contributions that X-ray, infra-red and electron-microscope investigations have made in the study of the structural organization of keratin were illustrated by the work of R. D. B. Fraser, T. P. MacRae and G. E. Rogers. The application of X-ray crystallography to the study of the three-dimensional structure of a simpler compound, toluene-*p*-sulphonyl-L-prolyl-L-hydroxyproline monohydrate, was described by J. Fridrichsons and A. McL. Mathieson, and this contribution emphasized the stereo-chemical problem encountered with prolyl residues in a polypeptide chain. The properties of protein complexes of the insect cuticle were described by R. H. Hackman and interest was aroused in the nature of their strong bonding to chitin and quinones. The isolation of nucleoproteins and labile plant viruses from leaves and their susceptibility to degradation by salt were discussed by J W Lyttleton

The chemistry of thiols and disulphides is a prominent feature of protein chemistry and was exhaustively discussed S J Leach and J M Swan described the important analytical advances made in this field with the aid of the polarograph and the preparative applications of sulphite in the presence of an oxidizing agent, such as cupric ions The various methods of splitting disulphide bonds and their application in the extraction of soluble proteins from wool were discussed by J M Gillespie, I J O'Donnell and E O P Thompson, and H Lindley reported on the varying reactivity of the disulphide bonds of insulin J M Creeth and D J Winzor were concerned with the specificity of the reaction of iodine with the sulphydryl groups of ovalbumin, while the important role of thiols in disulphide interchange reactions was clearly apparent in the experiments of F J R Hird, R Frater and J R Yates on the nature of cohesive forces in dough Disulphide interchange was also responsible for the inhibition of several —SH enzymes by 'sulphanilamide disulphides' in an investigation reported by E Boeri and L Brighenti

The physico-chemical characterization of proteins isolated from naturally occurring mixtures was covered in a further series of papers The aggregation and disaggregation of soluble proteins and the changes induced during denaturation figured prominently in the discussions of papers presented by J M Creeth and L W Nicol on urease, by B S Harrap, I J O'Donnell and E F Woods on soluble wool proteins and by H A McKenzie on various enzymes and globular proteins The various techniques used to follow conformation changes were critically examined and it became clear that the behaviour of a particular protein in any given system was not necessarily indicative of the behaviour of other proteins in the same system The surface denaturation of proteins was discussed by F MacRitchie and the application of the spread monolayer techniques to a comparison of the surface chemical properties of various cereal proteins was described by N W Tschoegl The preparative applications of electrophoresis were illustrated by the work of J F O'Dea on the isolation of components of serum while P R Carnegie and R L M Synge described the electrophoretic behaviour of cupric complexes of oligopeptides and a possible method for selectively isolating dipeptides from mixtures of peptides

Chromatography as an aid in the purification of proteins was introduced by A G M Marr, who described the fractionation of serum proteins on 'DEAE-cellulose' D H Simmonds has applied this technique very successfully to the water-soluble flour proteins and he also reported amino-acid analyses of the various fractions using ion-exchange chromatography with an automatic recording apparatus capable of handling eight ion-exchange columns eluted simultaneously. The continued interest of chemists in the quantitative analysis of protein constituents was evident in this paper and that of J H Bradbury on an alternative method requiring paper chromatography of dinitrophenyl amino-acids This method was particularly applicable to the estimation of amide groups

G Coleman and W H Elliot described their work on the synthesis of α-amylase by *Bacillus subtilis* and C J Shepherd discussed the effect of inhibitors of protein synthesis in *Aspergillus nidulans*

A feature of the symposium was a lecture by Dr R L M Synge on 'Naturally Occurring Peptides and Their Biological Significance" Although the search for naturally occurring peptides has not been intensive it was apparent from the stimulating survey by Dr Synge that many unusual types of small peptide are already known He went on to stress the necessity for quantitative data in the study of protein synthesis and expressed concern at the lack of experimental documentation for many of the generalizations by biochemists regarding the synthesis of proteins A spirited discussion ensued and was continued in a subsequent session on protein synthesis

Participants in the symposium were fortunate in having a range of papers presented covering most of the rapidly growing areas of investigation in the protein field and it may be hoped that similar conferences will be held in the future

E O P THOMPSON

ELECTRONICS EXHIBITION

THE fourteenth Exhibition of Electronic Devices, organized by the Northern Division of the Institution of Electronics, was held at the Manchester College of Science and Technology during July 9–15 This annual exhibition is now well established and it provides an opportunity for new electronic apparatus to be demonstrated in rather less crowded conditions than obtain at the Physical Society Exhibition held in London during January

A lecture programme was associated with the exhibition and, as is to be expected, a substantial part of this programme was devoted to transistor techniques However, topics of general scientific interest were by no means excluded, and lectures on the argon chromatograph, on photographic densitometry and on the use of X-rays for micro-analysis were well attended

The exhibition was divided into a manufacturers' section and a research section, the research exhibits forming much the smaller part of the whole A relatively small number of research exhibits, especially from universities, has also been evident at the Physical Society Exhibition Although research exhibits are of considerable general interest, and of special interest to those working in related fields, it is probable that for scientific workers as a whole the more important function of an exhibition of this type is to show instruments that are currently available In the manufacturers' section this year's exhibition was notable for the extent of the exhibits of the various electronic agencies These agencies handle the products of a number of manufacturers and they hold stocks of instruments and components In the case of one agency the display occupied a whole room and included examples of the products of some sixty manufacturers

Included in the new equipment on show were examples of 'second generation' oscilloscopes Until very recently, British manufacturers have been unable to offer high-performance oscilloscopes having trace brightness and amplifier band-width suitable for the display of single-pulses having fractional microsecond duration This has meant that workers in such fields as nuclear physics and high-speed computing have either obtained equipment from North America or have constructed their own display systems New types of oscilloscopes are now available from Messrs Cossors, EMI, Marconi Instruments and Solartron The cathode-ray tubes are mostly of the post-deflexion acceleration type and run at voltages of 6–10 kV., amplifier band-widths are 10–20 Mc /s , and the deflexion sensitivity at full gain is about 100 mV per cm This specification is adequate for all but the fastest applications, and for these, two manufacturers are offering oscilloscopes with distributed amplifiers having a band-width from d c to 40 Mc /s Messrs Cossor and Heathkit showed kits of parts that can be assembled to make items of test gear such as valve-voltmeters and simple oscilloscopes The kits normally employ printed circuits, which simplify the wiring, and can be assembled with semi-skilled labour A wide variety of silicon devices are now available, and Messrs Ferranti showed a range of silicon photo-voltaic cells , these have a response time in the microsecond region and have applications in equipments using modulated light The new cells have a high conversion efficiency and in the larger sizes can be used as solar cells to provide electrical energy from sunlight

This annual exhibition continues to be well attended and it provides an opportunity for scientific workers in the north-west of Britain to keep abreast of current electronic equipment and components

V H Attree

UNITED KINGDOM CIVIL SERVICE COMMISSION

THE ninety-third annual report of the Civil Service Commissioners, covering the year April 1, 1958–March 31, 1959, records an increase in the number of candidates successful in open competition from 13,057 to 14,616, but for the administrative class the number of successful candidates decreased from 39 to 37, though well above the 1956–57 figures, and some departments were short of recruits, although the number of unfilled vacancies is not large (Report of Her Majesty's Civil Service Commissioners for the period 1st April, 1958 to 31st March, 1959 Pp 36 (London H M Stationery Office, 1959) 2*s* 6*d* net)

The Commissioners are continuing their efforts to attract a larger number of good candidates from the universities Candidates in the limited competition for the administrative class further decreased in number Recruitment to the senior branch of the foreign service was also disappointing, and the shortage of candidates for the statistician class persists Less than 50 per cent of the declared vacancies as patent examiner have been filled and there was again a shortage of good candidates for scientific officer, engineering and draughtsmen posts, and many vacancies remain unfilled, particularly through a dearth of physicists Grave shortages remain in the telecommunications and other electronic fields , however, there was a small increase in the number of candidates in the senior scientific officer competition and most of the vacancies which had been notified were filled.

Applications in the assistant experimental officer/experimental officer competition remained remarkably steady and generally sufficient candidates were successful to meet departmental needs The supply of biologists again exceeded the limited demand The research fellowship competition continued to attract interest from workers in all fields of research, and thirteen candidates were offered the award There is some evidence that it is becoming harder to attract good applicants for junior fellowships

Results of interviews in Ottawa and Washington in April 1958 to select applications for research fellowships and scientific officer posts were less satisfactory than originally appeared likely, and in the event only one candidate joined the Service as Research Fellow and one as a senior scientific officer, although some well-qualified men appear to have been stimulated to return to Great Britain in the universities or in industry

EUROPEAN NUCLEAR ENERGY RESEARCH

THE seventh annual report of the Netherlands'–Norwegian Joint Establishment for Nuclear Energy Research*, describing the work of the Establishment during the period July 1, 1957–June 30, 1958, mentions that the research reactor, *Jeep*, was in almost continuous operation at 450 kW during the year, with a total release of heat of 105 6 MW days, but that the corrosive effects of the heavy water have grown worse and a minor leakage of heavy water occurred during April The completion of the Halden boiling water reactor, which is an Institutt for Atomenergi project and which is situated inside a rock excavation near the paper pulp factory, Saugbrugsforeningen, will be delayed by about a year because of construction and design problems The reactor tank was completed during the spring of 1958 The necessary amount of heavy water which was purchased from the United States of America is now stored at Halden, and part of the uranium ordered from Great Britain has been delivered An agreement between Norway, Denmark, Sweden, Austria, Great Britain, Switzerland and Euratom, on the joint operation of the reactor, was signed by representatives on June 11, 1958

Because of the higher demand for radioisotopes, and technical improvements in the production system, the number of isotope deliveries from Kjeller to customers outside the Establishment increased by 33 per cent over the previous year The deliveries were mainly to the Scandinavian countries. Detailed information about the type of isotopes produced and their distribution is given in the report. Separate sections deal with the activities of the Chemistry, Metallurgy, Reactor Engineering, Physics and Health Physics Divisions. The chemical analysis of uranium and D_2O is now carried out on a routine basis and the spectrographical methods used for impurity control of medical isotope products and the determination of plutonium have been improved. The main task of the metallurgical group has been the production of UO_2 pellets, and in addition to considerable computational work and experimental tests connected with the Halden boiling water reactor project, the Physics Division has obtained new neutron diffraction data on U_3O_8 and U_4O_9. The Health Physics Division is responsible *inter alia* for the daily radiation monitoring in the laboratories; the radiochemical analysis of biological specimens; and the general medical check-up of personnel. Of the 191 persons controlled by the Division during the year, only one received a radiation dose exceeding 5 rems.

---

* Seventh Annual Report, July 1957–June 1958, of the Netherlands'-Norwegian Joint Establishment for Nuclear Energy Research Pp 32 (Kjeller near Lillestrøm Netherlands'-Norwegian Joint Establishment for Nuclear Energy Research, 1959)

The Netherlands–Norwegian Reactor School was officially opened on April 12, and the first nine weeks standard course commenced on April 14 with twenty-eight students: fifteen from Holland, eleven from Norway and two from Switzerland. The construction of the new isotope building was started in January, and of an office building to house the ship propulsion group and the Engineering Division in April. As in former years, the Establishment benefited from the exchange of scientists with similar institutions in other countries. Seven guest scientists worked at the Joint Establishment for Nuclear Energy Research for the whole or part of the period under review. The two sponsoring organizations of the Establishment, the Reactor Centrum Nederland and the Institutt for Atomenergi, took part in international co-operation in the field of atomic energy, in particular, in the European Atomic Energy Society, the Organization for European Economic Co-operation, and the International Atomic Energy Agency. Summaries of the main activities of the two organizations are given in the appendixes to the annual report.

THE FRANKLIN INSTITUTE

THE Board of Managers of the Franklin Institute in presenting their annual report for 1958 (*Journal of the Franklin Institute*, 267, 317; April 1959) express their gratification at the progress during the year in all the Institute's programmes of service to science, but point out that without increased funds the Institute cannot expand and may not be able to maintain its present activities. In addition to the Franklin Institute Laboratories and the Computing Center, both located in Philadelphia, the Institute owns and operates the Bartol Research Foundation in Swathmore, Pennsylvania, and is trustee for the Biochemical Research Foundation in Newark, Delaware. The Institute conducts basic and applied research on a contract basis for government, industry and private concerns, and the Computing Center co-operates with the Laboratories which carry out projects under contract in the fields of engineering and the physical sciences. The Bartol Foundation is concerned with the study of fundamentals in physics, low-energy exploration and cosmic phenomena, and the Biochemical Foundation with cancer research.

It was to be expected that public interest in the activities of the International Geophysical Year, and in rockets, satellites and space travel, would largely colour the work of the Education and other divisions of the Institute during 1958. Of the twenty-one lectures presented at the Institute meetings during the year, eight were on subjects related to the space age; the exhibit, "Progress of Time", contributed to the Institute's Science Museum by the Hamilton Watch Co., included the Mars Space Clock, and other loan exhibits showed the successful launching of the *Explorer* rocket, the *Vanguard* satellite, and the *Pioneer* lunar probe; new presentations in the Planetarium were "The American Satellite" and "Astronomy in History", and the staff of the Planetarium were responsible for the operation of the Institute's Moonwatch Station; and the series of ten semi-technical lectures on astronautics sponsored by the Astronomy Department were published in December as Monograph No. 6 entitled "Ten Steps into Space".

The Library of the Institute, which began as a small collection in 1824, now comprises 162,054 volumes, of which 3,054 were acquired during 1958—986 by purchase, 544 by gift and 1,524 by binding. New accessions included eighteen Russian periodicals, four in translated English editions, and a remarkable set of the owners' file copies of records and correspondence of the Penang Sugar Estates Co. (British Malaya), comprising twenty-three handwritten volumes of the work of the Company during 1876–97. A symposium on "Thermoelectric Effects" was held on September 8, primarily for research workers in this specialized field, and an all-day symposium on "Odour" on October 21 during the "Cleaner Air Week" in Philadelphia. Three new titles were added to the series of monographs published under the auspices of the *Journal*: "Particulate Emission", "The Airways Modernization Board—Its Mission and Methods" and "Ten Steps into Space" mentioned above.

Details are given in the illustrated report of the long-range research programmes and new developments of the separate research organizations. These include air-pollution research; thermoelectricity and semiconductors; electron microscope studies of dislocations in metals and zone refining of reactive metals; the physics of polymers; and flow loops in nuclear engineering. A novel etching technique has been developed for studying dislocation loops generated in metals under stress and their motion and growth in zinc have been filmed (*Journal of the Franklin Institute*, 267, 335; 1959). A simple sonic-vibration method for the early detection of glaucoma has been demonstrated and an all-transistorized sensitive cane for use by the blind has been successfully tested. The report concludes with brief details of the finances of the Institute, the membership and staff.

ECONOMIC DEVELOPMENTS IN THE MIDDLE EAST

IN a report dealing with developments for the year 1957–58, published by the United Nations as a supplement to the world economic survey of 1958, there is included a useful survey of agricultural production and development, industry, petroleum production, and foreign trade in the several main countries included in this politically highly sensitive world region (Iran, Iraq, Israel, Jordan, Lebanon, Saudi Arabia, Sudan and Turkey) About one half of the text deals with factual summaries, and about one half gives statistical tables (Economic Developments in the Middle East, 1957–1958 (Supplement to World Economic Survey, 1958) Pp viii+104 (New York United Nations , London H M Stationery Office, 1959) 1 25 dollars , 9*s* , 5 Swiss francs)

The information given regarding the key product, oil, has special interest The rapid recovery and expansion of this industry during 1957 (after the decline in production as a result of the Suez crisis) is remarkable In 1957 there was an increase over 1956 of only 3 7 per cent, but this advanced by a further increase of 20 7 per cent in 1958 The total production of the Middle East as a share in world production rose to 23 6 per cent in 1958 as compared with 20 per cent in 1957 The main contributors to the large rise in oil production were Iran and Kuwait, but though producing relatively small quantities, other countries have been expanding their output at a high rate, and a new entrant was Syria where, in the north-east of the country, a field was discovered in 1958 estimated to have an output capacity of about 2 million tons Agricultural production in the same year shows continued expansion at the rate of about 3 per cent per annum, both in food production and in the output of industrial cash crops on which the several countries depend as a major source of foreign exchange It is significant that the rate of growth in both exceeded the growth of population A continued shift in the pattern of production towards industrial cash crops and greater use of fertilizers and agricultural machinery helped to maintain the rate of agricultural output, but the uncertainty of climatic conditions caused wide fluctuations

Apart from the physical difficulties affecting production within the region, two comprehensive programmes of agrarian reform were started in the Syrian region and in Iraq late in 1958, and the social change and redistribution of income that these are likely to produce will very probably have a strong impact on the shape of future economic development From these economic changes within, there emerges a picture of foreign trade and payments showing much variation, and with interesting evidence of change in operation leading to shifts in the geographical direction of trade, particularly of the cotton exporting countries , thus the United Arab Republic and Sudan moved away from Western Europe and the United States toward the U S S R , Eastern Europe and the Far East Iran, Jordan, Turkey and Israel, on the other hand, maintained their high share of trade with the United States and Western Europe, although an increasing proportion of the exports of Israel and Turkey went to eastern European countries in 1957 and 1958 Oil exports show a significant increase in their share to Asia and the Far East, though the dominant traditional markets in Western Europe are maintained ALICE GARNETT

THE NATURE OF POLISHED METAL SURFACES

HOOKE, Newton and Herschel all held that the asperities in a roughly ground surface are cut away during polishing, leaving a series of fine grooves , the finer the polish the finer these grooves or 'scratches'. Rayleigh agreed that the asperities are worn down but thought that the material is removed in an almost molecular fashion In 1921 Beilby advanced the radical view that, instead of the asperities being worn away, the depressions in the surface are filled in by material which is smeared across the surface, covering it with a layer which he thought was glass-like or amorphous in character This has come to be known as the 'Beilby layer' The idea of the layer being truly amorphous has been modified slightly in more recent times, but the basic concept of a layer which is physically distinct from the substrate and which has lost its obvious crystalline properties is still retained

Beilby did not propose any specific smearing mechanism, although he inferred that surface tension forces were responsible A most plausible mechanism was afterwards advanced by Bowden and Hughes which was based on observations that very high local temperatures can be attained when two solids rub past one another They suggested that asperities in the surface are melted when abrasive particles rub across them, the liquid so formed depositing in and filling adjoining depressions It was further proposed that, due to very rapid chilling, this molten material solidifies in an amorphous-like condition

A paper by L E Samuels reviews work carried out at the New South Wales Branch of Defence Standards Laboratories which strongly supports the earlier view that polishing is essentially a fine cutting process, and is believed to establish with reasonable certainty that the Beilby layer does not exist

The new theory is that metallographic polishing occurs primarily by cutting, the individual abrasive particles acting in a similar manner to a planing tool Material is removed and scratches are produced , the better the polish the finer the scratches The surface is crystalline but deformed, the magnitude of the deformation decreasing with increasing fineness of polish to a surprisingly low level in the case of the finest polishes Moreover, the deformation decreases rapidly with depth so that comparatively perfect material is exposed by a very light etch (*Austral J Sci* , 21, 6 , 1959)

EEL MIGRATION

It seems probable that many of the difficulties that have undermined Dr Tucker's belief[1] in the ability of European eels to return to the Sargasso Sea would have disappeared if he had compared the European eel with the Atlantic salmon, the return of which to spawn after a migration of comparable difficulty is more readily demonstrable

Salmon, both Atlantic and Pacific, migrate to feed in the sea · here they may stay for one and a half to four or more years This active feeding period is followed by a spawning migration during most of which the animal does not feed Fasting begins as the salmon nears fresh-water, the subsequent migrations upstream, often carried out under difficult physical conditions, are very fatiguing and call for a considerable expenditure of energy Yet, after a migratory fast lasting up to a year, millions of salmon survive to partake in most energetic spawning activities In fact, about 5 per cent return to spawn again, and a small proportion may spawn three times

Eels spend most of their lives feeding in fresh-water This feeding period of from six to twenty-five years duration is as clearly preliminary to spawning migration as are the years spent by the salmon in the sea I do not agree with Dr Tucker that European silver eels are starving and debilitated the many thousands that I have handled have been vigorous, extremely energetic and in good condition It is of interest that eel-dealers store living eels for long periods, yet these eels are in the end still fat enough to be sold as highly nutritious food

On their 3,500-mile spawning journey, eels have to contend only with slow-moving ocean currents, not to be compared with the fast-flowing streams encountered by salmon If eels travel at a modest 40 miles a day, the journey need take only thirteen weeks—not a long fast compared with that of many salmon

Dr Tucker claims that American eels, because of their larger size and apparently juvenile sex condition, are better suited than European eels for their spawning migration But size is not a criterion of condition, salmon, ranging from 3½ lb to more than 60 lb, complete their spawning migration successfully; many reach the rivers of Britain in an advanced stage of sexual maturity, fast, and survive to spawn Recent examinations of the state of the gonads in large samples of eels have convinced me that the European silver eel is not "already well advanced towards being a reproductive oceanic fish" The gonads of silver eels are not in an advanced stage of development Many silver eels migrate when their gonads are scarcely more advanced than those of yellow eels In fact, the gonads of the silver eels are in about the same developmental stage as those of female salmon smolts and unspawned male smolts

One of the most strongly emphasized points in Dr Tucker's argument is that European silver eels are rarely caught at sea But neither apparently are American eels Nor is it surprising that eels at sea are elusive They do not feed and so cannot be caught on long-lines, nor are they likely to stay captive in any normal deep-sea trawl It is no cause for astonishment that eels are not caught in the Straits of Gibraltar, for no commercial fishing gear in use there can be expected to catch eels Salmon are rarely caught off shore, and salmon should be much more catchable, for they feed in the sea, they stay there much longer and they are not so shaped as to make escape from nets easy Yet countless millions reach their spawning grounds yearly, though the number caught in the open sea is very small

Finally, Dr Tucker's hypothesis requires that a large proportion of the American eel population is 'lost' yearly as a reproductive potential, since American eels which spawn in the wrong place produce progeny which become European eels and never succeed in spawning If this were a true account, there would be intense selection in favour of eels which found the 'right' spawning ground It would be very surprising if natural selection on this large scale had failed to eliminate the European eel in a few generations

J W Jones

Zoology Department,
University, Liverpool

---

[1] Tucker, D W, *Nature*, 183, 495 (1959)

I must emphasize at the outset that Dr Jones's communication, even if it were acceptable in its entirety, contains nothing relevant to the fundamental problem of eel navigation and nothing which has any bearing upon my hypothesis that the two Atlantic *Anguilla* phenotypes may be environmentally differentiated and distributed without genetic intervention For the rest, the difficulties which led to a heavily documented paper[1] are not likely to be dispelled by criticism which ignores not only literature already cited, some of it on two occasions[1,2], but also that relevant to its own substantiation Moreover, a recent independent review[3] has made such a comparison as Dr Jones demands, and without detriment to the new theory of eel migration

Both the salmon and the eel undergo migrations which raise problems of navigation, physical effort, condition and osmo-regulation Thereafter the comparison breaks down to such an extent that knowledge of one casts little light on the ways of the other The eel is catadromous; the salmon anadromous The first migration of the eel is as a larva passively transported in the surface layers; its second as a starving adult travelling in the deeper layers and probably by a different return route Both of the migrations of the salmon are accomplished as an adult fish, travelling in substantially the same water-masses along the same routes and actively feeding until the final return to fresh-water Eels are in peak condition shortly before the commencement of their final journey; salmon shortly before the end of it

The European eel is, in Dr Jones's view, an ocean traveller, accomplishing a long journey of at least 3,500 miles for the south-west European stocks and at most 5,000–6,000 miles for the White and Black Sea stocks The longest recorded journey for an Atlantic salmon is 1,730 miles in 328 days[4], characteristically, its migrations are much shorter—a few hundred miles along the coast or to and from feeding-grounds off the shelf—and fairly easily explained by internal changes in the osmo-regulatory mechanism which prompt it to seek salt or fresh water and by a proved propensity to wander along the coast until it smells the outfall of its native stream. However arduous the last stage of the journey of the salmon up-river, it can and does alternate activity and rest and make use of slack water and pools for the latter purpose; for the eel in an opposing ocean current no such respite is possible without losing ground.

Segregation of breeding stocks of salmon provides excellent opportunities for adaptive variation and variation of inherited behaviour-patterns through genetic isolation; in the eel nothing of the kind is possible.

Given this summary of the habits of the two fishes, which further have very different patterns of locomotion and are widely unrelated, I see very little ground for generalization from one to the other; the analogy is rejected with good reason, but Dr. Jones should not assume that it was ignored.

Salmon survival for subsequent spawnings is due in part to the fact that degenerative changes in the gut are confined to the mucosa, which is renewed in kelts that recover[5]; in the eel the changes are profound and lead ultimately to complete destruction of the gut[2,6]. The personal findings of Dr. Jones, like those of Prof. D'Ancona previously dealt with[2], do not affect the evidence that the gut of the European eel is self-destroyed before the fish is more than a few hundred miles offshore.

Here a new point may be introduced. Experimental work on the eel has shown that in the sea it contrives to maintain effectively the internal environment of the freshwater fish. It does this by swallowing sea water, absorbing water and salts through the intestine, excreting an isotonic urine and discharging surplus chlorides through the secretory cells on the gills[7]. In European eels, once degeneration of the gut has proceeded merely far enough to impair the absorptive function, this mechanism can no longer operate; osmo-regulation must then depend wholly upon the relative impermeability of the body mucus and upon compensating liberation of water through breakdown of stored lipo-proteins. Failure of the whole apparatus would lead to rapid exsiccation and death. Experimentally induced failure, by preventing eels from swallowing sea water, does in fact produce an 11–14 per cent loss in weight and death within 3–4 days[7]. This situation, even more than the likely inadequacy of the food reserves to provide for locomotion, physiological work (for example, in chloride secretion) and gonad maturation, could account for the failure even of Mediterranean eels to reach apparently suitable breeding-grounds in that sea (*post*).

I am not subdued by Dr. Jones's experience with thousands of eels. The great curse of the voluminous work upon eels, upon the Salmonidae and upon sundry other animals, has been that too much of it has been mechanical and repetitive, replete with experiments unintelligently planned and mountains of data inadequately pondered, parochial alike in the range of its geographical experience and in its isolation from relevant literature from alien countries and related disciplines.

The physiology of the eel is not "clearly preliminary to spawning migration"; it could be, and I think is, atavistic and doomed to fruitless failure. We have no right to assume climax as normality in any incomplete behaviour-pattern or physiological process when climax has never been observed and no unequivocal circumstantial evidence of climax is available.

I agree that a 'stored' silver eel may well retain its condition like any other relatively quiescent animal; migrating eels, however, lose up to 20 per cent of their weight before they leave the Baltic[8] (reserve fat amounts to about 25 per cent) and this over periods greatly in excess of that shown to be necessary for the initial osmotic adjustment[7]. Either the food reserves are being rapidly used up, or there is a loss of water showing that the osmo-regulatory mechanism is already breaking down under the quite low salinities of the Baltic.

Dr. Jones suggests a hypothetical "modest 40 miles a day" over thirteen weeks for the eel migration. Norwegian work[9] summarized by Menzies[10] has shown that, of 598 long-distance journeys by marked and recovered salmon, 569 were accomplished at 5–25 miles a day and only twenty-nine at higher speeds up to 62 miles a day. Speeds for Baltic eels marked on a comparable scale[8] (the work was cited previously[1]) are in general between 5 and 10 miles a day; the record is 32.5 miles a day sustained over a mere two days.

Comparative data for condition of American and European eels are hard to come by. Vladykov[11] gives 411 gm. for the mean weight of Quebec bronze eels of 61 cm., compared with Frost's 425 and 414 gm. for 61 cm.[12] Windermere yellow and silver eels, respectively. The superficial agreement does not allow for the fact that the American eels cited are at an earlier and probably much younger stage, nor deny that the average weight of migrating American females is four times greater than that of the European, that their maximum sizes and weights are greater and their potential journey much shorter. I do not think we can avoid the conclusion that the American eels are better prepared. Dr. Jones's citation of the range of weights of salmon grilse is meaningless without an indication of the success-rates at different sizes and of the conditions overcome. Such data as are available for the migration speeds of the outward-bound salmon smolt[13] show that these are much slower than those of the larger returning grilse. Further, maximum velocity in fishes is a function of length and frequency of tail-beat; though the latter does fall with increasing size, larger individuals are faster swimmers[14].

My paper[1] mentioned merely "perceptible enlargement of the gonads", a statement in agreement with Dr. Jones's findings. It then proceeded clearly to specify those characters of migration livery and bathypelagic adaptation in which, by comparison with the American eel, the European may be regarded as advanced.

A surprising variety of fishes, including other Apodes, have been taken in deep-sea trawls by scientific expeditions; I have before me 29 *Synaphobranchus* from a single haul of an Agassiz trawl at 1,300 metres. There are at least 108 cases of records, with Scottish interest alone, of salmon taken at sea, 82 by trawls and various nets[15]. Salmon are surely less numerous than eels; being capable of a maximum velocity of 10 m.p.h. for short periods[16], compared with the eel's peak 2.6 m.p.h.[17], they should have greater chances of avoiding nets and not less. The infrequency of capture of eels in European seas remains significant. Non-capture of American eels is agreed; there is, however, no convergence of essential migration routes and intensive trawling comparable to that of north-west Europe. I did not write of "commercial fishing gear" in the Strait of Gibraltar but of an "intensive study"; still more explicitly, scientific investigations by Danish, French and Monagasque expeditions

Evolution by natural selection of a population which chose the 'right' spawning-ground would be conceivable enough in the case of, say, salmon in polluted and unpolluted tributaries of the Welsh Dee The case of the eel is not so simple The Atlantic *Anguilla* forms are believed to be environmentally differentiated by differences in the temperature stratification[1] and are certainly differently distributed by the various movements of the surface layers of the Sargasso between lat 20° and 30° N In the underlying deep waters in which the eels breed, the temperature and salinity conditions at a given depth are relatively uniform over a wide area , it is therefore unlikely that any sensory discrimination could pick a 'right' spawning-ground directly related to a 'right' surfacing-area Selection in relation to travelling and ripening times could not have any genetic effect owing to the failure of the current-system to return the larvæ precisely to the parental starting points along the American coast While the new hypothesis may seem more spectacular, it is statistically no more remarkable than the normally high infantile mortality-rate accepted in marine animals , the survival-rate is still sufficient to maintain the population Parallel cases of expatriated populations failing to breed are the British *Octopus vulgaris*[18], the Norwegian *Palinurus elephas*[19] and the Lagos *Branchiostoma nigeriense*[20], all of which are maintained by immigrations of larvæ bred elsewhere and so represent similar cases of wasted reproductive potential

There is likewise no ground for belief in selection producing genetic restriction of the eco-phenotypic variability potential of the Atlantic *Anguilla*, that is, eliminating the phenotypes with 110–119 vertebræ as such, as opposed merely to those going to Europe

Some further evidence in favour of the new hypothesis is now briefly noted

Possible parallel cases Bruun[21] has commented on the hitherto unexplained coincidence that, of four pairs of Atlantic apodal 'species', having distributions roughly similar to those of the two types of *Anguilla* larvæ and, moreover, larvæ which can be taken "at the same place and same depth within a certain area of the Sargasso Sea", the American 'species' of each pair has the lower number of vertebræ (Table 1) This situation may well be due to a common eco-phenotypy rather than to coincident genetic effects

Table 1 NUMBERS OF VERTEBRÆ OR MYOMERES IN SOME NORTH ATLANTIC EELS, MAINLY AFTER BRUUN (REF 21)

	East Atlantic	West Atlantic
Anguilla anguilla	110–119	—
Anguilla rostrata	—	103–111
Conger conger	154–163	—
Conger oceanicus	—	140–149
Synaphobranchus kaupi	143–154	—
Synaphobranchus infernalis	—	131–140
Leptocephalus euryurus	111–119	—
Leptocephalus similis	—	104–113

Likewise, Tambs-Lyche[22], supporting the new hypothesis, has suggested that there is a similar pseudo-speciation in the Atlantic Paralepid fishes (order Iniomi)

Extended pelagic phases 'European' eel larvæ grow to a greater length and unmetamorphosed age than the 'American' and are, on the new hypothesis, regarded as an extended pelagic phase of one species Parallel cases of facultative prolongation of larval or juvenile life in marine animals under conditions unfavourable to metamorphosis occur in the surgeon-fish *Acanthurus hepatus*[23], the frogfishes *Antennarius* spp [24], the *Macrotritopus* larvæ of the benthic octopus *Scaeurgus unicirrhus*[25], and in numerous Decapod Crustacea[26]

Selection of breeding-grounds by Anguilla *and* Conger On the old hypothesis, *Anguilla anguilla* and *A rostrata* were separate species with distinct breeding-grounds in the Sargasso Sea The American *A rostrata* and *Conger oceanicus* shared a common breeding-ground The European *C conger* shared the only breeding-ground of *A anguilla*, but also used other breeding-grounds between Gibraltar and the Azores and inside the Mediterranean[27]

I have already noted the fact that *A anguilla* does not breed in apparently suitable areas much nearer Europe than the Sargasso[1] The paradox raised on hydrological considerations is now reinforced by *Conger conger* acting as a biological indicator We may conclude that the 'European' eel is not breeding in the Sargasso, any more than it is in the Mediterranean or Eastern Atlantic

Location of the Anguilla rostrata *breeding-ground* I previously suggested that the *A rostrata* breeding-ground had been placed too far west[1] In support of this contention, be it noted that, until 1920, catches of *A rostrata* larvæ from all sources totalled only 34 specimens[28] In 1920 the *Dana* took a further 1,000 specimens ; because, however, her track out of Porto Rico towards New York[29] followed the north-east boundary of the 15 mm *A rostrata* contour, it follows that data for and within that contour remain thoroughly inadequate The probable breeding-ground between *c* lat 20–22° N, long 50–60° W has not been investigated at the proper season Material of the other American Apodes cited above is likewise scanty by comparison with the European[21,27]

MECHANISM OF ANIMAL JOINTS

Sponge-hydrostatic and Weeping Bearings

ANIMAL joints are very efficient pivots Charnley[1] gives 0 01–0 02 as the friction coefficient of a human ankle joint and shows that this low friction does not result from hydrodynamic lubrication He points out that ordinary boundary (thin-film) lubrication would produce five or ten times the observed friction and suggests that Nature may have discovered, in its combination of cartilage and synovial fluid, a system which is very slippery even under conditions of boundary lubrication The purpose of this communication is to propose an alternative system, which is, in fact, an example of a new and interesting class of bearings The principle is illustrated by the experiments to be described

A piece of closed-cell sponge rubber (cell size 0 7 mm and less) had one of its impervious cover sheets cut off to expose the cells This surface, lubricated with soapy water, was placed against a glass plate with a loading of about 40 lb /in ^{2} The friction coefficient was then measured as a function of the time for which the load had been applied (Fig 1, curve *a*). The friction coefficient is extremely low, but rises in the course of an hour or so If the sponge is separated from the glass for a few moments and then replaced, the friction falls to its initial low value This is consistent with the idea that most of the load is supported in a frictionless manner by the little volumes of liquid trapped in the pores of the sponge It is, in fact, a 'hydrostatic' bearing The sponge material itself, being surrounded by liquid, is pressed against the glass only by its own stiffness This is small enough to produce very little friction but still large enough to seal the cells (hydrostatic lubrication is not new, but previous arrangements have depended upon mechanical design to contain the lubricant and upon external pumps to pressurize it) The liquid pressure was measured and found to be about that required to support the load Observation, through the glass, of the working face of the sponge clearly showed the water-filled pores The movements of a particular volume of water could be traced by using dye Substantial outward seepage of the water had occurred in an hour, which seems to explain the observed increase in friction with time For purposes of comparison a sample of sponge rubber with open cells, but otherwise of about the same texture, was used This should allow much greater seepage of fluid Note (Fig 1, curve *b*) the tremendous increase in the rise of friction Lastly, to check the technique of measuring friction, a piece of closed cell sponge was tested with its cover sheets intact (Fig 1, curve *c*) This shows the high value expected for plain rubber once the wring-out of lubricant established boundary lubrication conditions

A difficulty arises if one attempts to explain animal joint lubrication by this principle The animal joint appears to involve two similar surfaces rather than a hard, impermeable surface running against the equivalent of a sponge Two sponges do not run very well against each other Suppose, however, that the sponge has a smooth, porous surface layer Because of the porosity, this layer is surrounded with liquid, and so is not pressed hard against its mating surface At the same time it is smooth enough not to become entangled with the similar layer on the other surface of the bearing The effect of porosity was demonstrated with closed-cell sponge One of the cover sheets, and the underlying cells, was perforated with a sewing needle This porous surface was run against glass using soapy water lubrication and showed much less friction (Fig 1, curve *d*) than the unperforated cover sheet (Fig 1, curve *c*)

A true animal joint model with two similar surfaces was much more difficult to imitate It was hard to find a porous material which did not have an enormous friction coefficient when rubbed against itself I found the best material to be sausage casing made from sheep intestine, lubricated with soapy water Imitation cartilage was made by stretching this over the cut-open face of closed-cell sponge Running two 'cartilages' against each other gave the result shown in Fig 2, curve *a*, where the friction coefficient starts low and rises as seepage occurs To check that trapped water is necessary, open-cell sponge was substituted for closed-cell sponge in the previous arrangement (Fig 2, curve *b*) Easy escape of the water quickly raises the friction Finally, the sponges were replaced by impervious 'Neoprene' sheets Fig 2, curve *c*, suggests that hydrostatic lubrication is occurring This is presumably because the sausage casing itself contains considerable free water

It should be pointed out that although the reasoning in this communication arrives at the permeable-surface-sponge-backed bearing as a modification of the sponge-type hydrostatic bearing, it could equally well be thought of as a bearing with a thick film of lubricant, where 'weeping' through the porous wall supplies enough liquid to maintain the film

Weeping bearings give friction coefficients as low as those in animal joints They can be made by

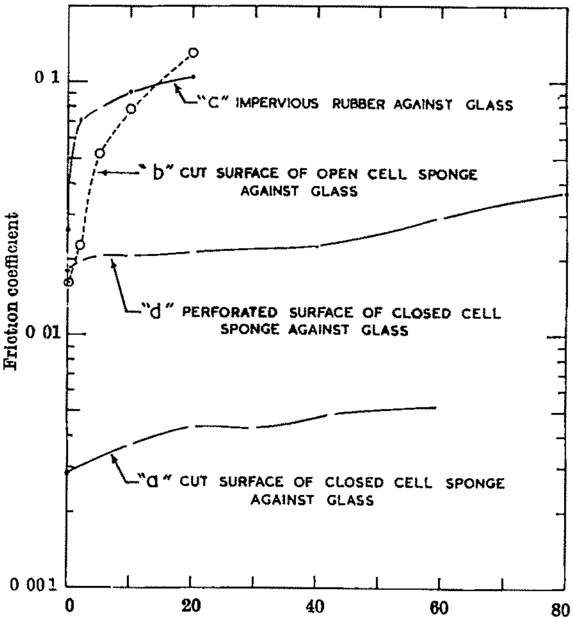

Fig 1 Friction of various surfaces against glass when lubricated with soapy water

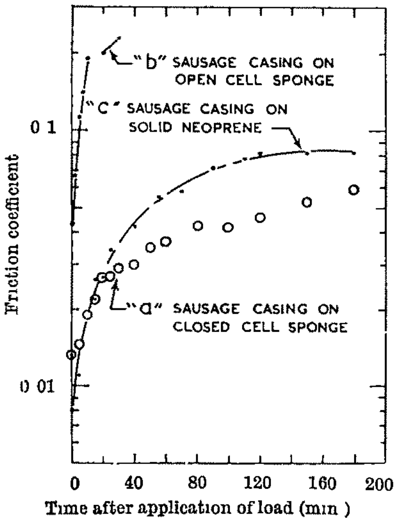

Fig 2. Friction of various types of surface against themselves when lubricated with soapy water

using surfaces and lubricants which do not give exceptionally low friction under boundary lubrication conditions (The animal-derived sausage casing used showed entirely ordinary friction coefficients once the excess lubricant had been wrung out) Animals joints could operate in this way In the following communication evidence is presented to suggest that they do

C W McCutchen

Cavendish Laboratory,
Cambridge Aug 4

[1] Charnley, J , *The New Scientist*, 6, No 138, 61 (July 9, 1959)

Experimental Evidence for Weeping Lubrication in Mammalian Joints

From existing reports[1] it is clear that the structure and mechanical properties of articular cartilage are just what are required for weeping lubrication to be possible Its outer surface is formed by a narrow layer of flattened cartilage cells and below this is a relatively acellular zone extending for some hundreds of microns down to the calcified tissue What cells there are in this zone are arranged in columns, well separated by wide areas of intercellular matrix, which probably has a structure orientated normal to the surface layer Articular cartilage is easily deformed by pressure but is very resilient, being almost perfectly elastic to intermittent pressures , and it has been suggested that this elasticity is due to exudation and re-absorption of fluid[2] Thus articular cartilage appears to resemble a rather stiff sponge, with an internal structure which would permit easy expression of fluid up to a smooth, presumably porous, outer surface

Structural evidence alone is inadequate, so a few simple experiments have been made on articular surfaces from freshly opened joints of a number of mammals Thin shavings were analysed for sodium and potassium with a flame photometer. The ratio of sodium to potassium found was of the order of 12–15 on a molar basis , so articular cartilage must contain a very high proportion of extracellular fluid, as suggested by histological preparations Exudation of only a small fraction of this total extracellular fluid would provide an adequate lubricating film That the superficial layer of flattened cartilage cells is freely permeable to small molecules is easily shown by dropping aqueous solutions of dyes on to a freshly exposed surface Dyes such as eosin, for example, rapidly penetrate to a depth of at least a hundred microns Furthermore, if excess dye is washed off, some of that which has penetrated can be re-extracted by pressing filter paper firmly against the articular surface The pore size in this superficial layer is probably quite small, since a graphite suspension with a particle size of rather less than 1μ did not appear to penetrate

If an articular surface which has been well dried with filter paper is placed against a glass slide and the point of contact examined through the glass with a microscope, fluid can be seen to exude as pressure is applied The amount of fluid exuded was estimated by placing a small piece of filter paper of known area on an articular surface and applying pressure for a brief period of time (less than a second) The sodium content of the filter paper was then measured with a flame photometer and the volume of exuded fluid calculated on the assumption that it had the same sodium content as extracellular fluid Both dry and moist filter paper were used with substantially similar results When the pressure applied was only sufficient to bring the filter paper into intimate contact with the cartilage, the amount of sodium collected was insignificant As the pressure was raised, however, the amount collected increased, and for pressures in the range to be expected in normal operation of the joint the volume of fluid exuded was calculated to be sufficient to form a layer 15–35μ thick over the area of contact Between two articulating surfaces twice as much fluid should be available, which ought to be sufficient for adequate lubrication by the mechanism suggested in the previous communication.

Weeping lubrication could equally well occur where tendons change direction (for example, the patella at the knee joint), for the cartilage surface concerned appears to have the same properties as that in the joint proper

One possible disadvantage of weeping lubrication is the occurrence of a slow outward seepage of fluid from between the apposed surfaces, which might eventually come into contact Joints seldom remain in a fixed position for very long when they are bearing a load Animals which sleep standing up, for example horses, are said always to change their position at least every half an hour, and examples are quoted in the previous communication of model bearings which retain their low friction for at least this length of time The rate of seepage would be markedly affected by the microstructure of the articular surface, but unfortunately little is known about this

It has not proved possible to devise a crucial experiment which would prove conclusively whether or not 'weeping' lubrication is an important factor in reducing joint friction Nevertheless, the evidence put forward here strongly suggests that all the necessary conditions are present , so it would be strange indeed if this type of lubrication did not in fact occur

EXPERIMENTS ON THE DEVELOPMENT OF ISOLATED BLASTOMERES OF MOUSE EGGS

By Dr ANDRZEJ K TARKOWSKI

Zoological Institute, University of Warsaw, and Mammals Research Institute,
Polish Academy of Sciences, Bialowieza

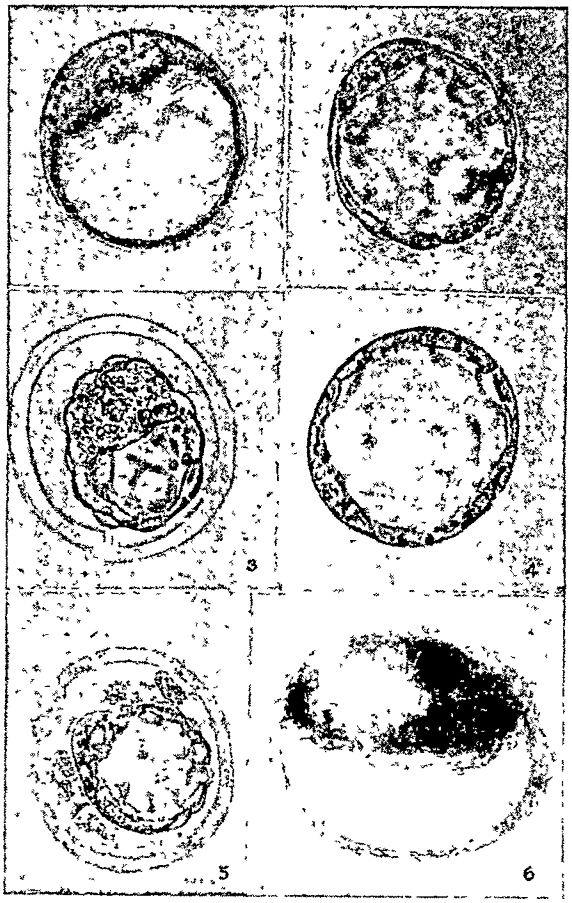
EXPERIMENTAL research on the developmental potency of blastomeres of mammalian eggs has not, so far, advanced beyond the preliminary period Nicholas and Hall[1] found that development of embryos starts to take place from both separated blastomeres of a 2-cell rat egg These embryos, although completely normal in structure, did not, however, advance beyond the egg cylinder stage, and underwent resorption before the tenth day of development Seidel[2] succeeded in obtaining two young rabbits which had developed from 2-cell eggs in which one of the blastomeres had been destroyed by piercing it with a glass needle , he did not carry out any checks of the development during pregnancy. Apart from a short note by Pincus[3], there are no reports in the literature on the development of isolated blastomeres before implantation

The investigations described below were carried out on mouse eggs, and were aimed at . (1) tracing the entire embryonic development of 'half'-embryos , and, on this basis, (2) defining the regulation capacities of 'half'-blastomeres and of the factors on which they are dependent Special attention was devoted to the structure of the blastocysts in order to ascertain to what extent the inner cell mass and trophoblast participate in their total mass Experiments were also carried out on a smaller scale on the development of 4-cell eggs of which one or three blastomeres had been destroyed

The blastomeres were destroyed under a dissecting microscope by piercing them through the zona pellucida with a glass needle fixed to a micromanipulator similar to that described by Goldacre[4] During this operation the eggs were drawn to and held against the mouth of a micro-pipette, with an outer diameter of about 40μ, the suction power of which was regulated by means of the rubber bulb attached to it All manipulations were carried out in mouse serum diluted 1 1 with normal saline Directly, or a few minutes after piercing the blastomere, it disintegrated totally or partially Using the technique previously described[5], the eggs were then transferred to the oviducts of the recipients, which had been mated the previous night with vasectomized males Animals with differing pigmentation were used as donors and recipients for the experiments, which were aimed at obtaining embryos from the second half of pregnancy or young

Development before implantation A total of about 100 'half'- and 'three-quarter'-cleaving eggs and blastocysts was obtained The volume of most 'half'- and 'three-quarter'-blastocysts is similar or only slightly smaller than that of normal blastocysts (compare Fig 1 with Figs 2 and 4) Some 'half'-blastocysts were, however, encountered lying loosely within the zona pellucida (Fig 3) The volume of the inner cell mass of 'half'-blastocysts, treated as the elliptical cap, is subject to wide variations, but in no case does it attain the smallest value found in normal blastocysts Its average size, as a percentage of the size of inner cell mass of normal 3½-day blastocysts, is 44 5 The volume of the inner cell mass of 'three-quarter'-blastocysts varies within the wide limits of variability observed for 'half'- and normal blastocysts

After carrying out observations in the living state, the blastocysts were then fixed and mounted *in toto* in order to determine the number of cells composing the inner cell mass and trophoblast The average total number of cells of 'half'- and 'three-quarter'-



(1) 3½-day normal blastocyst (× 300) (2) 'Half'-blastocyst Size equal to normal, small inner cell mass (× 300) (3) 'Half'-blastocyst lying loosely within zona pellucida (× 300) (4) 'Half'-blastocyst without differentiated inner cell mass (× 300) (5) 'Quarter'-blastocyst composed of about twenty cells Most of them form trophoblast (× 300) (6) 'Quarter'-blastocyst composed of only eight cells, six in inner cell mass and two in trophoblast Stained with hæmatoxylin, mounted *in toto* (× 750)

blastocysts was respectively 68 5 and 68 3, and number of cells of the inner cell mass is 33 0 and 58 4, again as a percentage of the number in normal 3½-day blastocysts

The numerical ratio between the cells of the inner cell mass and trophoblast varies considerably in the various 'half'- and 'three-quarter'-blastocysts Among the developing eggs there were several 'half'-blastocysts without a differentiated inner cell mass (Fig 4), and several morulas in which, despite the aggregation of a large number of cells, the differentiation of the trophoblast had not taken place

It would seem that my results are connected in a logical manner with those of cytochemical investigations by Dalcq and his co-workers on the development of the eggs of rodents[6–9] The following facts established by these authors are the most important for the interpretation of present observations · (1) the oocyte and fertilized undivided egg have a bilateral symmetry resulting from the disposition of the two cytoplasmic zones, which differ from each other cytochemically The cytoplasm of the dorsal and ventral zones passes respectively to the cells of the inner cell mass and the trophoblast (2) The plane of the first cleavage division has no established relation to the plane of symmetry of the egg

The variations in the numerical ratio between cells of the inner cell mass and the trophoblast in 'half'-blastocysts, and the variations in the volume of the inner cell mass itself, are presumably the result of variable distribution of the cytoplasm of these zones to each of the 'half'-blastomeres According to Jones-Seaton[7], there is a tendency in the ova of rats to symmetrical or oblique placing of the plane of the first division This would explain the fact that the majority of 'half'-blastocysts consist of both the inner cell mass and trophoblast, and that forms having only one of these elements are relatively rarely encountered As a result of the second cleavage division, the difference between the blastomeres, as regards the character of the cytoplasm forming them, becomes even more emphasized[7,8] The destruction of a blastomere chiefly composed of cytoplasm intended for the formation of either the inner cell mass or the trophoblast would result in wide variations in the structure of 'three-quarter'-blastocysts

A single 'quarter'-blastomere is also capable, at least in certain cases, of forming a blastocyst composed of the inner cell mass and trophoblast (Figs 5 and 6) The degree of participation of these elements in the structure of these two 'quarter'-blastocysts is, however, quite different

Since the degree of formation of the inner cell mass and trophoblast in 'half-' and 'quarter'-blastocysts is not identical with that in normal blastocysts, the regulating capacities of 'half'- and 'quarter'-blastomeres cannot be considered complete The fate of the cells which have arisen from a given blastomere must to a large extent be determined by the character of the cytoplasm forming that blastomere The fundamental factor determining the developmental potency of 'half'-blastomeres in each case would thus be the position of the first cleavage division in relation to the plane of symmetry The first two 'sister' blastomeres can, but need not necessarily, be characterized by identical capacities for further development

Development after implantation Of 175 transplanted 'half'-blastomeres, 54, or 30 8 per cent, were implanted, and 30, or 17 1 per cent, were developing normally at autopsy In actual fact the capacity of the 'half'-blastocysts to become implanted and continue development is at least twice as great, since only 50 per cent of the transplanted blastomeres are present in the genital tract of the recipients before implantation

A series of 'half'-embryos on successive days of pregnancy, from the fifth to the fifteenth, was obtained All the embryos were completely normal in structure In the period from the fifth to the tenth day their size, calculated by adding up the areas of the sections, does not exceed half the size of the normal control embryos of corresponding age The statement made by Nicholas and Hall[1] that the size of rat embryos developed from 'half'-blastomeres comes within the limits of variation of the size of normal embryos is therefore somewhat surprising In the first half of pregnancy, the rate of morphogenesis of 'half'-mouse embryos is in certain cases completely normal, and in others slightly slowed down Delay in reaching the successive stages never exceeds 24 hr and most often is considerably less

Two periods of intensified resorption of 'half'-embryos may be noted—one immediately following implantation, and the other at the beginning of the second half of pregnancy, about the eleventh day On the eleventh day certain 'half'-embryos reach the stage and size characteristic of normal development , others correspond to tenth-day normal embryos Dead embryos are also encountered From the twelfth day on, the number of resorbed embryos increases markedly On the other hand, all the surviving embryos are already at the same stage of development and of the same size as the normal ones Rapid increase in the rate of development of 'half'-embryos, which takes place at this time, seems to be caused by two factors (1) real increase in the rate of growth connected with the beginning of functioning of the chorio-allantoic placenta, (2) apparent hastening of development due to elimination of most retarded embryos by resorption

Since all the embryos undergo normal development until the eleventh day, and complete regulation may be said to have taken place, resorption must be only the result of disturbance of the normal relations between mother and embryo, connected with considerable retardation in the rate of development

In view of my observations it seems that resorption of all 'half'-rat embryos during the first half of pregnancy, reported by Nicholas and Hall[1], had been caused to a large extent by improper experimental technique

Three females gave birth to young which had developed from 'half'-blastomeres (first female, 1 young one after 20 days , second female, 2 young ones after 19 days , third female, 3 young ones after 20 days) These young comprised four females and two males All the animals were fertile, and each female gave birth to several litters No abnormalities of the kind described by Seidel[2] or elsewhere were found in the young or in the more advanced embryos

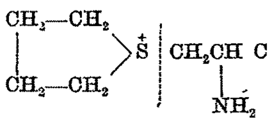
METABOLIC AND CHEMICAL STUDIES OF 'MYLERAN': FORMATION OF 3-HYDROXYTETRAHYDROTHIOPHENE-1,1-DIOXIDE *IN VIVO*, AND REACTIONS WITH THIOLS *IN VITRO*

By Dr J J. ROBERTS and Dr G P WARWICK
Chester Beatty Research Institute, Institute of Cancer Research, Royal Cancer Hospital, London, S W 3

IT has been reported recently[1] that the S-β-alanyl-tetrahydrothiophenium cation (I) is formed by the reaction of dimethanesulphonyloxybutane ('Myleran') with cysteine This compound is labile under a variety of conditions, decomposing to tetrahydrothiophene, in which the sulphur atom has been derived from the cysteinyl moiety Thus treatment with mild alkali (pH 8–9), electrolysis of its aqueous solution, or pyrolysis at 140° C lead to a nearly quantitative conversion into tetrahydrothiophene



(I)

Since rats which had received injections of either 2,3-^{14}C-'Myleran' (prepared by Dr P Brookes) or the corresponding labelled sulphonium compound (I) excreted the same major urinary metabolite, it seemed very likely that intermediate formation of a sulphonium compound of this type occurred also *in vivo* after injection of 'Myleran' On the basis of the *in vitro* findings which demonstrated the lability of the sulphonium compound and the course of its decomposition, it was suggested that the major urinary metabolite was a derivative of tetrahydrothiophene This has now been established, since injection into a rat of ^{35}S-tetrahydrothiophene (II) again led to the excretion of only one major metabolite, identical with that formed from 'Myleran' and the sulphonium compound as judged by its chemical properties, and its R_F value in several solvent systems It was thus further evident that the metabolite contained a sulphur atom The fact that it failed to give a positive test for sulphur on paper chromatograms suggested that one of the changes which had occurred involved oxidation of the sulphur atom ^{35}S-Tetrahydrothiophene-1,1-dioxide (III), a likely product of oxidation *in vivo*, was therefore synthesized and shown to be converted in the rat into one major urinary metabolite which differed in R_F value from the parent dioxide, but which was again identical with that formed from 'Myleran', the sulphonium compound, and tetrahydrothiophene

Possible pathways for the metabolism of tetrahydrothiophene-1,1-dioxide included reduction of the sulphone group, further oxidation, or ring substitution It seemed improbable that reduction was involved in view of the marked stability of the sulphone group to reduction *in vitro* Further oxidation of the tetrahydrothiophene-1,1-dioxide could result in unsaturation of the ring, the formation of a ketone, or fission to a di-acid It was concluded that these changes had not occurred as the metabolite was unaltered by treatment with bromine or warm neutral permanganate, was unreactive towards dinitrophenylhydrazine, and was neutral as shown by passage through columns of ion exchange resins However, ring substitution by hydroxylation was considered possible, particularly in view of the enhancement of the reactivity of the ring carbon atoms towards nucleophilic reagents by the powerfully negative sulphone group The presence in the metabolite of one or more hydroxyl groups was demonstrated by its reactivity towards acetyl chloride, or benzoyl chloride in pyridine, leading to the formation of new compounds from which the metabolite could be regenerated by hydrolysis with mineral acid

Injection of necessarily small quantities of 'Myleran' into a rat had hitherto precluded isolation of the metabolite in a pure state and in quantities sufficient to isolate a derivative , but with the knowledge that tetrahydrothiophene-1,1-dioxide, a non-toxic compound, gave rise to the same major urinary metabolite, this difficulty was overcome Moreover, it was demonstrated that the same metabolite was excreted by the rabbit after injection of ^{14}C-'Myleran' or ^{35}S-tetrahydrothiophene-1,1-dioxide Large doses of tetrahydrothiophene-1,1-dioxide with a radioactive carrier were injected into rabbits, and after extraction of the urinary metabolite into chloroform

(IV) (III) (II)

the residual oil was treated with 3,5-dinitrobenzoyl chloride The resulting ester was recrystallized to constant specific radioactivity from methanol, and formed almost colourless prisms, melting point 195–197° C

Analysis $C_{11}H_{10}O_8N_2S$ requires
$C = 40\ 0$, $H = 3\ 0$, $N = 8\ 5$, $S = 9\ 7$, m w $= 330$
Found $C = 40\ 5$, $H = 3\ 2$, $N = 8\ 3$, $S = 9\ 4$, m w $= 340$

This same radioactive ester was prepared from the combined chloroform extracts of the urine obtained from two rabbits, one of which had received a small dose of ^{14}C-'Myleran' to act as carrier, and the other a relatively large quantity of tetrahydrothiophene-1,1-dioxide to enable separation of the derivative It was also obtained from the chloroform extract of urine from rats injected with high doses of the S-β-alanyl-tetrahydrothiophenium salt (I) containing a radioactive tracer Each derivative had melting point 195–197° C alone, and on admixture

The foregoing experiments indicate that the urinary metabolite formed from 'Myleran' is monohydroxy-tetrahydrothiophene-1,1-dioxide (IV) 2-Hydroxytetrahydrothiophene-1,1-dioxide, prepared via the 2-bromo compound[2] from radioactive tetrahydrothiophene-1,1-dioxide, was shown to possess a different R_F value from the metabolite However, the 3,5-dinitrobenzoate of an authentic sample of 3-hydroxytetrahydrothiophene-1,1-dioxide (IV) (sulpholanol), kindly supplied to us by Prof E Boyland, had melting point 195–197° C which was undepressed on admixture with the 3,5-dinitrobenzoate formed from the 'Myleran' metabolite

The metabolism of 'Myleran' in the rat and the rabbit may be represented in the accompanying scheme

In connexion with the possible mode of action of 'Myleran' it was of interest to determine whether the tetrahydrothiophene formed from the drug *in vivo* could have been derived by reaction with the thiol group of peptides such as glutathione, or with larger molecules such as proteins It has been shown that 'Myleran' reacts smoothly with the thiol group of glutathione in an alkaline medium forming tetrahydrothiophene, characterized as its mercurichloride Similarly, thiol-containing proteins such as denatured egg albumin and reduced keratin have been shown to yield tetrahydrothiophene when treated with 'Myleran' in an alkaline medium, indicating that sulphonium ion formation is not restricted to compounds of low molecular weight

This novel 'dethiolation reaction' provides additional evidence to the *in vivo* findings in support of the view that reactions of this type may be responsible for some of the diverse pharmacological properties of the bifunctional alkylating agents Sulphonium ion formation might lead to a modification of the function of certain proteins, but in addition dethiolation could conceivably have more far-reaching effects by actually altering the sequence of amino-acids in a peptide or protein chain It is hoped that work on these aspects may be continued

Full details of this work will be published elsewhere

The work has been supported by grants to the Chester Beatty Research Institute (Institute of Cancer Research Royal Cancer Hospital), from the British Empire Cancer Campaign, the Jane Coffin Childs Memorial Fund for Medical Research, the Anna Fuller Fund and the National Cancer Institute of the National Institutes of Health, U S Public Health Service

We wish to thank Prof A Haddow and Dr L A Elson for their interest in the work, and to record our appreciation for helpful discussion with many of our colleagues We gratefully acknowledge technical assistance from Miss M Morton

REGISTRATION OF THE SPERMICIDAL EFFECTS OF DIOCTYL SODIUM SULPHOSUCCINATE

By Prof PER ERIC LINDAHL and KJELL WEDIN
Institute of Zoophysiology, University of Uppsala

STUDIES of the kinetics of spermicidal effects are not possible without a method for the estimation of the proportion of living spermatozoa at a given time This implies that the time required for this estimation has to be very short in relation to the period of time during which the process is to be studied By working with dark-field illumination, and using comparatively long photographic exposures, different pictures of the lucid spermatozoa, either immobile or in different kinds of movements, are obtained

For the present investigation bull spermatozoa were chiefly used Some experiments, however, were performed with human sperm cells, with identical results A buffered egg-yolk extract was used as an optically suitable diluent for the semen and the spermicidal substance[1] The optical equipment consists of a Zeiss microscope with dark-field condenser, heating stage, plane-apochromatic objective (× 10), compensating plane eyepiece (× 8), and a Zeiss carbon arc-lamp for microscope use The microscope carries a Leica camera, somewhat modified in order to facilitate a fast winding-on of the film Using the Kodak film 'Tri-*X*', 1 0 sec is found to be an appropriate time of exposure Prints of the negatives are enlarged five times The final linear enlargement is thus 400 times

For each determination of the percentage of mobile spermatozoa two exposures are made with an interval of 1 0 sec On the first picture the moving spermatozoa leave tracks according to their different ways of moving A comparison between the first and the second picture in a pair reveals whether doubtful cases depend upon passive motions induced by other spermatozoa or upon active movements It also renders possible classification of cells disappearing by swimming in the direction of the optical axes as moving

When performed with all precautions two counts on the same sample generally do not differ by more than 1 5 per cent All the operations described below are performed at 37° C with materials which have been preheated to this temperature Of the semen, diluted to give about 20,000 spermatozoa/μl, that is,

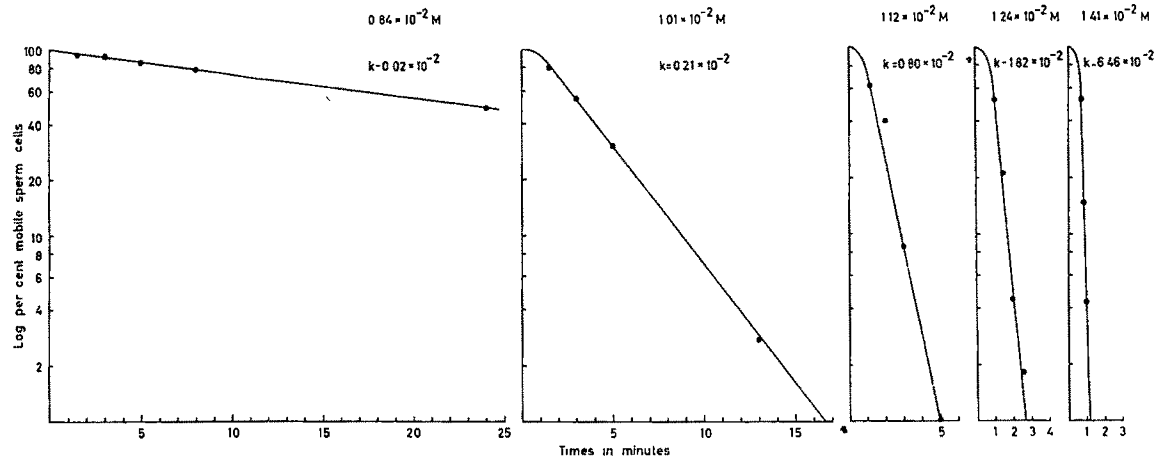

Fig 1 Semi-log plot of percentage of mobile sperm cells versus time in minutes at different concentrations of dioctyl sodium sulphosuccinate k, Apparent death-rate constant

twice the final density wanted, 0 5 ml is brought into a thick-walled test-tube provided with a rod-shaped magnetic stirrer The tube is placed in a rotating (180 r p m) magnetic field and 0 5 ml of a solution of the spermicidal substance in diluent (twice the concentration to be studied) is added, all statements as to time being related to this moment as zero About 10 µl of this mixture are put on a slide, and a coverglass provided with a fine rim of 'Vaseline' along its edges is placed on the drop in such a way that no air bubbles are left between the two glasses The preparation is thus protected from evaporation, aerobiosis being, however, permitted only for limited periods of time The first exposures are made after 60 and 61 sec , and are followed by two exposures every fifteenth and thirtieth second

A stock solution of dioctyl sodium sulphosuccinate in acetone (0 45 *M*, 20 per cent) is prepared and added to the diluent The highest final concentration of acetone in our experiments was about 5 per cent In control experiments this concentration had no effect on the percentage of mobile spermatozoa for periods of up to 2 hr

Concentrations of dioctyl sodium sulphosuccinate ranging from 0 84 × 10^{-2} *M* to 1 41 × 10^{-2} *M* (0 38 per cent to 0 63 per cent) give exponential death-rate curves that are more easily read in logarithmic form (Fig 1) As in corresponding experiments with bactericidals[2] these straight curves permit the calculation of 'apparent death-rate constants' The analytical plotting of the relation between concentration of dioctyl sodium sulphosuccinate and the apparent death-rate constants is seen in Fig 2 According to the theoretical analyses given by Johnson, Eyring and Polissar[3], these curves may give considerable information about the mechanism involved Tentatively we have transformed their expression

$$\pi = 1 - p^{m} = 1 - (1 - e^{-kt})^{m}$$

into

$$\log (1 - \pi) = m \log (1 - e^{-\lambda t})$$

and plotted log $(1 - \pi)$ against log $(1 - e^{\lambda t})$ choosing such a value of k as to give a straight line (Fig 3) This implies identical values of m and n With decreasing concentrations of dioctyl sodium sulphosuccinate both k and n decrease Log n plotted against log concentration gives a linear relationship As the concentration of the spermicide is large it remains in excess, and may thus be considered

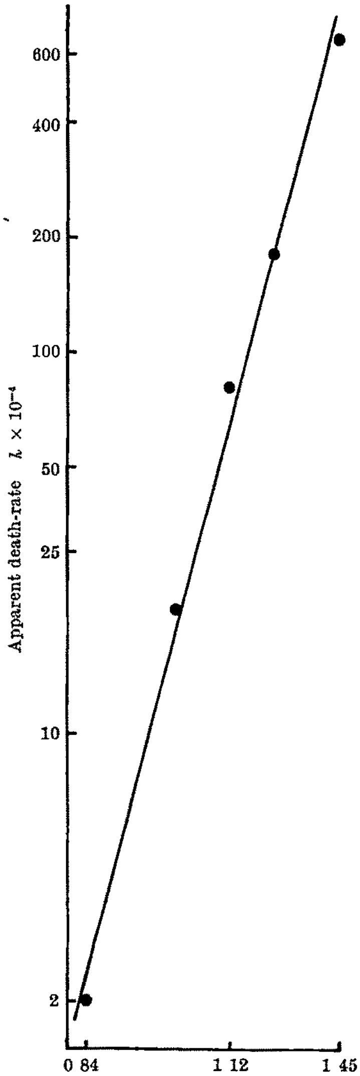

Fig 2 Log-log plot of the apparent death-rate constant versus different concentrations of dioctyl sodium sulphosuccinate

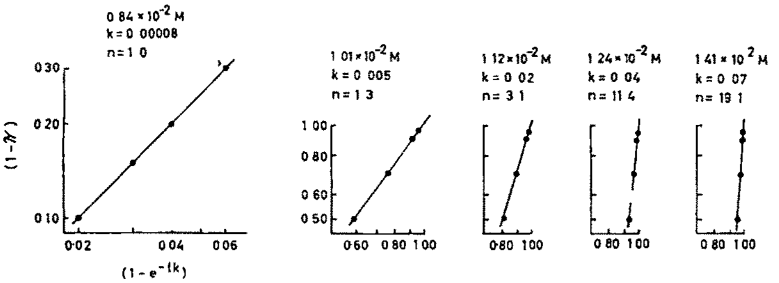

Fig. 3. Log–log plot of $(1 - \pi)$ versus $(1 - e^{-kt})$ at different concentrations of dioctyl sodium sulphosuccinate

constant[2]. According to Johnson, Eyring and Polissar *n* may thus represent the number of molecules of dioctyl sodium sulphosuccinate combining with each molecule of protein in the cells. Occasionally curves relating log surviving sperm cells to time obtained with low concentrations $(0.84 \times 10^{-2} M)$ of dioctyl sodium sulphosuccinate show a sharp break, the death-rate suddenly decreasing. This observation will be further analysed. The effects on the relationships described of anaerobiosis, temperature and ageing of the cells are being studied.

Corresponding results have been obtained with chloramin-*T* and hydrogen peroxide.

GLUCOSE-6-PHOSPHATE DEHYDROGENASE AND HUMAN ERYTHROCYTES

Characteristics of Glucose-6-Phosphate Dehydrogenase from Normal and Primaquine-sensitive Erythrocytes

RECENT developments have emphasized the fact that genes may express themselves in terms of qualitative alterations of such macromolecules as human hæmoglobins[1] and blood-group substances[2]. Whether or not such qualitative differences at the level of the enzyme usually account for the inherited enzymic deficiencies is not known, but some instances of qualitative alterations in enzymes have been reported. Immunochemical evidence[3] exists for an inactive enzyme-like molecule in mutants lacking tryptophan-synthetase. Qualitative differences in glutamic dehydrogenase have been found in mutants of *Neurospora*[4]. An opportunity exists to explore this possibility further in the case of primaquine-sensitive hæmolytic anæmia[5], an inherited defect in which the erythrocytes of affected hemizygous or homozygous persons have only 5–20 per cent of the normal activity of glucose-6-phosphate dehydrogenase.

In order to investigate possible qualitative or quantitative differences between the glucose-6-phosphate dehydrogenase in primaquine-sensitive and normal erythrocytes, a method of partially purifying the enzyme has been developed[6,7] and preliminary comparative studies have been made. The partially purified preparation is hæmoglobin-free and represents a 60- to 80-fold purification of glucose-6-phosphate dehydrogenase in 20–50 per cent yield, with little or no contamination with 6-phosphogluconic dehydrogenase. The enzyme was assayed in final concentrations of 0.1 *M tris* buffer, *p*H 8.0, 0.01 *M* magnesium chloride, 2×10^{-4} *M* triphosphopyridine nucleotide, and 6.0×10^{-4} *M* glucose-6-phosphate, by observing the increase in optical density at 340 mμ or by measuring the 450 mμ fluorescence in a photofluorometer, using 360 mμ exciting light. Within an accuracy of ± 5–20 per cent, the preparation from both a primaquine-sensitive male and a normal male control had Michaelis constants of 2.1×10^{-6}, 3.9×10^{-5}, and 6.9×10^{-4} *M* for triphosphopyridine nucleotide, glucose-6-phosphate, and 2-deoxyglucose-6-phosphate, respectively. Both utilized the last substrate at 9 per cent of the maximum rate for glucose-6-phosphate. In a mixed buffer which was 0.05 *M* each in phosphate, *tris* and glycine, both preparations had the same *p*H-optimum curve from *p*H 6.0 to 10.0. Heat of activation (20–40° C.) was found to be 9.5×10^3 cal./mole for both preparations. Similar movement on anion-exchange column chromatography has been observed for the enzyme from both sources[7]. The percentage yield of activity for the enzyme from sensitive cells remained approximately the same as that for normal cells throughout the partial purification and all experiments. Similar labilities and the stabilizing effect of triphosphopyridine nucleotide have been reported[6]. The latter may be related to the inactivation of this enzyme by erythrocytic stroma, which has been observed by others (ref. 8 and following communication).

Because of the many identical catalytic parameters, it seems unlikely at the present time that the greatly reduced activity of erythrocytic glucose-6-phosphate dehydrogenase in these persons is due to a qualitative difference at the catalytic site of the enzyme, if a qualitative difference exists at all. We are left, therefore, with the necessity of considering a gene which manifests itself through decreasing the rate of synthesis or increasing the rate of inactivation of this enzyme. The fact that the 80-fold purified preparation can be far more extensively purified indicates that the glucose-6-phosphate dehydrogenase constitutes only a very minute portion of the hæmoglobin-free proteins and emphasizes the necessity and opportunity for more definitive comparisons of relatively pure preparations of glucose-6-phosphate dehydrogenase. Some differences in labilities[8,9] and *p*H optima[9] between this enzyme in normal and primaquine-sensitive hæmolysates have been reported. In view of the extensive contaminations with other proteins and the stabilizing effect of small amounts of various substances[6], caution should be taken in drawing inferences as to molecular differences based on differences in lability of the glucose-6-phosphate dehydrogenase between normal and primaquine-sensitive hæmolysates and crude preparations

Mechanism of Inactivation of Glucose-6-phosphate Dehydrogenase in Human Erythrocytes

IN the course of investigation of primaquine-sensitive hæmolysis we found that glucose-6-phosphate dehydrogenase is inactivated by incubation with stromata in hæmolysates of primaquine-sensitive and non-sensitive erythrocytes alike[1,2] Purified hæmoglobin-free glucose-6-phosphate dehydrogenase from both kinds of erythrocytes appears qualitatively identical and is highly stabilized by triphosphopyridine nucleotide[3]

We wish to report that in hæmolysates of both types of cells 'Norit' inactivates glucose-6-phosphate dehydrogenase by adsorption of pyridine nucleotides[4] as do stromata by pyridine nucleotidase activity Inactivation of glucose-6-phosphate dehydrogenase by stromata is prevented by triphosphopyridine nucleotide, diphosphopyridine nucleotide and nicotinamide Inactivation by 'Norit' in stroma-free hæmolysates is prevented by tri- and di-phosphopyridine nucleotide but not by nicotinamide Dialysed stroma-free hæmolysates retain bound coenzyme and, in them, glucose-6-phosphate dehydrogenase is not inactivated by incubation unless stromata or 'Norit' is added Glucose-6-phosphate dehydrogenase inactivation and removal of bound coenzyme occur concomitantly during incubation with stromata or 'Norit'

Human erythrocytes washed with cold 0 145 *M* sodium chloride were hæmolysed by rapid freezing and thawing The hæmolysate was diluted with four or five volumes of cold water , the stromata were removed by centrifuging for 60 min at 28,000*g*, 0° C either before or after incubation After dialysis (usually overnight) in 0 067 *M* phosphate buffer, *p*H 7 4, the hæmolysates were assayed for glucose-6-phosphate dehydrogenase and 6-phosphogluconic dehydrogenase activity by a modification of the coupled reactions with glutathione reductase previously described[1] In a final volume of 7 0 ml the complete reaction mixtures contained : (1) *tris*-hydroxymethylaminomethane, $5 \times 10^{-4} M$, adjusted to *p*H 7 4 with hydrochloric acid , (2) ethylenediamine tetraacetic acid adjusted to *p*H 7 4 with sodium hydroxide, $5 \times 10^{-5} M$, (3) triphosphopyridine nucleotide (Sigma), $7 \times 10^{-8} M$, (4) oxidized glutathione, GSSG (Schwarz), $5 \times 10^{-6} M$; (5) glucose-6-phosphate (Sigma), $4 \times 10^{-6} M$ for glucose-6-phosphate dehydrogenase , or (6) 6-phosphogluconate (Sigma), $4 \times 10^{-6} M$ for 6-phosphogluconic dehydrogenase , and (7) varying amounts of hæmolysate as shown in Fig 1 Reactions were run for 15 min at 37° C , *p*H 7 4

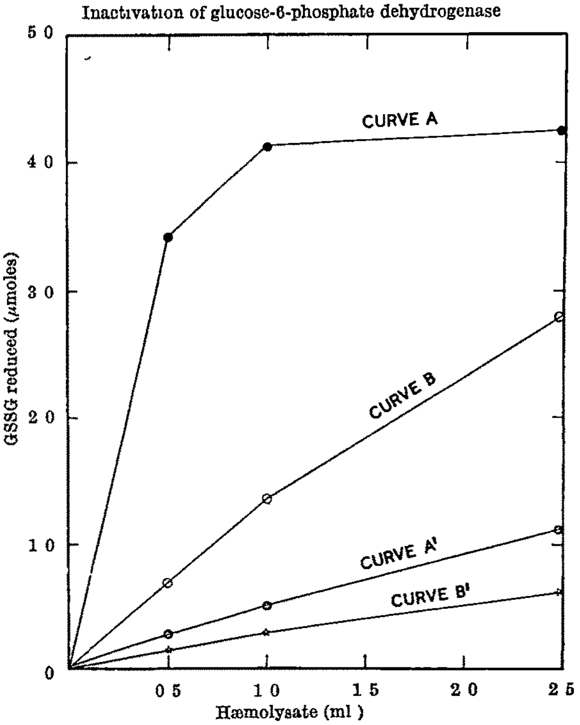

Fig 1

Fig 1 shows representative results from a male non-sensitive (*A*, *A'*) and a male sensitive individual (*B*, *B'*) Curves *A* and *B* represent activity of glucose-6-phosphate dehydrogenase in dialysed hæmolysates from which stromata had been removed immediately after hæmolysis Curves *A'* and *B'* show activity of glucose-6-phosphate dehydrogenase, after incubation of hæmolysate from non-sensitive cells for 1 hr at 45° C and from sensitive cells for 1 hr at 37° C , prior to removal of stromata Addition of tri- or di-phosphopyridine nucleotide ($10^{-4} M$) to these hæmolysates before incubation provided 100 and 73 per cent protection, respectively, based on approximate integration of the curves obtained Nicotinamide ($5 \times 10^{-3} M$) provided protection ranging from 15 to 60 per cent in non-sensitive and 60 to 100 per cent in sensitive hæmolysates

Similar incubation of doubly centrifuged stroma-free hæmolysates results in little or no inactivation either before or after dialysis However, glucose-6-phosphate dehydrogenase is inactivated in stroma-free hæmolysate by incubation with acid-washed 'Norit' (2 5–30 mgm per ml) or by incubation after removal of 'Norit' Triphosphopyridine nucleotide completely protected glucose-6-phosphate dehydrogenase in stroma-free hæmolysates incubated after removal of 'Norit' Diphosphopyridine nucleotide protected it in non-sensitive hæmolysates by 47 per cent and in sensitive hæmolysates by 91 per cent However, nicotinamide gave no protection, suggesting that its effect occurs by inhibition of stroma factor, whereas tri- and di-phosphopyridine nucleotide stabilize the enzyme itself

Glutathione reductase and 6-phosphogluconic dehydrogenase in hæmolysates, unlike glucose-6-phosphate dehydrogenase, remain active even after incubation with stromata or 'Norit' This allows preliminary investigation of the binding of triphosphopyridine nucleotide to glucose-6-phosphate dehydrogenase because the former is also the coenzyme of 6-phosphogluconic dehydrogenase Stroma-free dialysed hæmolysates retain sufficient triphosphopyridine nucleotide for the hæmolysate to reduce GSSG in 1 hr at 37° C when 6-phosphogluconate, but not triphosphopyridine nucleotide, is added to the reaction mixture However, under the same conditions, GSSG is not reduced after incubation with stromata or 'Norit' (Triphosphopyridine nucleotide is retained in hæmolysate which has been dialysed for as long as 42 hr)

The inactivation of glucose-6-phosphate dehydrogenase and loss of triphosphopyridine nucleotide remaining in dialysed hæmolysates occur together, suggesting that the non-dialysed fraction of triphosphopyridine nucleotide is bound to glucose-6-phosphate dehydrogenase and that this is active only when bound with its coenzyme The 6-phosphogluconic dehydrogenase does not bind triphosphopyridine nucleotide or require it for stabilization

Intact human erythrocytes have pyridine nucleotidase activity, both on the surface and within the cell the surface activity is demonstrated by the inactivation of glucose-6-phosphate dehydrogenase in isotonic hæmolysates during incubation with whole human erythrocytes , the intracellular effect is shown by a loss of glucose-6-phosphate dehydrogenase activity and bound triphosphopyridine nucleotide in erythrocytes incubated in isotonic saline for 2 hr at 45° C Although no loss of glucose-6-phosphate dehydrogenase activity occurred during storage of non-sensitive blood, gradual loss of glucose-6-phosphate dehydrogenase activity in sensitive blood during four weeks of storage in acid–citrate–dextrose solution also suggests an intracellular action of pyridine nucleotidase

These results show that triphosphopyridine nucleotide stabilizes glucose-6-phosphate dehydrogenase in hæmolysates as well as in partially purified preparations and confirm the suggestion that this stabilization may be related to the inactivation of this enzyme by erythrocytic stroma (ref 5 and previous communication) Partial stabilization of glucose-6-phosphate dehydrogenase by nicotinamide is indirect, by protection of the pyridine nucleotides from pyridine nucleotidase activity of stromata Stabilization by diphosphopyridine nucleotide may also be indirect, by its enzymatic conversion to triphosphopyridine nucleotide, since diphosphopyridine nucleotide does not stabilize glucose-6-phosphate dehydrogenase of partially purified preparations[5] Nevertheless, protection of glucose-6-phosphate dehydrogenase of stroma-free hæmolysates by di- as well as triphosphopyridine nucleotide indicates that the former can help to stabilize glucose-6-phosphate dehydrogenase in human erythrocytes, even though it is not a coenzyme for it The key to the mechanism of primaquine hæmolysis, and possibly of cellular ageing, may be related to these stabilizing processes

X-RAY DAMAGE AND RECOVERY IN MAMMALIAN CELLS IN CULTURE

By M. M. ELKIND and HARRIET SUTTON

National Institutes of Health, U S Public Health Service, Bethesda 14, Maryland

As measured by the ability to sustain unlimited proliferation, the X-ray sensitivity of micro-organisms has been generally observed to be much greater than the sensitivity of important macromolecules This, in itself, has been an important reason for associating the lethal effect of X-rays with the genetic apparatus of the cell Puck and Marcus's[1] observation that mammalian cells in tissue culture were even more sensitive—10–100 times or more—than bacteria or yeasts further reinforced this view and led to their very reasonable proposal that the sensitive sites in mammalian cells are the chromosomes

If the functional integrity of the genetic apparatus is required for viability, since the survival curves of most somatic cells are sigmoid (or multihit), it might be expected that survivors after X-irradiation would be more sensitive to subsequent exposure than the parental population This follows from the fact that multihitness implies a threshold type of response (which means damage must be accumulated before an effect is observed) and hence that surviving cells accumulated a sublethal amount of damage

We have investigated the question of the presence of heritable damage in two cell lines of the Chinese hamster, *Cricetulus griseus*[2] (clone *A* ovarian tissue and strain *V* female lung tissue), propagated in tissue culture We have found that essentially all the survivors after X-irradiation did not display heritable damage, as would be evidenced by their radiosensitivity, but rather that they repaired their accumulated damage before their first division after irradiation

Our growth medium bears the designation *HU*-15 It consists of Eagles's amino-acids and vitamins[3] with glutamine at a concentration of 1 m*M* ; 4 per

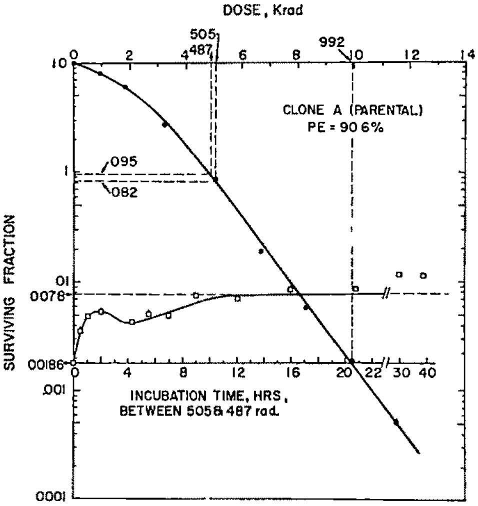

Fig. 1. Recovery of X-irradiated cells (between 505 rad and 487 rad doses) as a function of time of incubation at 37° C

cent Earle's *NCTC*-109 [4], Puck's[5] saline *F* with the calcium content increased 6.5 times, and 15 per cent undialysed fœtal calf serum (Colorado Serum Co., Denver). Both cell lines grow in this medium with a doubling time of about 12 hr.

Our X-ray source consisted of a Machlett *OEG*-60 tube powered by a full-wave rectified, 55 kV supply. The tube was operated at 12 m.amp. with 0.175 mm. aluminium filtration, absorbed dose-rate 720 rads/min. After the attachment of cells in 9-cm. Petri dishes, the plate covers and growth medium were removed and the cells were irradiated at room temperature in a humidified atmosphere of 2 per cent carbon dioxide in air. Surviving clones were stained and counted after 12–18 days incubation at 37° C in a 2 per cent carbon dioxide incubator. Identification of abortive colonies was facilitated by the use of a projection technique, although our results are essentially the same whether or not abortive colonies are included. Plating efficiencies in most of our experiments were about 70 per cent; essentially the same results were obtained, however, in experiments having plating efficiencies from 10 to 90 per cent.

In discussing the observations, a multihit model will be assumed for simplicity although our conclusions apply equally as well to sigmoid or threshold type survival curves in general. For lag-phase cells, clone *A* was found to display hitness numbers of 4–5 and clone *V* 6–7.

X-ray dose fractionation was employed to test for repair of accumulated damage. Fig. 1 shows a survival curve for single clone *A* cells trypsonized and plated 2 hr. before exposure. (Standard errors are indicated where larger than the plotted points.) In addition, the lower portion of the figure shows a recovery curve for cells which had received a first dose, 505 rads, followed by incubation at 37° C for various periods of time before receiving a second dose of 487 rads.

If there had been no recovery between the exposures, the two doses would have been completely additive, and the survival after a total of 992 rads would have been 0.0019. Alternatively, if there had been complete recovery between doses, the survival to the first and second doses would have been 0.082 and 0.095, respectively. The product of these latter values is 0.0078, which represents the survival corresponding to complete recovery between doses. The points to be noted are: (1) as a function of time at 37° C., the cells recover in a manner which may involve repair of sites as well as fluctuations in sensitivity; (2) for clone *A* cells, recovery appears to be complete by about 10 hr. and constant until about 25 hr.; and (3) the survival rises above 0.0078 after about 25 hr., which probably represents the effect of cellular multiplicity on survival concomitant with the onset of post-irradiation division.

The likelihood of the last point was arrived at by two types of measurements. First, we showed that the 'principle of cellular multiplicity' holds for these cells. That is, the surviving fraction of colonies containing more than one cell is shifted upward by an amount governed by the average cellular multiplicity providing that each cell in the colony has the same average sensitivity and that it must be inactivated independently to suppress post-irradiation colony formation. Secondly, an estimate of division delay following a first dose of 505 rads was made by comparing the clonal growth of irradiated cells with unirradiated controls. The comparison was made after clones had reached a size, about 100 cells per clone, which permitted an unambiguous identification of such clones as survivors. In agreement with the recovery curve in Fig. 1, the latter measurement indicated a division delay of about 30 hr.

In addition to the preceding, we have also shown that recovery can take place at room temperature unaccompanied by division in the control population.

To verify that the plateau region in the recovery curve of Fig. 1 represents complete repair of the accumulated damage resulting from the first dose, the survival curve was repeated after 505 rads followed by 18.1 hr. at 37° C. In Fig. 2, the non-fractionated survival curve was re-drawn starting from the survival corresponding to a first dose of 505 rads. The figure displays an excellent fit of the re-drawn curve to the observed points and shows that, in the exponential regions of both curves, maximum recovery shifts the survival upward by a factor equal to the hitness number. It also follows from Fig. 2 that, at least in the region of full recovery, synergism between the first and second doses is probably absent and therefore the second dose measures the degree of repair of damage resulting from the first dose.

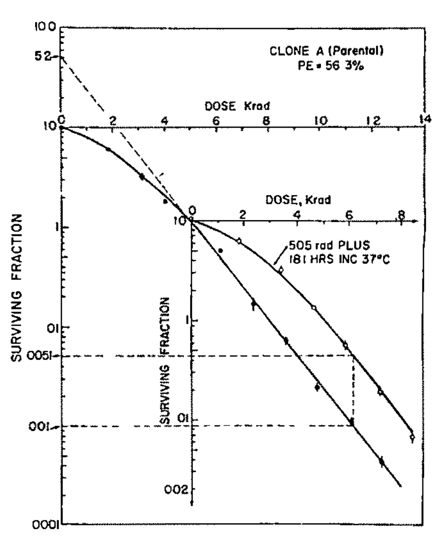

Fig. 2. Full recovery after a dose of 505 rads followed by 18.1 hr. at 37° C. as evidenced by the repetition of the non-fractionated survival curve

The preceding figures are part of a comprehensive study which will be reported in detail elsewhere To the extent that these and the results to be reported are typical for somatic cells in general, it should be noted that (1) The vast majority of surviving cells completely repair their accumulated damage before their first division post-irradiation This means that if the hitness number is n, in the exponential region, survivors undo the effects of a maximum number of hits which is $n-1$ (2) The kinetics of recovery depend on the physiological state of the cells and/or can be caused to appear to undergo large oscillations depending on the recovery medium These apparent oscillations may result from the combined effects of changes in sensitivity and repair of inactivated sites (3) Although there are important quantitative differences, log-phase cells respond similarly (4) A cell can undergo repeated cycles of damage and repair with no apparent attenuation of the repair process(es)

There are several contexts in which these findings are of interest If the chromosomes are the X-ray sensitive sites and chromosome breaks are the hits leading to lethality, then some new properties of restitution must be considered First, restitution goes to completion in surviving cells Secondly, the cell's ability to restitute breaks remains unimpaired after repeated doses In view of the preceding, Puck's[6] report of a high yield of mutant characteristics in the progeny of cells surviving 5–7 mean lethal doses may be applicable to the material he was using , may be evidence of a radiation-induced chromosomal lability which is expressed after recovery and during clonal growth , may imply that mutation production and lethality are not, in general, closely connected , or may indicate that the chromosomes are not the primary sensitive sites related to viability

Another area in which these results may apply is in connexion with tumour therapy Treatment protocols involving fractionation are common, permitting, in general, ample time between treatments for considerable if not complete recovery Even for situations in which the hitness number may only be 2, a simple calculation reveals that, if recovery is not duly accounted for, the survival using fractionation can be higher than expected by several orders of magnitude Of course, tissue recovery in a general sense has been recognized by radiation therapists for a long time These results, however, provide a cellular basis for this phenomenon and lend specific direction to the research that should be undertaken both to take advantage of, as well as to control, this effect

Additional experiments are planned (or in progress) to examine the influence of dose-rate on survival, and the biochemical and cytogenetic aspects of recovery

We are indebted to Dr T T Puck for a sample of his clone *A*, ovarian tissue, which has been propagated in our laboratory without recloning since August 1958 , to Dr Denys Ford for his *V* strain, female lung tissue, which was recloned in December 1958 ; and to Dr George Yerganian, who supplied the Chinese hamsters for the original explants

TALLOWY DISCOLORATION IN CHEDDAR CHEESE

By STAFF OF THE WALLACEVILLE DAIRY LABORATORY
Wellington, New Zealand

Fat Oxidation and Trace Metals in Cheese

A SERIOUS fault in mature Cheddar cheese is the gradual appearance of bleached areas with a tallowy flavour, aptly described as 'tallowy discoloration' or 'white streak' The erratic incidence of this defect has for long hindered efforts to find the prime cause In seeking the cause, most of the chemical features examined showed little, if any, difference between normal and tallowy portions, apart from the oxidized condition of the latter The most striking differences were found in the disposition of trace metals As compared with adjacent normal cheese the copper content of the centre of tallowy portions was always much lower, often as little as a third , but the iron content was always higher, usually by about a half Experiments with threefold added copper did not affect the incidence of the tallowy defect, nor did added iron salts

When normal cheese curd was treated with an excess of warm 5 per cent iron-free brine, the portion that dissolved contained more iron than the undissolved cheese, which was shown to lose a corresponding quantity of iron Moreover, treatment for a shorter period so that less cheese dissolved, resulted in a higher iron content of the dissolved cheese This indicated the presence of an iron compound more soluble than the cheese, and also suggested a probable connexion between the salting process in cheese-making and the appearance of tallowiness

The degree of oxidation of iron in cheese was also studied Practically no ferrous iron could be extracted from young cheese , but the amount extractable increased with ageing at variable rates, some cheese yielding very little at maturity Cheese tending to tallowiness had increased ferrous iron content, while the actual tallowy seams had the highest ferrous content This occurred in seams where oxidation was most advanced, as shown by high peroxide values and also by oxidation of the sulphydryl groups of the protein These results now indicate that an important part is played by an iron complex The very low copper content at the centre of tallowy seams may be an effect of oxidation of a copper–sulphydryl compound similar to that demonstrated by Stricks and Kolthoff[1]

Most of these investigations were carried out during a period of several years In view of the recent finding by Rammell (following communication) that hæmatin compounds can cause tallowy discoloration, they support the view that these or similar iron complexes have an important influence in causing tallowy discoloration.

Fat Oxidation and Hæmatin Systems in Cheese

MUCH work has been done in New Zealand on a defect of Cheddar cheese characterized by a coupled oxidation of the fat and carotene. The defect, commonly known as 'tallowy discoloration' or 'white streak', is seen in the interior of the cheese as bleached areas having a tallowy flavour. These bleached areas are invariably associated with cracks in the body of the cheese. The defect usually occurs only after at least 16–20 weeks storage at low temperatures (42–44° F.). Previous attempts to find the major pre-disposing cause of this defect have not been completely successful.

As I believe the defect to be similar in several ways to oxidative changes described by Tappel[1], attempts were made to show the presence of a fat-oxidizing system in cheese, using methods similar to those of Blain and Todd[2]. Such a system was found to be present in some cheese. As a result of these findings, cheese was made in which sterile, defibrinated cow's blood was added to the cheese milk. The experimental and control cheese were stored in a controlled curing room at about 55° F. for 6 weeks. Sample plugs of the cheese were then stored in the presence of air, at 32–34° F. for 4 weeks. After this time, the cheese containing the highest amount of blood (0.02 per cent in the cheese milk) had developed typical tallowy discoloration. The control cheese containing no added blood had not developed the defect; it was of normal flavour and colour.

On obtaining these results, four of the original experimental and control cheeses were cut and examined. These cheeses had been at 55° F. for 2 weeks followed by 9½ weeks at 42–44° F.—a total of 11½ weeks. Tallowy discoloration was seen in the two experimental cheeses, being more extensive in the cheese containing the higher amount of blood. The two control cheeses showed no sign of the defect.

The possibility of abnormal amounts of blood in the milk being the prime cause of tallowy discoloration must now be considered. It has been shown that, during manufacture of experimental cheese, most of any red blood cells added to the milk become concentrated within the cheese curd. This concentration is further modified by the addition of salt to the curd, resulting in a partial hæmolysis of the red blood cells. Higher concentrations of salt would then be expected to reduce tallowy discoloration. The effect of added salt provides a possible partial explanation of the results obtained by Bishop (preceding communication).

Full details of these and related experiments will be offered for publication elsewhere.

C. G. RAMMELL

NON-INVERTED VERSUS INVERTED PLOTS IN ENZYME KINETICS

IT was first shown, but not published, by Woolf (see ref. 1) that the Michaelis–Menten equation $v = V_m/(1 + K_M/S)$, relating the initial reaction-rate (v) of an enzymic reaction to the substrate concentration (S) can be written in three linear forms. The experimental (apparent) kinetic constants V_m (v, when $S \to \infty$) and K_M (S, when $v = V_m/2$) can be obtained from plots of the variables $1/v$ versus $1/S$, S/v versus S or v versus v/S. Since its first application by Lineweaver and Burk[2], the $1/v$ versus $1/S$ plot has been used most commonly.

However, it has been pointed out on several occasions (see ref. 3), that the v versus v/S plot, non-inverted with respect to v, has advantages over the two inverted plots, partly because it is less apt to obscure deviations from linearity. With respect to similar plots for determining the number of molecules of a small molecular compound bound to a protein, Scatchard[4] states ". . . this [inverted plot] has the disadvantage of concealing deviations from the ideal laws and of tempting straight lines where there should be curvature".

These considerations apply also to the determination of kinetic constants from enzymic reaction-rates at constant substrate concentration and varying concentrations of an inhibitor or activator (see ref. 5).

Despite the drawbacks it has remained customary, at least in enzyme kinetics, to use inverted plots in the evaluation of results. Even in a recent and authoritative text-book on enzymology[6] that treats these graphical procedures extensively, the advantages of the v versus v/S plot have not been fully recognized. For these reasons some further comment on this matter seems to be appropriate.

In an acid-base titration, or in the demonstration of the influence of the hydrogen ion concentration on the rate of an enzymic reaction, unwieldy graphs would be obtained if instead of pH the hydrogen ion concentration were used as one of the co-ordinates. This applies also to the influence of the substrate concentration on the rate of an enzymic reaction, and accordingly plots of v versus pS have been used in enzyme kinetics. The inflexion point of the theoretical sigmoid curve corresponds to pK_M.

Like other titrations, the enzyme–substrate 'titration' should be carried out over a range that includes substrate concentrations above as well as below this inflexion ('halfway') point. An ideal range is that of about one pS unit below to one pS unit above this point, that is, from about 0.1 to 10 K_M[5,7], representing roughly the range of 10–90 per cent 'saturation' of enzyme with substrate. However, such a (semi) logarithmic plot is still of little value for the estimation of the kinetic constants because it is not linear. On this basis, the advantage of the v versus v/S plot becomes immediately apparent. It can be seen in Fig. 1 that for almost 80 per cent of its course this plot nearly coincides with the v versus pS plot. It has the additional advantage over the latter of being linear, which allows V_m to be determined by extrapolation to $S \to \infty$ (intercept with the ordinate). The (negative) slope is equal to K_M.

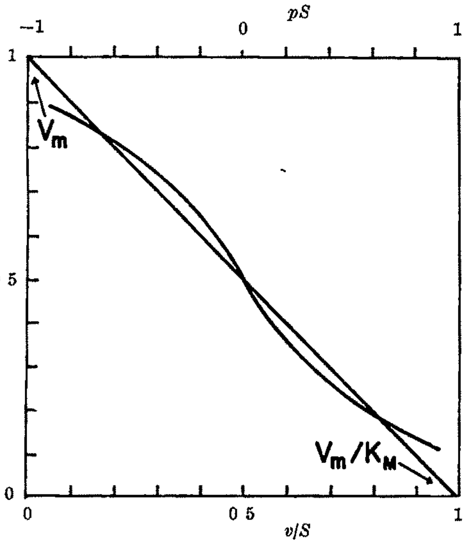

Fig 1. Comparison of the v versus pS (sigmoid) and the v versus v/S plot (straight line). V_m has been taken as unity for the reaction-rate (v) and K_M as unity for the substrate concentration (S)

If, in the ideal region, substrate concentrations are applied that correspond to about equal increments in pS, a procedure that has been found practicable in many cases (for examples see ref. 8), the reaction-rates actually measured also change by about equal increments and are equally distributed over the v versus v/S plot. This is not the case with the other two plots when equal increments of $1/S$ or S are taken. In this connexion a few comments on statements made by Dixon and Webb (ref. 6, pp. 21–22) are in order. These statements are: "... the experimenter is free to choose such substrate concentrations as will give the best distribution of points (one very rarely works at equal increments of v, indeed it is hardly practicable to do so)" and "... it is a positive advantage to have most of the points concentrated near the left hand side in [the two inverted] methods, since it is this part of the graph which is most important for determining K_M". When, in the inverted plots, the substrate concentrations are chosen so as to give equal distribution of points, one finds that the corresponding changes in rate decrease progressively at one end of the curve until they become too small to be measured accurately. On the other end of the curve, the increments in v become unnecessarily large. This is demonstrated by Figs. 2A and 2B for the case of the $1/v$ versus $1/S$ plot. Fig. 2 is based on a substrate concentration-range of about 10-fold, but one frequently finds in the literature cases where the range is even smaller so that, for example, only the lower points of curve 2B are available. Although a more or less accurate V_m/K_M value (intercept with the abscissa in the non-inverted plot) may be obtained in this case, it is obvious that neither V_m nor K_M can be estimated with any accuracy from such data, even though the inverted plot might tempt one to do so. Similar difficulties obtain when only results at the higher substrate concentrations, close to saturation, are available. From such data not even V_m can be estimated with certainty when substrate inhibition is involved.

Because only the v versus v/S plot shows the rates from $S \to 0$ to $S \to \infty$ on a finite graph, this plot generally demonstrates more clearly whether or not the results are sufficient for the estimation of the constants. When ample data are available, for example, over the recommended 100-fold range of substrate concentrations, the inverted plots are also the less convenient. As is seen in Fig. 2A, all the activities below $V_m/2$ would be found on the first small part of the curve between $1/S = 0$ and $1/S = 1$, while those above this value correspond to the range of $1/S$ between 1 and infinity. Thus, the inverted plots over-emphasize the results on one side of the curve at the cost of those on the other side. This produces a lop-sided stretching of the curve and tends to obscure deviations from linearity (see ref. 3b).

No titration is complete, nor the estimation of the corresponding constants accurate, if it is not carried through on both sides of the half-way point. Both these regions are of equal value in this respect. On the other hand, results obtained too far away from this point on either side are largely superfluous. From this it should be clear that the most important range of substrate concentrations for the determination of the constants are those of the order of K_M, around the value of which the curve should be symmetrical. This is the case only with the v versus v/S plot in which the half-way point is equally spaced between the two limiting values

$$V_m\left(=\lim_{S\to\infty} v\right) \quad \text{and} \quad V_m/K_M\left(=\lim_{S\to 0} v/S\right)$$

Another largely unwarranted comment that has been made from time to time (see ref. 9) in favour of the $1/v$ versus $1/S$ plot is based on the fact that here the variables v and S are separated. With respect to estimation of the experimental error and the weighting of data, this does not constitute an argument against the v versus v/S plot when only the error in v needs to be considered, as is most often the case. In the v versus v/S plot an error in v simply displaces the experimental point along a line through the origin that

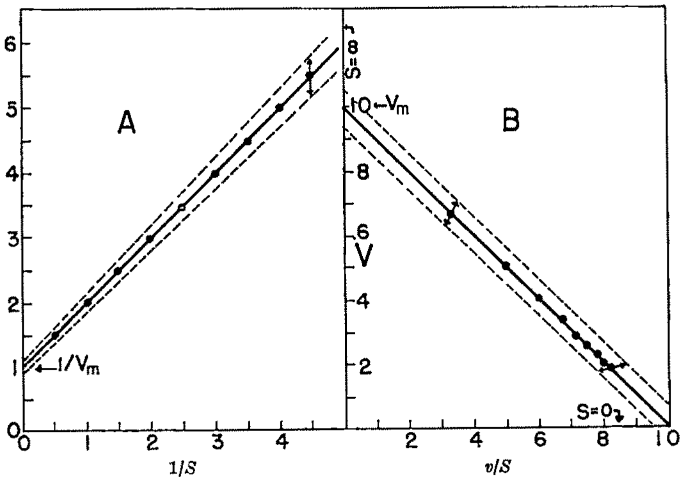

Fig 2. Comparison of the same (hypothetical) data in a $1/v$ versus $1/S$ plot (A) and a v versus v/S plot (B), showing that (1) points that are equally distributed in the inverted plot correspond to an unfavourable distribution of rates actually measured, and (2) a limited set of results that do not allow extrapolation, that is, the points on the lower part of curve B are over-emphasized in the inverted plot (A). The arrows and the zones within the dotted lines correspond to an experimental maximum error in v of ± 5 per cent

represents a particular substrate concentration The displacements are indicated by the arrows in Fig 2*A* and 2*B*, where the dotted lines show the zone in which the experimental points are found when subject to a maximum error of ±5 per cent It may be noted that in the v versus v/S plot this zone runs parallel to the theoretical curve in contrast to the inverted plot

In view of the reasons discussed above, it would seem then that there is no real basis for the continued use of the inverted plots

THERE seems to be some confusion here between two things which are in reality quite distinct, namely, (*a*) the choice of the series of substrate concentrations which will give the best results, and (*b*) the best method of plotting the results obtained These are largely independent one is free to select the best series of concentrations without even knowing which method of plotting will be used, and when the results have been obtained one is free to plot them by either method

With regard to the choice of substrate concentrations, we have in fact made no recommendation that the series should give equally spaced points on the reciprocal plot (namely, "equal increments of $1/S$"), as Dr Hofstee seems to imply, nor do we recall any such recommendation by others On the contrary, our statement that it is advantageous to have a concentration of points near the left-hand side of this plot implies approval of some such series as "equal increments of pS"

With regard to the method of plotting, both methods are of course perfectly valid, and it is our belief, based on experience of plotting results in both ways, that there is not a great deal to choose between them This is where we differ from Dr Hofstee, who believes that plot *B* (Fig 2) is so greatly superior to plot *A* that there is no reason for the continued use of the latter

The purpose of plotting is twofold (*a*) to determine K_M and V_m, and (*b*) to check that the system obeys the Michaelis equation ('linearity', that is, of the graphs) By actual use, we find that the two methods are about equally good in both respects, the accuracy of determination of the constants from a given set of results is about the same, and it seems to us that deviations from linearity are revealed almost equally well by the two methods We venture to think that if the reader will plot a few cases in both ways he will come to the same conclusion

A main argument for plot *B* seems to be that a series of concentrations of the kind commonly preferred will give a more uniform distribution of points along the straight line than in the case of plot *A* It does not follow, however, that such a uniform distribution of points will give the most accurate results, for we would point out that the position of a straight line is determined much more precisely by points near its ends than by points near its centre

Our main reason for preferring plot *A* is that one can readily identify the different points with particular substrate concentrations, and so see what is taking place This is not the case with plot *B*, which has no scale of substrate concentrations, the quantity which is plotted depends both on the arbitrarily fixed concentration and the resulting observed velocity, so that it is necessary to perform a division sum to discover what substrate concentration corresponds to a given point Any error in v affects both co-ordinates, displacing the point obliquely Also rather more calculation is involved in the actual plotting by this method We think that many workers will continue to use plot *A*, the inverted, or as we would prefer to call it, the reciprocal plot

TWO-DIMENSIONAL HIGH-VOLTAGE PAPER ELECTROPHORESIS OF AMINO- AND OTHER ORGANIC ACIDS

By DR. D GROSS
Tate and Lyle, Ltd, Research Laboratory, Keston, Kent

Amino-Acids

IT had been demonstrated before[1] that the application of high potential gradients to the electrophoresis of amino-acids leads to sharp separations after comparatively short running times It was felt, however, that a higher degree of resolution and greater certainty of identification of the separated compounds could be attained by the adoption of a two-dimensional technique, that is, subjecting the sample to electrophoresis on the same sheet under two different pH conditions with consequently differing migration patterns

A two-dimensional technique for the separation of amino-acids has been described by E L Durrum[2], who obtained encouraging results with mixtures of

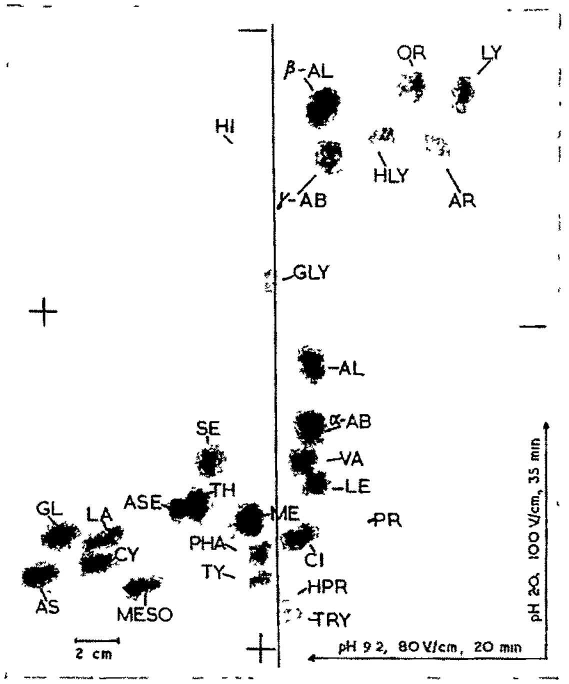

Fig 1 Two-dimensional high-voltage electrogram of amino-acids Conditions first direction (bottom to top), Whatman No 3 *MM*, 12 in × 22½ in 0 75 *M* formic acid, *p*H 2 0, 100 V /cm , 6 5 m amp /cm , cooling water temperature 16° C , pressure 1 5 lb /in ^{2}, 35 min , acidified ninhydrin reagent (0 5 per cent w/v) in acetone, 10 µgm of each amino-acid , second direction (right to left), 0 05 *M* sodium borate solution, *p*H 9 2, 80 V /cm , 9 m amp /cm , 20 min

Amino-acids *α-AB*, α-amino-butyric acid , *β-AB*, β-amino-butyric acid , *γ-AB*, γ-amino-butyric acid , *AL*, α-alanine , *β-AL*, β-alanine , *AR*, arginine , *AS*, aspartic acid , *ASE*, asparagine , *CI*, citrulline , *CY*, cystine , *GL*, glutamic acid , *GLY*, glycine , *HI*, histidine , *HLY*, hydroxylysine , *HPR*, hydroxy-proline , *LA*, lanthionine , *LE*, leucine , *LY*, lysine , *ME*, methionine , *MESO*, methionine sulphone , *OR*, ornithine , *PHA*, phenyl-alanine , *PR*, proline , *SE*, serine , *TH*, threonine , *TRY*, tryptophan , *TY*, tyrosine , *VA*, valine

up to 13 amino-acids, a potential gradient of 30 V /cm and a running time of 5 hr Several authors[3] have since reported modifications to this technique employing relatively low voltages, but without an apparent significant increase in resolving power, expediency or speed of operation A recently constructed apparatus of sufficient width and improved cooling efficiency made the application of high potential gradients (100 V /cm and greater) to two-dimensional separations of amino-acids possible[4], and the technique has since been improved and usefully employed in several investigations

The procedure found most practical is as follows a sheet of filter paper, Whatman No 3 *MM*, 12 in × 22½ in, is soaked in a 0 75 *M* formic acid solution of *p*H 2 0 and blotted to remove excess moisture The sample is applied as a streak of ½ in width, the sheet placed in the electrophoretic apparatus (sandwich type, top and bottom cooling plates, 13 in × 20 in, strictly controlled pressure) and connected through a 'Cellophane' membrane[5] at each end with the thick paper pads dipping into the electrolyte vessels It is run for up to 40 min , dried for 10 min at 90° C and 1 hr in a stream of cold air to remove most of the formic acid residue, trimmed to a length of 12 in , according to a developed guide-strip showing the effective length of separation, and sprayed lightly (approx 135 per cent moisture) from an atomizer with a 0 05 *M* sodium borate solution of *p*H 9 2 It is then turned through 90°, placed carefully in the apparatus, connected by two 12 in × 6 in paper strips to the thick paper pads and thus to the electrode vessels, the joins being made by filling in the small gaps between sheet and strips with a slurry of cellulose powder (Whatman, standard grade) in borate solution Simple overlapping interferes with efficient cooling and steadiness of moisture-level in the sheet After completion of the second run, at 100 V /cm for 20 min , the sheet is detached from the connecting strips, dried for about 15 min at 70° C and sprayed with a 0 5 per cent (w/v) ninhydrin solution in acetone, acidified by the addition of 3 per cent (v/v) of glacial acetic acid It is advisable to place the sheet for spraying with borate solution on a frame provided with a grid of nylon thread and to handle moist electrograms with rubber gloves throughout, to avoid interfering finger marks

Fig 1 shows the pattern of 27 amino-acids and amides separated by this technique

The position of glutamine coincides with that of methionine and, if the presence of both is suspected, it was found practicable to treat the applied sample with two drops of 30 per cent hydrogen peroxide before the first run, to convert the methionine to methionine sulphone[6] which is well separated from glutamine The treatment only works in an acid medium Taurine and cysteic acid can easily be separated from all the other amino-acids at *p*H 2 0 and their identification requires no confirmation by a run at a different *p*H In this case, they would be below tryptophan, separated by a wide gap from it and from one another The position of tryptophan at *p*H 2 0 was always found as shown and not, as J K Whitehead reported[3], near glycine

Fig 2 demonstrates the application of the technique to a commercial sample of acid-hydrolysed casein

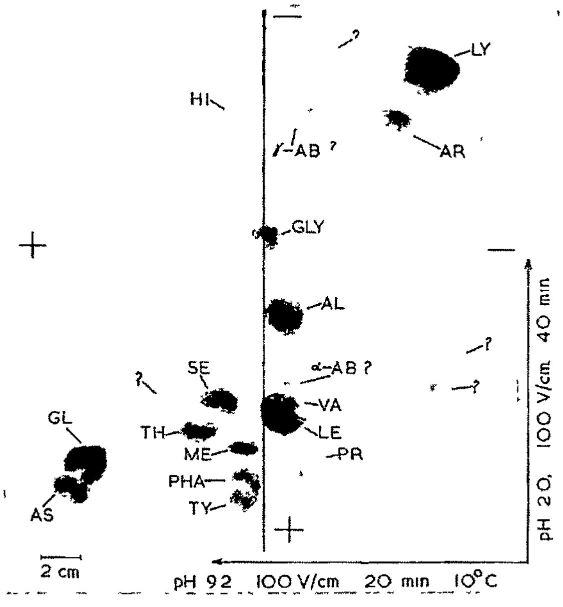

Fig 2 Two-dimensional high-voltage electrogram of a casein hydrolysate

Conditions first direction (bottom to top), Whatman No 3 *MM*, 12 in × 22½ in , 0 75 *M* formic acid, *p*H 2 0, 100 V /cm , 6 m amp /cm , cooling water temperature 10° C , pressure 1 5 lb /in ^{2}, 40 min , ninhydrin reagent as in Fig 1, 250 µgm of hydrolysate , second direction (right to left), 0 05 *M* sodium borate solution, *p*H 9 2, 100 V /cm , 9 5 m amp /cm , 20 min

Amino-acids as in Fig 1

Most of the common amino-acids can be identified by their positions, the appearance of some spots in unusual positions may be due to the presence of peptides or other ninhydrin-reactive compounds No attempt has been made to identify the compounds against which question marks are placed The partial overlapping of valine and leucine (or the leucines) is due to their relatively high concentrations The slight difference in migration distances in the second direction is due to a lower temperature and moisture content of the sheet Under standardized conditions the degree of reproducibility of the spot patterns is usually high The time for the separation of less complex mixtures can be reduced in many cases to about one half

Other Organic Acids

As a result of a systematic study of the migration-rates of non-volatile organic acids under varying conditions of pH, ionic strength and composition of background electrolyte[7], it was found possible to improve greatly the resolution of complex mixtures by choosing three well-tested buffer or electrolyte solutions of pH 2 0, 4 0 and 8 9 with advantageous differences in rate and sequence of migration

With the availability of an improved electrophoretic apparatus of sufficiently large dimensions[4], the feasibility of a two-dimensional technique became apparent and was successfully tried The two-dimensional technique, as in paper chromatography, allows the best use of the resolving power inherent in the electrolyte systems chosen, particularly in conjunction with the application of a high-voltage technique ensuring clean separations with a minimum of diffusion and liquid flow effects This high degree of resolution is particularly desirable when dealing with a multitude of organic acids as potentially present in complex biological and plant extracts The previously described[8] 0 75 M formic acid solution, found most suitable for the separation of strong and moderately strong acids from weak acids, has the disadvantage of largely suppressing the ionization of the weak acids, with attendant loss of mobility

At higher pH values the degree of ionization increases appreciably and with it the mobilities of the weak acids, which makes separation and identification of the individual acids based on their varying migration-rates feasible Two electrolyte solutions, namely, a 0 5 M acetic acid solution adjusted with pyridine to pH 4 0, and an approximately 0 1 M ammonium carbonate solution of pH 8 9, were found to offer suitable variations in migration-rates without the formation of multiple spots resulting from partial dissociation Ammonium carbonate solution had proved its usefulness in the electrophoresis of inorganic acids, volatile fatty acids[9] and some non-volatile organic acids[10]

The procedure adopted followed closely that developed for the two-dimensional separation of amino-acids The first run was at pH 8 9 and the second run at pH 4 0 or 2 0 The sheet was soaked in the electrolyte and blotted before streaking the sample over a width of 2 5 cm, run and dried for 15 min at 90° C Before the second run, the electrolyte was lightly sprayed from an atomizer on both sides of the paper sheet to a sufficient degree of moistness (about 135 per cent on dry paper) to ensure electrical conductance without displacing the partially separated acids

Runs of 25-min duration in each direction were found appropriate under the electrical conditions chosen, though with less complex mixtures the time can be reduced to 15 min for each run The sheet was dried after the second run for 10 min at 85° C and kept for 1 hr in a stream of cold air to remove the residual acetic acid (formic acid required at least 3 hr) before being sprayed with a suitable reagent The choice of a useful reagent for organic acids is restricted to indicator solutions of relatively high sensitivity (provided the background has been cleared of residual traces of free acids or bases) and low stability of colours and chemical reagents producing a colour due to the presence and pH of the acid on the paper and subsequent heating The strength of such a reaction varies with the type of acid present, and its sensitivity is usually lower than that of an indicator reagent, but the stability of the colours is much higher and the presence of traces of residual electrolyte is not so critical

Of the many reagents tried, the aniline–glucose reagent with heating at 115° C was found to give satisfactory results for most acids, and the ferric chloride – potassium ferricyanide reagent[11] without heating proved useful for syringic, lactic, glycollic and tartaric acid

A 0 025 per cent solution of bromocresol purple in ethanol–water (75 25) provided a useful and sensitive indicator reagent which could also be applied prior to spraying with the aniline–glucose reagent, the latter providing a permanent record of brown spots on a near-white background Picric acid, a coloured compound, was used as a marker to indicate the progress of migration

An example of a separation of twenty organic acids is illustrated by the electrogram in Fig 3

Thanks are due to Mr R W Butters for valuable technical assistance, Mr D G Harrison for skilful

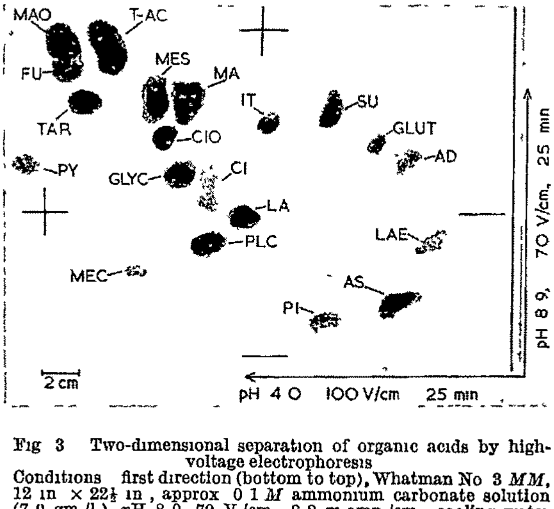

Fig 3 Two-dimensional separation of organic acids by high-voltage electrophoresis

Conditions first direction (bottom to top), Whatman No 3 *MM*, 12 in × 22½ in, approx 0 1 M ammonium carbonate solution (7 9 gm /l), pH 8 9, 70 V /cm, 8 2 m amp /cm, cooling water temperature 12° C, 1 5 lb /in ^{2}, 25 min, second direction (right to left), 0 5 M acetic acid adjusted with pyridine to pH 4 0, 100 V /cm, 10 m amp /cm, 25 min, 50 μgm of each acid Spraying reagent glucose-aniline (approx 2 per cent of each) in ethanol–water (2 8)

ACTION OF MANGANESE DIOXIDE ON SIMPLE CARBOHYDRATES

By Dr. J. L. BOSE, Dr. A. B. FOSTER, Prof. M. STACEY, F.R.S., and Dr. J. M. WEBBER

Chemistry Department, The University, Birmingham, 15

UNDER mild conditions, manganese dioxide (MnO_2) selectively oxidizes αβ-unsaturated alcohols to the corresponding carbonyl compounds[1], N-alkyl and N,N-dialkylanilines are also attacked, yielding amides[2]. Elevation of the temperature (70–120°) results in a reduced selectivity of oxidizing action and a variety of reactions have been observed[1,3], some of which were carried out in aqueous media. We now report a preliminary qualitative survey of the action of manganese dioxide on simple carbohydrates.

Initially the activity of manganese dioxide preparations obtained by the following methods were compared: (1) alkali-permanganate[4], (2) acid-permanganate[5], (3) decomposition[6] of manganese oxalate at 250°, (4) decomposition[6] of manganese carbonate at 250°, (5) preparations (1)–(4) after nitric acid treatment[6]. The alkali-permanganate product gave an aqueous extract *p*H *c.* 10 even after multiple treatments with water, but the remainder gave neutral extracts. Three reaction conditions were employed in which a solution of the carbohydrate (50 mgm.) in water (1·5 ml.) was vigorously shaken with manganese dioxide (*A*) 50 mgm. at 50° for 1 hr., (*B*) 50 mgm. at 95–100° for 1 hr., (*C*) 150 mgm. at 95–100° for 1 hr. These ratios of oxidant to substrate are considerably lower than those often used with other types of compound[1]. The filtered solutions were examined by (1) paper chromatography (downward irrigation with the organic phase of a butanol/ethanol/water (4:1:5) solvent system), (2) paper ionophoresis (enclosed strip technique[7]) with a borate buffer[8] *p*H 10 and an acetate buffer *p*H 5 and detection with aniline hydrogen phthalate[9] and alkaline silver nitrate[10]. Identification of products must be considered tentative, although the application of chromatography and ionophoresis in conjunction permits a more certain identification[11]. The chain-length of each acid formed in the oxidations was determined by ionophoresis in acetate buffer, and mobilities expressed as M_{GA} values (GA = gluconic acid) give the sequence: gluconic acid 1·00, arabonic acid 1·09, erythronic acid 1·27, glyceric acid 1·54 and glycollic acid 1·77.

Slight differences were observed in the effect of the various manganese dioxide preparations on glucose and fructose. The subsequent results were obtained with manganese dioxide prepared from the carbonate since it is the easiest and cheapest to prepare.

Aldoses and related compounds. From Table 1 it may be seen that the hexoses yielded pentoses together with acidic products. The hexose → pentose conversion is not a normal oxidation pathway of sugars, although it can be effected by glycol cleavage reagents[12], and amino-sugars may be degraded to pentoses by ninhydrin[13]. Both hexose and pentose were obtained *inter alia* from the heptose. The susceptibility of erythrose to oxidation was quite striking; it reacted completely under conditions *B* and *C* and hence did not appear as an oxidation product of the higher sugars other than of pentoses under condition *A*.

When galactose was treated under condition *A* with manganese dioxide, obtained from the alkali-permanganate reaction, in addition to the products shown in Table 1 traces of erythrose could also be detected, and under condition *B* epimerization occurred yielding talose and tagatose. This observation is not surprising in view of the alkalinity of the reaction solution.

Table 1. OXIDATION OF ALDOSES AND DERIVATIVES WITH MANGANESE DIOXIDE

Aldose	Reaction condition	Products*
Galactose†	*A*	Galactose, trace lyxose
	B	Galactose, lyxose, traces of 5C and 4C acids
	C	Galactose, lyxose 6C, 5C, 4C and 3C acids
D-*Glycero*-D-*galacto*-heptose	*A*	Heptose, trace mannose
	B, *C*	Heptose, mannose, traces of arabinose and 6C acid
Ribose‡	*A*	Ribose, trace erythrose, 4C acid
	B, *C*	Ribose, arabinose, 5C, 4C and 3C acids
Erythrose	*A*	Erythrose, 3C acid
	B, *C*	4C, 3C and traces of other acids (erythrose completely oxidized)
2-Deoxy-D-'galactose' 2-Acetamido-2-deoxy-D-glucose	*A*, *B*, *C*	Traces of unidentified products
3-O-methyl glucose	*A*	3-O-methyl-glucose, trace 2-O-methyl-arabinose, 6C acid
	B, *C*	3-O-methyl-glucose, 2-O-methyl-arabinose, 6C acid
Rhamnose	*A*	Rhamnose, 5-deoxy-arabinose, 5C acid
	B, *C*	Rhamnose, 5-deoxy-arabinose, 5C, 4C, 3C acids
2-Amino-2-deoxy-D-glucose hydrochloride	*A*, *B*, *C*	Complex mixture of products

* Traces of unidentified compounds were detected in several cases and manganese ions were invariably present. This comment is also applicable to the results in Tables 2 and 3.

† Parallel results with glucose, mannose and other hexoses.

‡ Parallel results with xylose and arabinose.

Table 2 ACTION OF MANGANESE DIOXIDE ON SOME REDUCING DISACCHARIDES

Disaccharide	Linkage	Reaction condition	Products*
Sophorose	β 1 → 2	*A*, *B*, *C*	Insignificant reaction
Laminaribiose (M_G 0 66)	β 1 → 3	*A*	Laminaribiose, trace *G-A* (M_G 0 33), trace acid P (M_{GA} 0 73)
		B, *C*	Laminaribiose, *G-A*, P, glucose, arabinose
Maltose (M_G 0 30)	α 1 → 4	*A*	Maltose, trace *G-A* (M_G 0 56), trace *G-T* (M_{GA} 0 76)
		B, *C*	Maltose, *G-A*, *G-T*, glucose
Cellobiose (M_G 0 26)	β 1 → 4	*A*	Cellobiose, trace *G-A* (M_G 0 57), trace *G-T* (M_{GA} 0 77)
		B, *C*	Cellobiose, *G-A*, *G-T*, glucose, arabinose, *Q* (M_G 0 30)
Melibiose (M_G 0 74)	α 1 → 6	*A*	Melibiose, trace *Gal-A* (M_G 0 87), trace *R* (M_G 0 42)
		B, *C*	*Gal-A*, *R*, trace acid *S* (M_{GA} 0 94), trace galactose and lyxose

* *G–A* indicates glucosyl–arabinose *G–T* indicates glucosyl-tetronic acid *Gal-A* indicates galactosyl-arabinose M_G value is the ionophoretic mobility in borate buffer with respect to that of glucose (ref 11), R_G value is the paper chromatographic mobility with respect to that of glucose

Enhanced resistance to oxidation is conferred by the absence of a C_2-hydroxyl group (2-deoxy-D-'galactose') and substitution at C_2 (2-acetamido-2-deoxy-D-glucose) The results with 3-O-methyl-D-glucose and rhamnose indicate that manganese dioxide oxidations might have some value for the synthesis of, for example, O-methyl- and deoxy-pentoses Although a chromatographic separation of the product would be necessary, application of this technique is also frequently essential in the more classical synthetic methods

Reducing disaccharides In examining the behaviour of disaccharides with manganese dioxide the analytical methods noted above were supplemented as follows The acidic products were separated from the neutral components by absorption[14] on 'Deacidite *FF* 530' (CO_3'' form) followed by elution with ammonium carbonate The neutral and acidic products were then hydrolysed separately with 2*N*-hydrochloric acid at 95–100° for 3 hr, and after neutralization with methyl di-*n*-octylamine[15], the hydrolysates were examined by chromatography and ionophoresis

From Table 2 it is seen that the disaccharides yielded less complex mixtures on oxidation than did the aldoses The 1 → 2 linked disaccharide (sophorose) was largely unaffected by manganese dioxide, whereas the 1 → 3, 1 → 4 and 1 → 6 linked disaccharides were each degraded to give mainly a glucosyl–pentose together with a small amount of apparently a glycosyl–glyconic acid Small amounts of hexose and pentose were also formed, but no 6-carbon or smaller acids As might be expected from the aldose oxidations, glucosyl–tetroses did not accumulate on oxidation of the 1 → 4 and 1 → 6 linked disaccharides The use of a large excess of oxidant did not completely convert maltose into its oxidation products These results suggest that manganese dioxide oxidation might provide a convenient method for converting suitable hexosyl hexoses into hexosyl-pentoses (Glycol cleavage reagents might also be used for this purpose[12]) Although a column chromatographic separation would be necessary to isolate the required product, it should be noted that, with the 1 → 3 and 1 → 4 linked glucosyl–glucose oxidation mixtures, the markedly different M_G values of the glucosyl–glucose and the glucosyl–pentose create an ideal situation for the application of borate–charcoal–'Celite' chromatography[16] Further, the sensitivity of the 1 → 3 linked disaccharide (laminaribiose) towards lime-water permits[17] complete destruction of unoxidized disaccharide, leaving the 1 → 2 linked glucosyl–pentose unaffected

Ketoses and miscellaneous compounds From Table 3 it is seen that fructose variously yielded tetrose or underwent epimerization in addition to the formation of acids Inosose, sodium gluconate and glucurone were readily oxidized, but most of the products of these reactions have not been identified and they are being actively investigated The conversion of hexitols to hexoses and pentoses is of interest The symmetrical hexitols (galactitol and mannitol) gave a single hexose and pentose, whereas glucitol gave two hexoses and two pentoses, indicating attack at both ends of the carbon chain

It is clear that a wide range of carbohydrates is attacked by manganese dioxide and that a variety of oxidation pathways is operative Some of the reactions may be of potential value for the preparation of otherwise inaccessible carbohydrates

A number of commercially available oxides were also examined for action on galactose and fructose under condition *A*

Zinc oxide (ZnO), cadmium oxide (CdO), nickel oxide (Ni_2O_3) and black and grey cobalt oxide (Co_2O_3—Co_3O_4) caused slight epimerization

Zirconium dioxide (ZrO_2) and lead oxides (PbO_2, PbO and Pb_3O_4) showed weak manganese dioxide-type properties (namely, galactose → lyxose), but PbO and Pb_3O_4 effected slight epimerization There was negligible effect on fructose Under condition *B* almost complete destructive oxidation of the substrates occurred with the lead oxides

The following oxides displayed no oxidative action HgO (red and yellow), Hg_2O, UO_3, Cu_2O, CuO, Bi_2O_3, SnO, SnO_2, MoO_3, Nb_2O_5, Y_2O_3, Sb_2O_3, Fe_2O_3, Fe_3O_4, GeO_2, V_2O_5, Cr_2O_3, TiO_2

Table 3 OXIDATION OF CARBONYL-CONTAINING AND OTHER CARBOHYDRATES

Compound	Oxidation condition	Products
Fructose*	*A*	Fructose, tetrose, 5C acid
	B, *C*	Fructose, glucose, mannose, 6C, 5C, 4C and 3C acids
Inosose	*A*, *B*, *C*	Inosose, mixture of acids and reducing acids
Sodium glucuronate†	*A*	No significant effect
	B, *C*	Glucuronic acid, trace of 4C, 3C acids, dicarboxylic acid and other unidentified components
Sodium gluconate‡	*A*	Gluconic acid, reducing acid, trace arabinose
	B, *C*	Gluconic acid, reducing acid, arabinose, unidentified components
Potassium glucarate	*A*, *B*, *C*	Glucaric acid, traces of reducing and acidic products
Galactitol§	*A*	Galactitol, trace galactose
	B, *C*	Galactitol, galactose, lyxose
Glucitol	*A*	Glucitol, trace glucose and gulose
	B, *C*	Glucitol, glucose, gulose, xylose and arabinose
Methyl α-D-glucopyranoside	*A*, *B*, *C*	Traces of unidentified products
Sucrose	*A*	Sucrose, trace of reducing component *S* (M_G 0 41)
	B, *C*	Sucrose, *S*, glucose, fructose and acid T (M_{GA} 0 73)

Parallel results with (*) sorbose, (†) glucurone, (‡) glucono-δ-lactone, (§) mannitol

CROSS-LINKING OF CELLULOSE ACETATE BY IONIZING RADIATION

By Dr. S. H. PINNER, T. T. GREENWOOD and D. G. LLOYD
Tube Investments Research Laboratories, Hinxton Hall, nr. Cambridge

RECENT studies on the polymerization induced by radiation of allyl esters have revealed that the conversion-rate is markedly increased in the presence of polyvinyl chloride, while at the same time the polyvinyl chloride acquires a high density of cross-linking[1]. Polyvinyl chloride belongs to the class of polymers which undergo cross-linking by radiation[2], so that the presence of the allyl ester serves to enhance the action of the radiation but no alteration of mode is involved. It is known that such alterations can occur; for example, in the presence of oxygen, many polymers which are normally cross-linked by radiation may become degraded[3]. An artificial means of rendering a change in the reverse direction constitutes a worth-while objective, as the benefits of cross-linking could then be extended to a large class of polymers such as poly*iso*butylene and cellulose derivatives, but such means have not hitherto been described.

The enhancement of the density of cross-linking in polyvinyl chloride by the presence of the allyl ester was of such magnitude that it seemed feasible to cross-link by radiation, in this way, those polymers the normal response of which to radiation is degradation. Experiments with poly*iso*butylene and polymethyl methacrylate have given ostensible evidence of cross-linking while with secondary cellulose acetate the results leave no shadow of doubt that heavy cross-linking can be achieved. This polymer, like polyvinyl chloride, is normally plasticized to facilitate processing and advantage could thus be taken of the plasticizing action of the allyl ester.

The most obvious effect of replacement of normal plasticizers in cellulose acetate by a convertible plasticizer such as triallyl citrate was that irradiation caused a pronounced increase in tensile strength. This is shown in Fig. 1, where the tensile strength at room temperature of a composition initially containing 32 per cent triallyl citrate is given as a function of the radiation dose, using 2-MeV electrons from the scanned beam of a Van de Graaff accelerator. As shown in the accompanying curve, normally plasticized cellulose acetate exhibited no change in tensile strength over the dose-range studied, despite the radiation damage which was betrayed by darkening, bubbling and reduction in ultimate elongation.

Elevation of the tensile strength at room temperature provided evidence for the polymerization of the triallyl citrate but not, in itself, of cross-linking of the cellulose acetate. The accepted criteria for cross-linking are non-fusibility, non-solubility and reversible high elasticity. Measurements of fusibility were inappropriate in the present instance because of the high melting point of secondary cellulose acetate (*c.* 300°) (ref. 4). Measurements of rubber-like behaviour were similarly thwarted by the inherent stiffness of cellulose acetate chains, and only solubility and swelling criteria can be employed. As is well known, secondary cellulose acetate can be dissolved rapidly in acetone. By contrast, irradiated solid solutions of secondary cellulose acetate in triallyl citrate were highly resistant to acetone. This is shown in Fig. 2, where for a composition containing 32 per cent triallyl citrate, the gel fraction (24 hr. Soxhlet extraction with acetone) and the swelling index (24 hr. in acetone at room temperature) are given as a function of dose. Even a dose as low as 10 Mrads has sufficed to confer a considerable degree of solvent resistance, matching that of similarly cross-linked polyvinyl chloride[1].

For the purpose of exploring the mechanism whereby cellulose acetate has been rendered insoluble, it was desirable to measure the rate of polymerization induced by radiation of the triallyl citrate. Such measurements in the solid state pose a number of problems. Physical methods are generally superior, and density, spectroscopic and relaxation methods have been used[5]. In the present instance, the rate of conversion of the ester has been followed using a Beckman *DK*2 spectrophotometer. Solutions of triallyl citrate in acetone were used to construct a calibration curve relating the absorbance of the 1·625μ allylic absorption band with the allyl concentration and this curve led, with appropriate corrections, to values for residual allyl concentration

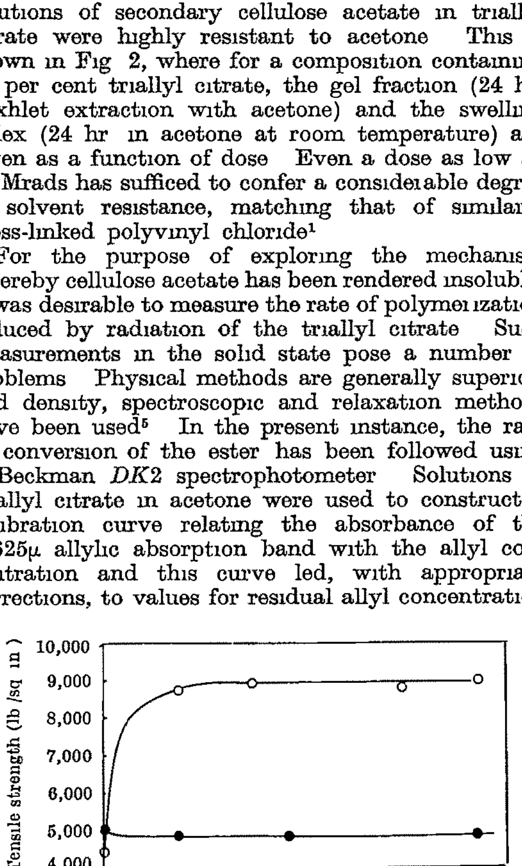

Fig. 1. Tensile strength of irradiated cellulose acetate. ●, Normally plasticized; ○, plasticized with 32 per cent triallyl citrate

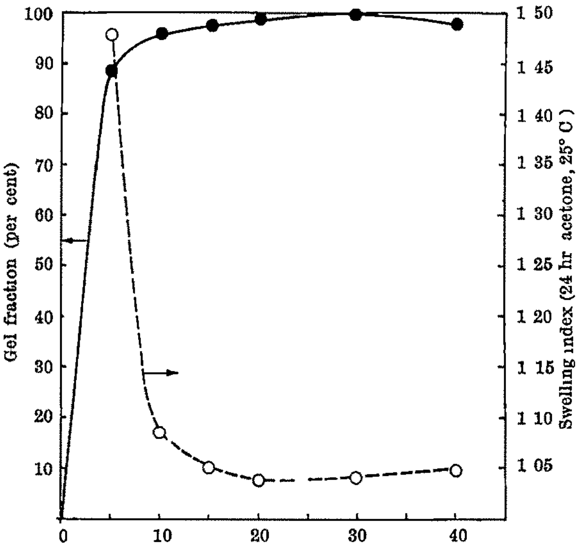

Fig 2 Solubility and swelling of irradiated cellulose acetate ●, Gel fraction (24 hr Soxhlet, acetone), ○, swelling index (24 hr acetone, 25° C)

in irradiated solid solutions of cellulose acetate in triallyl citrate The results are shown in Fig 3, whence, allowing for initial scatter, it is apparent that the disappearance of allyl is essentially proportional to dose up to at least 50 per cent conversion and that the slope is essentially independent of concentration

The average initial allyl disappearance-rate was 0 202 micromole per gram per megarad, corresponding to G (-allyl) = 200 Corresponding figures for the electron-induced homopolymerization-rate are not available, but in view of the relatively small intensity dependence of allyl polymerization, comparison may be made with the rate of homopolymerization induced by γ-rays, which at an intensity of 11,700 rads/min gives G (-allyl) = 103 (Wycherley, V , unpublished work) It follows that while some enhancement of conversion-rate in the presence of cellulose acetate has occurred, the effect is small

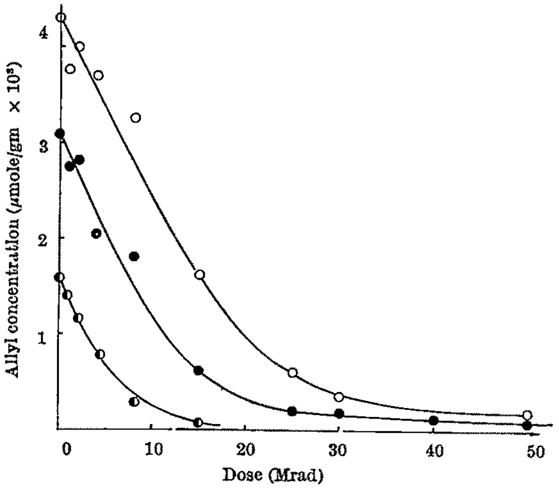

Fig 3 Variation of allyl concentration in cellulose acetate gels Composition containing ○, 45 per cent triallyl citrate, ●, 32 per cent triallyl citrate, ◐, 16 4 per cent triallyl citrate

As an initial hypothesis, it may be considered that the components of the solid solution of cellulose acetate in triallyl citrate respond independently to radiation in their characteristic fashion The hexafunctional monomer when irradiated alone has yielded gel at approximately 10 per cent conversion (Wycherley, V , unpublished work) The rate of radiolysis of cellulose acetate has not been reported, the closest approximation being the fracture-rate for irradiated cellulose, which has been given as G (fracture) = 11 (ref 6) If these processes are superimposed, it follows that the cellulose acetate component will be progressively rendered insoluble by irradiation of the mixture if it becomes attached to the allyl network at a rate exceeding that of radiolysis The mode of attachment is simply that of initiation of an allyl chain, and it remains to consider semi-quantitatively the probable rate of initiation by polymeric cellulose acetate radicals relative to that of scission

The ratio of frequency of chain transfer to frequency of propagation during normal polymerization of allyl esters lies in the range 10–20 (ref 7) Taking the mean for triallyl citrate leads to G (chain initiation) $\simeq 13$ Since the condition for cross-linking is that the probability of forming cross-linking units should be at least half the probability of dislinking, that is, $p_0/q_0 < 2$, the minimum G-value for junction point formation on the cellulose acetate in order for gel to accumulate is 5 5 While it is entirely reasonable that the G value for radical formation produced by radiation in cellulose acetate might equal 5 5, such a rate of initiation could only lead to very slow aggregation of the gel In point of fact, gel aggregation is rapid (see Fig 2), which is more consistent with a value of q_0 exceeding p_0 While G values for initiation by cellulose acetate as high as 10–15 cannot be ruled out, on present limited data, such primary initiation-rates seem abnormally high and it is more likely that a supplementary contribution is made by a process of effective chain-transfer, whereby a growing allyl chain abstracts a hydrogen atom from the cellulose acetate molecule rather than from an allyl monomer molecule, leaving the resultant macroradical to re-initiate a further allyl chain and serve as a junction point with the network In view of the similarity in the triallyl citrate conversion-rate in the presence or absence of cellulose acetate, there is no need, however, to postulate reactivation of resonance-stabilized allylic radicals, as was found necessary in the case of polyvinyl chloride[1]

If this picture is correct, it may be concluded that cross-linked cellulose acetate arises as a consequence of irradiation in the presence of a network-forming monomer, which has a short propagation chain-length and serves as an efficient trap for polymeric radicals whether produced directly by radiation or indirectly by hydrogen abstraction

This work has been carried out in collaboration with B X Plastics, Ltd , and we wish to thank Dr R R Smith and Dr M Pettit for discussion, and the Chairman of B X Plastics, Ltd , and the Chairman of Tube Investments, Ltd , for permission to publish this work

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, November 30

Royal Society (at Burlington House, Piccadilly London, W 1), at 2 30 p m —Anniversary Meeting

Institute of Metal Finishing (in the Canterbury Room of the Charing Cross Hotel, London, W C 2), at 2 45 p m —Mr A A B Harvey "The Role of the Scientific Society" (Presidential Address)

University College (in the Physiology Theatre, Gower Street, London, W C 1), at 5 p m —Prof E P Kennedy (University of Chicago) "The Biosynthesis of Complex Lipids" * (First of two lectures in Biochemistry Further lecture on December 7)

Royal Institution, Library Circle (at 21 Albemarle Street, London, W 1), at 5 30 p m —Dr L Pearce Williams "Faraday Through His Manuscripts"

Royal Geographical Society (at 1 Kensington Gore, London, S W 7), at 8 30 p m —Prof C von Furer-Haimendorf "Sherpas of Eastern Nepal"

Tuesday, December 1

University of London (in the Anatomy Theatre, University College, Gower Street, London, W C 1), at 1 15 p m —Prof R E D Bishop "Vibration Problems in Engineering" *

Institution of Electrical Engineers, Measurement and Electronics Sections (at Savoy Place, London, W C 2), at 5 30 p m —Dr L Essen, Mr J V L Parry and Mr J McA Steele "Frequency Variations of Quartz Oscillators and the Earth's Rotation in Terms of the N P L Cæsium Standard"

University of London (at Imperial College of Science and Technology, London, S W 7), at 5 30 p m —Prof H K Porter "Physiology has No Frontiers" (Inaugural Lecture)

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 5 30 p m —Dr J L Gowans "The Lymphocyte" * (Twelfth of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation Further lectures on December 3, 8, 10)

Plastics Institute (at the Wellcome Building, 183–193 Euston Road, London, N W 1), at 6 30 p m —Mr M R E Ashenden "Plastics and the Law"

Royal Aeronautical Society (at 4 Hamilton Place, London, W 1), at 7 p m —Dr I M Hall "Transonic Flow Over Swept Wings"

Wednesday, December 2

Royal Statistical Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 5 p m —Mr E M L Beale "Confidence Regions in Non-Linear Estimation"

Institute of Petroleum (at 61 New Cavendish Street, London, W 1), at 5 30 p m —Mr J Marechal and Mr P de Radzitsky "Potentialities of Urea in Dewaxing Middle and Heavy Distillates"

Institute of Information Scientists (at the Berners Hotel, 10 Berners Street, London, W 1), at 6 p m —Discussion on "Languages in Information Work—To What Extent is Competence in a Foreign Language an Essential Qualification for an Information Scientist ?"

Wednesday, December 2—Thursday, December 3

Iron and Steel Institute (in the Great Hall, Caxton Hall, Caxton Street, London, S W 1, and the Hoare Memorial Hall, Church House, Great Smith Street, London, S W 1), at 9 30 a m daily—Autumn General Meeting

Thursday, December 3

University of London (in the Anatomy Theatre, University College, Gower Street London, W C 1), at 1 15 p m —Mr P R Bell "The Origin of Indian Corn" *

Royal Society (at Burlington House, Piccadilly, London, W 1), at 4 30 p m —Mr F H C Edgcombe and Prof R G W Norrish, F R S "A Study of the Mechanism of Photochemical Electron Transfer Processes in Solution", Mr I M Dawson and Mr E A C Follett "An Electron Microscope Study of Synthetic Graphite"

Institute of Marine Engineers (joint meeting with the Institute of Naval Architects, in the Weir Hall, 10 Upper Belgrave Street, London, S W 1), at 4 45 p m —Prof G Aertssen "New Sea Trials on the Sandblasted *Lubumbashi*"

University of London (at the London School of Economics and Political Science, Houghton Street, London, W C 2), at 5 p m —Dr E R Leach "Rethinking Anthropology"* (Malinowski Memorial Lecture)

Royal Society of Arts, Commonwealth Section (at John Adam Street, Adelphi, London, W C 2), at 5 15 p m —Mrs Mildred Valley Thornton "Indians of British Columbia"

Institution of Electrical Engineers (at Savoy Place, London, W C 2), at 5 30 p m —Mr C B B Wood and Mr I J Shelley "The Transmission of News Film over the Trans-Atlantic Cable"

Society of Chemical Industry, Microbiology Group (joint meeting with the Society for Applied Bacteriology, at the Royal Society of Medicine, 1 Wimpole Street, London, W 1), at 6 15 p m —Dr F Brown "Infective Ribonucleic Acid from the Virus of Foot-and-Mouth Disease"

Royal Photographic Society, Medical Group (at 16 Princes Gate, London, S W 7), at 7 p m —Sir Stanford Cade, K B E , C B , F R C S "What I Want from a Medical Photograph"

Friday, December 4

Institution of Electrical Engineers, Medical Electronics Discussion Group (at Savoy Place, London, W C 2), at 6 p m —Discussion on 'Nuclear Magnetic Resonance", opened by Dr N. Sheppard and Dr R E Richards

Society of Dyers and Colourists (at the Royal Society, Burlington House, Piccadilly, London, W 1), at 6 p m —Mr R C Oakley : "Dyeing of Ribbons", Mr R Woods "Dyeing of Carpet Yarns"

Royal Institution (at 21 Albemarle Street, London, W 1), at 9 p m —Dr H A Thomas "Electronic 'Brains'"

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Assistant Lecturer in Physics—The Registrar, The University, Manchester 13 (November 30)

Chair of Chemical Engineering—The Registrar, University College, Singleton Park, Swansea (November 30)

Assistant Lecturer in Physiology—The Registrar, The University, Sheffield (December 5)

Lecturer in Physiological Psychology—The Registrar (Room 22, O R B), The University, Reading (December 9)

Lecturer in Social Anthropology, and a Lecturer in Rural Sociology in the Faculty of Economic and Social Sciences—The Registrar, The University, Manchester 13 (December 12)

Organic Chemist, Scientific Officer or Senior Scientific Officer grade in the Department of Hop Research, for research problems related to the hop plant—The Registrar, Wye College, near Ashford, Kent (December 12)

Assistant Lecturer or Lecturer in Applied Mathematics—The Registrar, The University, Sheffield (December 19)

Assistant Lecturer or Lecturer in the Department of Zoology—The Registrar, The University, Liverpool (December 19).

Lecturer/Senior Lecturer (with an interest in, and qualified for teaching and research in any of the main branches of psychology) in Psychology at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (Australia, December 19)

Lecturer in Forest Pathology at the Waite Agricultural Research Institute—The Registrar, University of Adelaide, Adelaide, South Australia (December 21)

Senior Lecturer in Applied Anatomy at the University of Adelaide, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (Australia, December 21)

Senior Lecturer or Lecturer in Psychology at the University of Khartoum—The Registrar, University of Khartoum, c/o Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (December 22)

Senior Principal Scientific Officer (honours graduate in science with appropriate research experience) with the Hill Farming Research Organization, to act as Deputy to the Director of the organization and, in particular, to be responsible to him for the development and coordination of the programme of research carried out by the Organization's scientific departments—The Secretary, Hill Farming Research Organization, 48 Palmerston Place, Edinburgh 12 (December 31)

Assistant Lecturer or Lecturer in Physics—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (January 2)

Reader in Medical Microbiology at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (January 15)

Lecturer or Assistant Lecturer in Psychology—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (Janaury 16)

Senior Lecturer and a Lecturer in Mathematics at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (January 29)

Administrative Assistant (male science graduate (preferably physicist) not more than 35 years old, and interested in space research) with the Secretariat of the British National Committee on Space Research—The Assistant Secretary, Royal Society, Burlington House, Piccadilly, London, W 1

Area Chemist (with high academic and/or professional qualifications, good general experience of modern analytical methods, and preferably well versed in the technology of lubricating oils and greases —The Director of Research (British Railways), British Transport Commission, 222 Marylebone Road, London, N W 1

Biologist (with a good honours degree in zoology and/or botany, preferably a knowledge of both subjects and some postgraduate experience) with the Fauna Research Unit, Kenya, to carry out research on Kenya fauna to provide data for the building up of life tables , details of feeding habits, enemies, predators and diseases—The Director of Recruitment, Colonial Office, London, S W 1, quoting Ref No BCD 61/7/09/C1

Botanist (Plant Pathologist) (with a good honours degree in botany or agricultural botany, and at least two years postgraduate experience in plant pathology) in the Department of Agriculture, Uganda, to diagnose the cause of crop diseases and recommend control measures, and to assist with the breeding of disease-resistant crops—The Director of Recruitment, Colonial Office, London, S W 1 quoting Ref No BCD 63/9/02/C1

Entomologist, Scientific or Senior Scientific Officer (with a good honours degree in zoology with postgraduate training or experience in entomology) at the West African Cocoa Research Institute, Ghana, for research on insect pests of cocoa—The Director of Recruitment, Colonial Office, London, S W 1, quoting Ref No BCD 197/200/02/C1

Gross Anatomist (with research interests preferably, but not exclusively, either in electron microscopy or optical (especially interference) microscopy)—The Chairman, Department of Anatomy, Emory University, Atlanta 22, Georgia, U S A

Irrigation Research Officer (with a university degree in agriculture or a science degree with agricultural experience, and training or experience in soil physics or irrigation) in Swaziland, to carry out irrigation experiments on sugar cane, citrus and other crops, and to take charge of a new experimental station—The Director of Recruitment, Colonial Office, London, S W 1, quoting BCD 63/76/014/T

Laboratory Technician (able to work with the minimum of supervision, a sound knowledge of chemistry, and some experience of biological techniques)—The Administrator, Department of Biochemistry, The University, South Parks Road, Oxford

Lecturer (well qualified physicist, and preferably with experience of the application of physics in industry) **in Physics**—The Registrar, Bradford Institute of Technology, Bradford 7

Master to teach Chemistry, principally in the Sixth Form, up to scholarship standard, with some Middle School work—The Headmaster, University College School, Frognal, Hampstead, London, N W 3

Plastics Chemist or Plastics Technologist in the Department of Materials, to assist in the organization and supervision of the teaching laboratories and to participate in the research activities of the plastics group—The Registrar, The College of Aeronautics, Cranfield, Bletchley, Bucks

Technician or Senior Technician in the Zoology Department—The Secretary, Royal Holloway College (University of London), Englefield Green, Surrey

Technician (preferably with previous experience in bacteriological work), to work in the Virus Research Laboratory at Lodge Moor Hospital—Prof C H Stuart-Harris, The Royal Hospital, Sheffield 1

TAXATION OF LEARNED AND PROFESSIONAL SOCIETIES IN BRITAIN

DURING the past two decades, the professional and learned societies have encountered increasing financial difficulties. The major institutions no longer possess the intimate and social character that once was theirs, and this may well be one factor that has encouraged the proliferation of specialist societies with only a limited range of interests. Nevertheless, even those with a membership of several thousands have encountered difficulties in maintaining the publication of professional periodicals, and this is a matter to which the Nuffield Foundation has given some attention since 1955, in co-operation with the Royal Society for scientific periodicals, and the British Academy for periodicals in the humanities. Moreover, there appears to be a marked reluctance on the part of younger scientists and technologists to join the more general societies; the tendency is to support institutions the membership of which constitutes a professional qualification.

It is probably too early to assess as yet the effect of the concession made in the Finance Act last year which allowed fees and subscriptions to professional bodies, learned societies, etc., not of a mainly local character to be claimed as expenses against income tax. When this clause was considered in the House of Commons on June 17, 1958, the Financial Secretary to the Treasury explained that while there was no logical reason to exclude the local societies, to include them would place an administrative burden on the Inland Revenue out of all proportion to the relief to the taxpayer. It was estimated that the national societies alone probably numbered about 3,000, and since the subscriptions to the local societies were usually small, the cost to the general body of taxpayers was not consonant with any relief to the individual.

During the past year, the Inland Revenue has examined the activities of the national societies in the light of the new clause, and most of the societies have already been able to notify their members that they are in a position to claim relief. If it could be shown that the membership of these societies has appreciably benefited from this concession, it might be reasonable to re-open the question of the local societies and, with the position of the national societies already clarified, the Inland Revenue should not find it an unreasonable task to deal with the local learned societies.

To the professional and learned societies, however, the effect of this concession is unlikely to be great; its main benefit is to the individual member. The concession is important, so far as the societies are concerned, in helping to offset a number of adverse factors against which most of them have been struggling: stationary or declining membership (in spite of the increasing numbers of scientists and technologists), mounting costs of printing and publication, and the steady rise in postal charges. Some of these factors could be offset by a measure of rationalization, and the pilot survey of the publishing and distribution practices of the learned periodicals carried out by Mr. Robert Lusty on behalf of the Nuffield Foundation may be regarded as a step in this direction.

A much more serious matter for the learned societies and professional institutions is, however, the complexity of rulings about the payments they make to local authorities in the form of rates. During the past three years or more, the Parliamentary and Scientific Committee has made repeated representations to the Government on this matter, submitting, for example, a comprehensive memorandum to the Minister of Housing and Local Government directing attention to anomalies in the rating of both scientific societies and research associations. During the second reading debate of the Local Government Bill in the House of Commons on December 9, 1957, the Minister announced that he intended to set up a committee to give special consideration to the rating of charities and similar organizations, and the chairman of the Parliamentary and Scientific Committee was eventually informed that the terms of reference of this committee would be wide enough to permit consideration of the special position of scientific institutions.

This committee was, in fact, appointed on January 22, 1958, under the chairmanship of Sir Fred Pritchard, "To review the present treatment for rating of hereditaments in England and Wales occupied for purposes of a charitable nature or for other similar purposes (other than hereditaments to which Section 7 of the Rating and Valuation (Miscellaneous Provisions) Act, 1955, applies), to consider in particular the provisions of Section 8 of the Act of 1955 and of the Scientific Societies Act, 1843, and to advise on the proper treatment for rating of the hereditaments within these terms of reference". The Parliamentary and Scientific Committee submitted a memorandum on the general lines of that previously submitted to the Minister of Housing and Local Government and was later invited to submit oral evidence; only the Royal Society also gave oral evidence.

The report of this Committee*, which was presented to Parliament in August 1959, is of considerable general scientific interest, quite apart from the specific recommendations and their effect on scientific or professional societies. It should be remembered that rates are the main source of revenue within the direct control of local authorities, and it is the occupier rather than the owner of a hereditament who is ratable in respect of it. The earliest general enactment still extant which exempts a specific class of hereditament from rates is Section 1 of the Scientific Societies Act, 1843, which covers societies instituted for the purposes of science, literature or the fine arts. This section exempts such societies from rates if these societies are supported wholly or in part by annual voluntary subscriptions and do not make any dividend or bonus to their members. It would seem that in granting such exemption, Parliament intended to do no more than put the buildings of such societies on a par with buildings dedicated to public purposes.

---

* Report of the Committee on the Rating of Charities and Kindred Bodies. Pp. iv+86. (Cmnd. 831.) (London: H.M. Stationery Office, 1959.) 5s. net.

The commonest ground for loss or refusal of exemption has been failure to comply with the condition about support by annual voluntary contributions, and in reviewing the working of the Act, the Committee gives most attention to this condition, which has led to a good deal of litigation and is still not entirely clear. It appears that income from invested voluntary contributions is not itself an annual voluntary contribution and, in consequence, a society which depends almost entirely upon voluntary contributions but accumulates trust funds for prizes, exhibitions or scholarships could ultimately be disqualified because the investment income from contributions, although undoubtedly voluntary, was too large in relation to current activities. Moreover, the Committee could often see no difference between societies within and those without the exemption, and several societies now exempt appear to be fundamentally different from the kind of institution which members of Parliament who supported the Bill in 1843 appear to have had in mind.

The Committee was agreed that the provision could not be left unchanged, and because wherever the line were drawn there would be anomalies at the margin and any re-drafting of the conditions precedent to exemption would give rise to fresh litigation, the Committee invited the Royal Society and the Parliamentary and Scientific Committee to give oral evidence. The Committee was not, however, satisfied that any of the societies had a better claim to exemption than other charities. Most of them would be entitled under the Committee's other recommendations to 50 per cent mandatory relief as charities and, accordingly, the Committee recommended that the Scientific Societies Act of 1843 should be repealed.

Nevertheless, the Committee, like the Sorn Committee which reported in September 1954 on the Scottish rating system, recognizes that to withdraw abruptly the exemption under the Scientific Societies Act, 1843, might cause undue disturbance to the finances of the bodies concerned. It suggests, therefore, that in the first full financial year after the repeal of the provision none of the societies which was a beneficiary under it at the date of repeal should be liable for rates in respect of hereditaments which were exempt at that date. In the second year, the rates which, apart from the transitional arrangements, would have been payable by the societies concerned should be abated by four-fifths, and in the third year by three-fifths, in the fourth year by two-fifths, and in the fifth year by one-fifth. A scientific society would thus not be liable for the full 50 per cent until the sixth and subsequent years, while if it was not a charity it would pay 20 per cent in the second and 40 per cent in the third, rising to full rates in the sixth and subsequent years.

The Committee shares the general view of its witnesses that Section 8 of the Rating and Valuation (Miscellaneous Provisions) Act, 1955, which governs the rates payable by charitable and other organizations, is unacceptable as a permanent provision, and it sees no justification for giving permanent rate relief to all organizations in so wide a field. It considers that the time has come to introduce a measure of uniformity and certainty into the rating relief enjoyed by bodies within its terms of reference, and that a satisfactory scheme should be simple and economical to administer and should not add materially to the rates borne by other classes of rate-payer. Its essential basis should be mandatory relief for the great majority of the classes of organization which in the past have enjoyed some measure of relief.

It recommends accordingly that charities should have mandatory relief and that, although the decision as to the amount must be to a considerable degree arbitrary, relief of 50 per cent strikes a reasonable balance. It does not consider that there is any need to re-define the term 'charity' for rating purposes only, and in the White Paper outlining its policy on Charitable Trusts in July 1955, the Government rejected proposals for a new definition for general purposes. The Committee recommends that organizations on the fringe of the field of charity should be eligible for relief at the discretion of the local authorities, but it does not recommend that charities in general should be excluded from relief on the ground that the body is national or that it is in receipt of Exchequer grant or fees or because its voluntary income is small. The position of the universities was specially considered, but the Committee does not consider that, on balance, the exclusion of all university institutions would be justified by the evidence or arguments presented.

Representations were made to the Committee that a new statutory relief of 75 per cent should be allowed to industrial research associations, and on this also oral evidence has been heard from the Parliamentary and Scientific Committee. The Pritchard Committee, however, submits reasonably enough that research associations are much more akin to the research establishments of individual firms than to charities, and that the relief considered appropriate for research establishments conducted by individual firms within the curtilage of their industrial hereditaments should be extended to the premises of industrial research associations. This view is in accordance with that expressed in evidence by the Department of Scientific and Industrial Research.

No pronouncement has yet been made by the Government regarding its acceptance or otherwise of the recommendations of the Pritchard Committee; this matter of rating relief is only one way in which Section 8 of the Rating and Valuation (Miscellaneous

Provisions) Act, 1955, has touched the scientific and other learned societies very closely. Under the Local Government Act, 1948, valuation officers of the Board of Inland Revenue became responsible for valuation rating on February 1, 1950, with the object of securing uniform standards of valuation, and this, of course, precluded the continuation of the practice of sympathetically undervaluing hereditaments occupied by charities and kindred bodies Section 8 of the Rating and Valuation (Miscellaneous Provisions) Bill introduced in March 1955 was intended to avoid the substantial increases in liabilities for rates which such bodies would otherwise have incurred, and it was quite clear in the debates on the Bill, which received Royal Assent on July 27, 1955, that the Government fully appreciated the difficulties of the scientific and learned societies.

The Pritchard Committee in its report emphasizes that this Section of the Act provides the first statutory relief from rates for charities as such, and the first endorsement by Parliament of the relief previously given extra-statutorily by local government in various ways Further, this element of mandatory relief was introduced by the Government not, initially, as a matter of Government policy, but in deference to the wishes of the House of Commons after a provision relying entirely upon local discretion had been criticized from all quarters Moreover, this particular enactment was designed as a holding provision and never intended as a permanent arrangement.

These observations are important, as they indicate clearly the line which should be taken by scientific societies and professional organizations which may be unfairly affected in the new situation It follows, moreover, that legislation to provide some reasonable permanent arrangement is not merely probable but almost inevitable, and that it is in the debates on such legislation that the needs of the scientific and learned societies and professional organizations should be clearly and effectively presented to Parliament.

When in 1950 the valuation officers of the Board of Inland Revenue assumed responsibility for valuation for rating, they did not disturb the exemptions in the old lists unless they were asked to do so by the rating authorities , but in preparing the new valuation lists which came into force on April 1, 1956, they applied strictly the provisions of the Act of 1843 as recently interpreted by the courts In consequence, some societies which had been exempt became liable for rates on assessments based on full current rental values, and only some of those which challenged this liability in the courts succeeded Further, the Board of Inland Revenue has suspended the income tax rebate which the learned societies enjoyed on seven-year covenants entered into by their members, and for some of them has finally withdrawn the relief

This is the second aspect of the situation which deeply concerns the professional associations and learned societies and other bodies, and may affect some of them much more seriously than the concession made regarding subscriptions to such bodies in Clause 14 of the Finance Bill, 1958 Indeed, although the situation is complex and is still being argued between various bodies and the Inland Revenue, sometimes in the Court of Appeal, it would appear that those bodies which have lost the right to tax rebates on subscription income guaranteed from covenants are likely also to lose rating relief and the advantage of their members being able to claim subscriptions as expenses against income tax Probably it is not too much to say that some of the societies have only been able to meet post-war costs through the rebates in covenanted subscriptions and relief from rates which they have hitherto enjoyed

The Pritchard Committee argues lucidly and cogently for a mandatory and uniform system of rating relief It does not suggest that all anomalies will be removed or that there should be no discretionary relief It is difficult to refute the argument of an eminently sensible report, but before adopting the legislation to which the report points, Parliament might reasonably re-examine the fundamental question what is a charity for tax purposes, and especially the full and wide implications of what could not unfairly be described as an assault on learned societies launched by the Board of Inland Revenue Parliament at least, should be concerned not so much with the benefits and advantages, to particular institutions and their members, of taxation or rating relief, but with the extent to which the public interest is served by such bodies A recent survey of leisure and learning in Bolton and Rochdale pointed to the value of such societies in the world of to-day, quite apart from their place in the dissemination of knowledge and the maintenance of professional standards, and to their need of assistance in the maintenance and equipment of premises The place of the scientific and learned society in the world of to-day could be appropriately re-examined in the light of all the implications of the situation on which the Pritchard Committee has now reported

KEW, PAST AND PRESENT

The Royal Botanic Gardens, Kew

By W B Turrill Pp 256+16 plates (London Herbert Jenkins, Ltd , 1959) 25*s* net

"KEW" to botanists, horticulturists and admirers of plants the world over is the Royal Botanic Gardens, Kew, Richmond, Surrey, England Like many other famous places or institutions, the exact day of its founding is uncertain This summer, however, the Royal Botanic Gardens celebrated a birthday of approximately two hundred historic, profitable, eventful and beautiful years At this occasion grateful botanists paid tribute by manuscript, letter or personal visit Few have honoured Kew as well, though, as William Bertram Turrill does in this book It is a devoted tribute to the Gardens the author knew and served for forty-nine years until his retirement in 1957

"The Royal Botanic Gardens, Kew" is both a historical account of the development of the Gardens and laboratories and a detailed description of their current contents The book is readable, but the historical portion and that of current activities of the staff are written with so much under-statement that one longs for greater emphasis on the personality and procedures of the men who made Kew and contribute to its reputation to-day. The Royal Botanic Gardens have served as a training ground for many scientists, explorers and gardeners, but Dr. Turrill is almost reluctant in admitting the contributions of these men. Procedures, ideas and even the architecture developed at Kew were taken by students to distant lands, and one sees the influence of Kew in some aspect of every major herbarium and botanic garden of the world. A single chapter of a scant fourteen pages describes the current scientific research of nearly eighty-five people. Three pages are devoted to "Plant Introductions via Kew", and nearly half of this concerns the story of quinine. One wishes Dr. Turrill had elaborated more the credit which is due to the activities and leadership of Kew, and in basic research and practical horticulture.

The remaining chapters, particularly those on "Economic Botany and the Kew Museums", 'The Greenhouses" and Kew at various seasons, charmingly describe a tour of the exhibits, living and preserved, in infinite detail. The book will serve as a guide, supplying, where appropriate, the personal exposition of a tour leader on how trees grow or manufacture food, or how plant products are used, or where particular plants can be found. One familiar with museum and garden exhibition techniques visualizes in Turrill's account both the display and the information on the labels. At the same time, the casual reader may be unaware that chapters of a basic text-book of botany have been paraphrased to present briefly and clearly the reasons for the exhibit.

A chapter on "Wild Life at Kew" exemplifies the detail of the book in relating much information, including the introduction of the American grey squirrel and its destruction, the amount of myxomatosis in the rabbits of Kew during the year 1955, the types of weeds in the lawn or the record-sized fish caught in a Kew pond and its present location. Throughout this and other chapters are the intimate stories one gets in a personally conducted, leisurely tour by a guide who knows and loves the Royal Botanic Gardens, Kew.

Sixteen excellent plates illustrate the men and women responsible for Kew's past, the present buildings, and scenes from the Gardens. Appendixes give details on the climate, the rules and regulations, the physical plant, the composition of the staff and the chronology of the curators and keepers of the Herbarium, Library and museums. A bibliography of sixty-six titles relating to Kew, an index and a grid map, referred to frequently in the text, complete the book.

As one enjoys a garden at many hours of many seasons, so I recommend to past, present and future friends of Kew a leisurely and frequent reading of this book. RICHARD A. HOWARD

JET PROPULSION

Jets and Rockets

By A. Barker, T. R. F. Nonweiler and R. Smelt. Pp. xiv+268. (London: Chapman and Hall, Ltd., 1959.) 35*s*. net.

THE history of this book prior to publication was unusually rich, and Mr. Nonweiler recites it with relish in his candid preface. The book was begun by Mr. Smelt in 1945, and then passed to Mr. Nonweiler after the former 'went West to the States'; finally Mr. Barker brought it up to date and completed it. Although a few authentic touches of antiquity survive, most of the book has been satisfactorily modernized, and the reader need have only occasional qualms on this score.

The book is intended as an introductory text-book on all forms of jet propulsion, rocket, ramjet, turbo-jet, pulse-jet and various hybrids, and on the whole, it achieves this purpose well. The authors describe clearly the main features of each power plant, and preserve a fair balance; they do not delve very deeply into the specialized problems of each engine, but this cannot be expected in a 250-page book so wide in its scope. The chemistry of rocket combustion and the thermodynamics of the various engines—the theory underlying the calculation of thrust coefficient and fuel consumption—are presented in adequate detail; and the methods of calculating drag and the design of air intakes are also thoroughly discussed. One of the best features of the book is its emphasis on the close links between the internal thermodynamics of an engine and its external aerodynamics. This emphasis is particularly valuable because many text-books on propulsion tend to ignore the external aerodynamics, although minimizing drag can be just as important as maximizing thrust, especially at supersonic speeds.

Unfortunately, the book is marred by lack of attention to detail. Several of the formulæ are in error (e.g., equations 5.13 and 5.15), some of the graphs lack units, the spelling is erratic, misprints abound and there are many stylistic lapses. Chapter 15 is in places sadly out of date: it gives the impression that the V2 was the ultimate in rocket missiles and that space vehicles are virtually impossible. Indeed, throughout the book, German war-time engines, now museum-pieces, are too often quoted as examples, thus giving the false impression that the accompanying text is equally obsolete. On one point of detail the book is excellent: there are more than 120 diagrams and photographs, most of them pertinent, clear and informative.

D. G. KING-HELE

NUCLEAR FUEL TREATMENT

Chemical Processing of Nuclear Fuels

By Dr. F. S. Martin and Dr. G. L. Miles. Pp. x+242. (London: Butterworths Scientific Publications; New York: Academic Press, Inc., 1958.) 40*s*.; 7.50 dollars.

ALTHOUGH this book is intended mainly as an introduction to the problems of chemical processing of nuclear fuel after irradiation in a reactor, its scope extends much further. In Part 1, which deals with "Nuclear Considerations", the three main systems uranium-235, uranium-238–plutonium and thorium–uranium-233 are considered separately and the reactions occurring under thermal neutron irradiation shown diagrammatically.

The several highly developed solvent-extraction processes employed in nuclear processing are described and decontamination factors listed. The requirements of a process for purifying the plutonium product of primary separation are also enumerated and the value quoted for the overall recovery of plutonium (99.4 per cent) in one process shows how highly developed this particular technology has become.

In the middle chapters, the authors survey other processes which have been considered (and in some cases developed) for the separation of heavy nuclides from fission products The range covered is sufficient to indicate the amazing volume of research which has been carried out on both sides of the Atlantic in this field—ion-exchange separations, metal distillations, halide volatilizations, extractions by molten metals, purification by slagging processes, extraction by fused chlorides as well as the more conventional (and historically important) processes of separation by precipitation

There is also a section in the book dealing with the disposal of effluents and fission product recovery, a field which has received much attention from authors, both knowledgeable and otherwise, in recent years It is sufficient to say that the treatment here is brief and chemically factual and scores on both these counts

A criticism which may be advanced, perhaps, is that the reader is not given very clearly to understand which are the most important separation processes described The dominant position now held by solvent extraction processes and the resultant commercial difficulties in the way of any competing technology are not brought out very fully But such an appreciation is not necessarily a function of this book, it is abundantly clear that it represents a valuable and important contribution to chemical literature It should find its way not only to those science and engineering graduates with some acquaintance of nuclear reactor development but also to that much wider reading public of chemists and chemical engineers who would like to read and have by them an authoritative and interesting work on the applied chemistry of nuclear power J E LITTLECHILD

FOOD ANALYSIS

The Chemical Analysis of Foods and Food Products

By Dr Morris B Jacobs Third edition Pp xxiv + 970 (Princeton, N J D Van Nostrand Company, Inc ; London D Van Nostrand Company, Ltd, 1958) 103*s* 6*d*

THE 970 pages of this book include more material than the title indicates The text includes information on the make-up of several types of food For example, the chapter on sugar foods and carbohydrates begins with a useful summary of the types of carbohydrates found in foods, the chapter on meat gives definitions of meat products and tables of typical compositions, the chapter on oils and fats contains in tabular form information on 24 fatty acids, the chapter on quality measurement includes a general introduction on flavour acceptance, while the chapter on milk comprises more than a hundred pages and includes detailed information on composition, on cheese and other products, and on adulterants

Essentially, however, the work is a practical book for use at the bench The book begins by describing general chemical and physical methods that are used in the analyses of food products Directions are given for analysing constituents of all common and some less common foods The book also includes chapters on undesirable materials in food For example, one chapter deals with filth, and includes working directions for estimating the amount of rodent excreta, maggots, rancidity, and decomposition in fish and other foods There are also chapters on pesticide residues, radiochemical determinations, food poisoning and preservatives The detection of horse meat in presence of other animal tissues is discussed Chapters are included on artificial sweetening agents and on colouring matters Instructions are even given for such details as how to count the pits in preserved cherries from which the pits have ostensibly been removed

In a few respects—for example, in spectrophotometry, in absence of mention of methyl cellulose, in determination of tocopherols and of carotene, in lack of reference to paper chromatography—the book is not up to date, but it would be impossible for so large a work to be kept up-to-the-minute by one author The book has been produced in the United States and is primarily concerned with codes of practice and food laws in that country, but in nearly all cases the information has general application The book is indeed a useful compilation

V H BOOTH

A FLORA OF THE ARCTIC

Circumpolar Arctic Flora

By Nicholas Polunin Pp xxviii+514 (Oxford: Clarendon Press, London Oxford University Press, 1959) 126*s* net

TWO problems immediately confront those who write on arctic plants first, the difficulty of defining the limits of what one proposes to term 'the Arctic', and secondly, the even greater difficulty of providing an adequate and up-to-date account of that vast and virtually inaccessible area lying east of Finland and west of the Bering straits Dr Polunin with his extensive experience of the arctic and arctic vegetation faces up boldly to the first problem and can no doubt furnish weighty arguments in favour of what appears to be a curiously involved, indeed almost tortuous, delimitation As regards the second problem, the author freely admits that our knowledge of the Soviet arctic is inadequate, and that, in present circumstances, no Western or American botanist can hope to compile a detailed and critical circumpolar flora Some may feel, this being so, that any attempt to deal with the flora of the area is bound to be premature and unsatisfactory The number of flowering plants and vascular cryptogams occurring in the Arctic is so small that the critic has some right to expect a minute and detailed analysis, and to be more exacting in his demands than if the author were attempting a survey of some tropical region with a richly diversified flora If the reader approaches Dr Polunin's book in this frame of mind he will find much to criticize, for the very frequent use of the tell-tale abbreviations *agg* and *s l* after the scientific names shows how much has still to be done before the last word can be written on this subject But half a loaf is better than no bread, and the less exacting will be glad that Dr Polunin has had the energy and enterprise to give us a concise, lavishly illustrated and, for practical purposes, a tolerably complete account of these northern plants

British botanists, whose thoughts turn not infrequently to those epochs when much of Great Britain lay buried under ice and snow, will be intrigued to see how many truly arctic species still survive from those bygone glaciations, and (bearing in mind recent records of *Koenigia, Diapensia* and *Artemisia norvegica*) some may choose to ruminate on the number and likely identity of species yet to be discovered here. Palynologists, geologists and archæologists will also find, in these pages, the sort of information that can save hours of exhausting work in the identification of doubtful grains or fragments. Two features that will certainly not be commended by botanists are the absence of author citations in the main body of the text, and the invention of popular names, some of which (for example, "Boreal Blinking-chickweed") would, in a less august environment, raise a laugh. It is a pity, too, that space should have been devoted to derivations of generic names; such learning is scarcely called for in a book of this sort. The illustrations, though uneven in quality, are on the whole very pleasant to look at, and sufficiently detailed to give us a very fair idea of each plant. Printing and format are excellent, though the regrettably high price must necessarily put the book beyond the means of many who would be happy to possess it.

R. D. MEIKLE

NEW IDEAS FOR INDUSTRY

Investment in Innovation

By C. F. Carter and B. R. Williams. Pp. ix+167. (London: Oxford University Press, 1958.) 15*s*. net.

THIS book is in effect a supplement to the same authors' work on industry and technical progress, being in the main a by-product of the case studies which were undertaken in connexion with the writing of that book under the auspices of the British Association and the Conditional Aid scheme. It is a detailed investigation, based upon case material, of the reasons why firms invest or do not invest in technical innovations. Perhaps the only brief statement that can be made about its conclusions is that it shows the enormous range of difference between firms and industries in the nature of the incentives to investment. Thus, for example, it is made clear that, in some cases, keener competition at home or abroad is an incentive to investment while in other cases protection from competition will have this effect. The effect of excess demand manifesting itself in long order books is also noted as one of the factors that have been important in some cases in recent years, and there is a careful discussion of the effect of fiscal changes in stimulating either new investment or quicker replacement of plant. The general factors which are regarded as likely to promote accelerated investment in innovations most effectively, however, seem to be the supply and wide diffusion through industry of scientifically literate people and the improvement of recruitment and training for management. It is essentially effective access to information about new technical possibilities and the willingness and ability to introduce change without creating insuperable opposition that seem to be key factors in determining the rate of industrial progress.

Not very much attention is given by the authors to the supply of capital as a factor limiting investment of the relevant kind, though they found some cases in which shortage of risk capital had been important. Their investigation, however, throws more light on the old question whether interest rate is an important controlling factor governing industrial investment. In general, they conclude from their field studies that with interest rates varying over the normal range their direct influence is slight—investment projects are either so attractive that a difference in interest rate between, say, 2 and 6 per cent will have little effect upon them or so unattractive that they will not be undertaken at any interest rate however low. The authors think, however, that there is an intermediate class of projects to which the rate of interest is critical even as things are, and that this class might be much bigger if interest rates were capable of going higher than in fact they have gone in advanced countries in modern times.

Altogether this is an extremely valuable and stimulating book belonging to the select but growing class of contributions to economics which seek answers to the really fundamental questions from direct investigation of industrial life.

A. J. BROWN

THE FUTURE OF THE ETRUSCANS

Ciba Foundation Symposium on Medical Biology and Etruscan Origins

Edited by G. E. W. Wolstenholme and Cecilia M. O'Connor. Pp. xii+255. (London: J. and A. Churchill, Ltd., 1959.) 45*s*. net.

THE publication of a Ciba Foundation symposium is always an interesting event. This volume has a stimulating title; the synthesis attempted is an innovation of some significance, and it will be viewed from many quarters with a critical eye, in order to assess the value of its application to populations other than the Etruscans.

The Foundation must be congratulated on having drawn together a group of eminent scientists and Etruscologists, and on the clear layout and attractive presentation of the volume. The illustrations show evidence of a care not always extended to the maps. The first five papers presented at the symposium give the evidence of archæology, religion and linguistics, and some space is given to discussion of the varying theories on the origins of the Etruscans which this evidence permits. As Prof. Banti points out, no one theory can be held dogmatically on the basis of the present information from these fields; and for this reason if for no other, much might be expected of the contributions of the scientists to this meeting. If, in the conclusions which may be drawn from it, the second section falls short of the reader's expectations, it must be borne in mind that the value of scientific work to such studies has only recently been appreciated; indeed, this is made clear in the discussions, in which it is admitted that skeletal material has received cavalier treatment in the past. The main value of this meeting of scientists and archæologists lies in its promise, and in the opportunity it has provided to discuss mutual requirements; many interesting possibilities are outlined by the various speakers, not the least of which is that of the blood grouping of skeletal remains. Several speakers discuss the serology of the modern population of Etruria; a feature the impact of which is somewhat spoilt by the failure of the historians to show that this region has remained genetically isolated since the Etruscan period.

This book presents an intriguing approach to an old and fascinating problem, and much can be gained from its careful outline of the requirements and pitfalls of such studies. It is likely to become a useful reference book.

MADELEINE SMITH

Khami Ruins

Report on Excavations undertaken for the Commission for the Preservation of Natural and Historical Monuments and Relics, Southern Rhodesia, 1947–1955 By K R Robinson With Reports by G Bond and E Voce Pp xvi+192+28 plates (Cambridge At the University Press, 1959) 40s net

IT seems likely that iron-working, agriculture and the manufacture of well-made pottery reached Central Africa at the same time and as elements of the same culture complex, within a century or two of the beginning of the Christian era The event marks the beginning of the history of the Bantu-speaking peoples in the area, and forms a most important field of pre- and proto-historical research None the less it is a sadly neglected field of study, and much credit must go to prehistorians working on this period in Southern Rhodesia

Miss Caton-Thompson's work on Zimbabwe is well known, and earlier this year Roger Summers produced a most important book on the terraces and ruins of Inyanga Keith Robinson's excellent book on the Khami ruins now enables us to make some sense of the third of the great ruins sites of Southern Rhodesia

The book is an excellent objective study of the ruins based on many years of intimate study, backed by carefully selected excavation It is attractively set out, with good illustrations, and in Chapter 5 the conclusions are logically and clearly presented The over-riding weakness in all three of the works mentioned is the lack of conclusive dating evidence This is no fault of the writers concerned and is entirely due to the difficult nature of the evidence Radiocarbon dates are urgently needed

It is to be hoped that the future will see a continuation of the excellent work now being done in Southern Rhodesia, perhaps, we may add, with rather more emphasis on the crucial earlier phases of the Rhodesian Iron Age R R INSKEEP

Rock Pressure in Mines

By E de St Q Isaacson Pp x+212 (London: Mining Publications, Ltd , 1958) 45s

SEVENTY-FIVE years ago Fayol published results of his investigations into ground failure While his conclusions were valid at shallow depths, it was found that at deeper levels stresses, which had little significance near the surface, began to play an ever-increasing part During the past thirty years many workers have investigated the problem, and in "Rock Pressure in Mines" we have a comprehensive account of the theoretical and practical principles that govern the behaviour of pressure in underground workings The author, who is in charge of the Rockburst Research Unit of the Kolar Gold Mines, devotes the first four chapters to theoretical considerations, dealing with elastic stresses and strains, elastic stresses in isotropic rocks around differently shaped excavations, the behaviour of rock stressed beyond the elastic limit, and modifications due to departures from homogeneity He then applies these considerations to the planning and lay-out of workings In a chapter on rock-bursts he shows how strain energy may be built up He considers that good planning coupled with destressing should substantially reduce the danger of rock-bursts Descriptions and criticisms of several occurrences are given Finally, some of the instruments suitable for measurement of stresses and strain underground are described The book is well planned and pleasingly written There are 125 simple line-drawings and some plates References to standard text-books and technical papers are adequate It is a book which will be invaluable to all who are concerned with problems of rock pressure

Plant Nematodes

Their Bionomics and Control By Dr Jesse R Christie Pp xi+256 (Gainesville, Fla Agricultural Experiment Stations, University of Florida, 1959) 3 75 dollars

NEMATOLOGY as a separate discipline is a relatively recent development and, as a result, the information on the bionomics and control of plant parasitic nematodes is spread widely through technical journals and bulletins This literature has not only been surveyed and compiled by the author but is also presented in a clear and logical manner The author of this relatively small book has succeeded admirably in fulfilling his declared intention of writing a work for specialists which is also understandable to others generally interested in agriculture and horticulture This he has done in fourteen chapters of which the first is a general introduction to nematodes and nematology, while the second is a general discussion of the principles of nematode control Each of the remaining chapters deals with one group of related nematodes and each is laid out in the same sequence, so far as the subject-matter will allow First, the taxonomy of the parasite, then the life-history and habits, the injury caused to the host, a list of hosts, the parasites' known distribution and methods of spread, and, finally, methods of control Five tables, in an appendix, list the parasites and their distribution, under the crop plants attacked, control measures, details of hot-water treatments, the common names of plant parasitic nematodes, and in the fifth table a list of scientific names of nematodes attacking plants, and their synonymies, is given The symptoms resulting from nematode attack are illustrated by photographs which are generally of a high standard The book should form a useful source of reference to experienced workers as well as a text-book for the student W G INGLIS

Acetophenetidin

A Critical Bibliographic Review By Prof Paul K. Smith (Monographs of the Institute for the Study of Analgesic and Sedative Drugs, No 4) Pp x+180 (New York Interscience Publishers, Inc , London Interscience Publishers, Ltd , 1958) 45s

P K SMITH'S book on acetophenetidin is the fourth in a series of monographs reviewing the literature on individual drugs It deals with 529 references on the clinical uses, pharmacological properties, metabolism and side-effects of acetophenetidin (phenacetin) and its metabolite N-acetyl-*p*-aminophenol The book throws an interesting light on the history of the use of antipyretics, and reflects the changes in medical thought on disease during the past seventy years If the purpose for which the drug is employed has changed, its popularity has stood the test of time, and justifiably so, since acetophenetidin is not only efficacious but virtually free from harmful side-effects Pharmacological work on the substance will continue, as we are far from understanding the reasons for its pain-relieving action MARTHE VOGT

A NEW EXPERIMENTAL TEST OF SPECIAL RELATIVITY

By J. P. CEDARHOLM
I.B.M. Watson Laboratory
AND
Prof. C. H. TOWNES
Columbia University, New York

EXPERIMENTS which have tested special relativity have usually been forced to rely on great delicacy and precision in order to detect or examine the small differences between predictions of special relativity and those of alternate theories. This is because these differences appear multiplied by a very small quantity $(v/c)^2$, where c is the velocity of light and v is some relative velocity which is generally much smaller than c. While giving a clear-cut support to special relativity over some other theories such as a simple ether, experiments have not generally measured the small terms in $(v/c)^2$ with impressive fractional accuracy. Michelson and Morley's first experiment[1], for example, was of remarkable precision. But it was searching for a change in light-path of only about one part in 10^8 due to the motion of the Earth about the Sun on the basis of the then current ether theory, and was able to set an upper limit no less than 1/40 of this, or an ether drift of about one-sixth the orbital velocity of the Earth. Subsequent very refined experiments[2] of a similar type succeeded, a half-century later, in setting an upper limit on any ether drift of 1/20 the velocity of the Earth around the Sun. Others[3] even suggested the existence of an ether drift as large as about one-fifth of the orbital velocity of the Earth. The advent of very high precision atomic clocks suggests that still more exacting experimental tests may now be made; one such, which is now more or less completed, is reported here.

The experiment compares the frequencies of two maser oscillators[4] with their beams of ammonia molecules pointed in opposite directions, but both parallel to a supposed direction of motion through the ether. If both masers are rotated 180°, and their frequencies again compared, a change in relative frequency should be found due to motion of the masers through the ether, assuming the molecular vibrations are unchanged by such motion. A precision of one part in 10^{12} has been achieved in this frequency comparison, and failure to find a frequency change of the predicted type allows setting the upper limit on an ether drift as low as 1/1,000 of the orbital velocity of the Earth. This precision also provides a test for some other effects which will be discussed below.

The effect on the frequency of a beam-type maser oscillator of motion through the ether was first worked out by Møller[5]. A brief, somewhat intuitive explanation of this shift follows. In this device, ammonia molecules in an excited state travel at thermal velocities along the axis of a circular cylindrical cavity, giving it energy. If the cavity is stationary in the ether, the standing waves may be considered to be made of travelling waves with wave-fronts nearly parallel to the axis. As the molecule moves along the axis, there is then no Doppler shift. If the apparatus is moving axially through the ether at velocity v, the wave-fronts must tilt at an angle $\alpha = v/c$ in order to follow this axial velocity. Hence, molecules travelling at velocity u through the cavity produce a frequency shifted by the Doppler effect of an amount $\nu u\alpha/c = \nu uv/c^2$. Here ν is the molecular frequency. Since $uv\nu/c^2$ depends on the relative direction of u and v, two masers with oppositely directed beams should have frequencies which differ by $2uv\nu/c^2$ due to this effect. If each is rotated 180°, the total change in their frequency difference is $4uv\nu/c^2$.

A more precise derivation of this effect is obtained from the fact that special relativity predicts the same result as does an ether theory, provided that the FitzGerald contraction $\sqrt{\left(1 - \frac{V^2}{c^2}\right)}$ is introduced for any length parallel to the motion v through the ether, and also that the proper time of any clock or oscillator is modified by the same factor $\sqrt{\left(1 - \frac{V^2}{c^2}\right)}$ due to this motion. In other words, any effect due to motion through a simple ether is just compensated by appropriate changes in scale for length and time which correspond to the Lorentz transformation. If, then, an ether theory is used without FitzGerald contraction and time dilation, the expected shift in frequency may be computed from an examination of the effects of these changes of scale for length and time.

Consider first the FitzGerald contraction. Its effect on the frequency of maser oscillation is very small and may be neglected because this frequency is rather insensitive to the dimensions and resonant frequency of the cavity[4].

The time dilation, however, produces the effect we seek. If the cavity moves through the ether at a velocity v and the molecule through the cavity at velocity u, then the molecular velocity through the ether is $V = u+v$, and the molecular time will be slow, for an observer in the framework of the ether, for the factor

$$\sqrt{\left\{1 - \frac{(u+v)^2}{c^2}\right\}} \approx 1 - \frac{u^2}{2c^2} - \frac{uv}{c^2} - \frac{v^2}{c^2}$$

But time in the actual laboratory framework, which is fixed with respect to the cavity, is slow by the factor

$$\sqrt{\left(1 - \frac{v^2}{c^2}\right)} \approx 1 - \frac{v^2}{2c^2}$$

Hence the molecule would appear slow to an observer in the laboratory by the difference between these two, or by the factor

$$1 - \frac{u^2}{2c^2} - \frac{uv}{c^2}$$

The first small correction is the well-known transverse Doppler effect, and is independent of ether drift The second small correction is the discrepancy uv/c^2 which would occur if we were to accept a simple ether and no time dilation in the proper oscillation of the molecule, as postulated in Møller's original discussion[5]

The above derivation makes it clear that failure to see any change in time equivalent to the small fractional amount uv/c^2 may be explained away by the assumption of a time dilation for those who wish to adhere to an ether with such peculiarities Hence the experiment is more closely related to the Kennedy–Thorndike experiment[6] than to that of Michelson and Morley A null result in the latter needs, of course, only a FitzGerald contraction for an explanation in terms of an ether theory

For performance of the present experiment, two ammonia beam masers were mounted with oppositely directed beams on a rack which rotated about a vertical axis The frequencies of these oscillators are near 23,870 Mc /s The thermal velocity $u =$ 0 6 km /s for NH_3 at room temperature If the orbital velocity of the Earth is assumed to be the rate of motion through the ether, then $v = 30$ km /s and the frequency change $4uv\nu/c^2 = 20$ c /s when the masers are rotated 180° from an initial east–west position at noon or midnight

During a small fraction of a second the relative frequency of the two masers fluctuates randomly about $\frac{1}{10}$ c /s Over somewhat longer periods, such as those required for measurement before and after rotation, the average frequency difference does not vary more than about $\frac{1}{50}$ c /s or one part in 10^{12}. Hence the 20 c /s variation expected on an ether theory would be very easily detected Variation of about 1 c /s on rotation of the two masers was in fact observed However, this variation could be eliminated by magnetically shielding the masers, and without shielding it remained constant to within about $\frac{1}{50}$ c /s as the Earth rotated throughout a 24-hr run This shows that no more than about $\frac{1}{50}$ c /s shift could be attributed to an ether drift

The experiment involving rotation of the two masers was carefully done for the first time on September 20, 1958[7] No proper effect as large as $\frac{1}{50}$ c /s was found Hence, since the orbital velocity of the Earth of 30 km /s would have given an effect of 20 c /s , the ether drift could not have been larger than 1/1,000 of this value, or 30 m /s It is, of course, possible for the motion of the Earth to be just cancelled by the motion of the solar system through the ether at some particular time of the year The experiment has now been repeated at the Watson Laboratory during 24-hr runs at approximately three-month intervals throughout the year In none of these runs was any effect as large as $\frac{1}{50}$ c /s found

The present experiment sets an upper limit on an ether-drift velocity about one-fiftieth that allowed by previous experiments This is in part because the effect measured is linear in the ether drift velocity v An experiment of the Michelson–Morley type is designed to detect a fractional change of the form $\frac{1}{2}v^2/c^2$, which is an order of magnitude larger than the term uv/c^2 discussed here An upper limit of 1/400 of $\frac{1}{2}v^2c^2$ has been set by the very careful experiments of Joos[2] with a Michelson interferometer However, since this term is second order in v, the upper limit given for the ether-drift velocity is one-twentieth of the orbital velocity of the Earth, or 1 5 km /s The present experiments have the advantage that the expected effect is linear in v, and also that two clocks can now be compared with much greater precision than can two distances This experiment, involving a comparison of two maser oscillators to an accuracy of one part in 10^{12}, may perhaps represent the most precise experiment so far reported

For most physicists, a confirmation of the fundamental postulate of special relativity that no absolute motion can be detected comes as no surprise, and a more precise experimental test may not even seem important because this postulate is so intuitively satisfactory and firmly accepted It should be noted, however, that the positive detection of an effect in the present experiment could give some new information without necessarily contradicting the general principles of relativity The motion of the Earth involves velocity relative to other parts of the solar system, as well as to the fixed stars and external galaxies Hence this relative motion might, in principle, produce some anisotropy in space and some shift in relative frequency of the two masers when they are rotated by 180°

Dicke[8] has suggested that an effect due to motion with respect to fixed masses in the universe should be present which is of the order of the fine structure constant, α, times the effect due to ether drift This would correspond to a frequency shift in the present experiment of the order of $\frac{1}{7}$ c /s Reasons given by Dicke why such a shift might occur are speculative, but very interesting The present results allow no shift larger than $\frac{1}{50}$ c /s , which gives some indication against a term of the order $4\alpha uv\nu/c^2$

Optical maser oscillators[9] should also lend themselves to interesting experiments on relativity, since they will probably be capable of examining changes in length as small as one part in 10^{12} An optical maser oscillator could be constructed with a resonance between two étalon plates which is narrower in frequency than the atomic resonance supplying energy In this case the frequency would depend primarily on the spacing between the plates, rather than on the atomic frequency It is estimated that the oscillation would be monochromatic to about one part in 10^{11} This suggests an experiment in which the oscillations of two optical masers are beat together in a photocell One of the masers may be rotated about a vertical axis On the basis of an ether theory, the beat frequency should then vary by an amount $\pm\ v^2\nu/2c^2$, for the same reasons that the Michelson–Morley experiment was expected to show a variation of path length The fraction v^2/c^2 is 10^{-8}, so that its presence could probably be tested with excellent precision

ECHO-LOCATION AMONG *COLLOCALIA*

By LORD MEDWAY

Department of Anatomy, University of Birmingham

IT is known that a number of species of the swiftlets (*Collocalia*) of south-east Asia are able to fly in total darkness in the caves in which they nest. When on the wing in the dark or in poor light they utter a series of click-like calls in very rapid succession so that the final effect is a staccato rattle. Novick[1] has recently demonstrated that this call is essential for oriented flight in darkness by *Collocalia brevirostris unicolor*, a swiftlet found in Ceylon.

A similar call is heard from *Collocalia maxima lowi*[2], which nests in a number of caves in Sarawak[3]. In 1957, recordings of this swiftlet were made for the Sarawak Museum with the assistance of staff of Radio Sarawak. Successful recordings were made both under natural conditions in Meraja cave, Bau[4], known to be inhabited only by *C. maxima*, and of individuals of the same species flying singly in the dark-room of the Sarawak Museum, which measures 11 ft. by 16 ft. by 12 ft. high and has interior walls finished in rough plaster and distemper.

The recording apparatus used was a Philips hand microphone type 9564/10 with an E.M.I. portable battery-operated recorder, type *L2B*. Parts of the tape were later played into the 'Sonograph' sound spectrograph to give a plot of frequency spectrum against time. They were also played back into an oscillograph which was photographed on moving film. From these films the spectrum was calculated by carrying out a Fourier transform of the wave-form.

Although blindfolding and deafening experiments were not performed, there are several features of the rattle call of this swiftlet that emphasize its function in dark orientation; many of those listed below are discernible on the tape recording. (Copies of the edited tape, with commentary, are held in Kuching, at Cambridge and by myself.)

(1) Birds approaching the cave from outside are heard rattling while still some distance from the mouth, but those leaving the cave by day in direct flight are silent well within it when in sight of the mouth. This has already been noted and discussed by Novick (*op. cit.*). By night, however, outgoing birds continue to rattle beyond the mouth.

(2) In imperfect darkness the rattle is not continuous but intermittent; clearly its use is not obligatory and, for example, in the dim light near the cave mouth, it is employed only in dark corners where eyesight fails.

(3) In complete darkness the rattle is continuous, although it tends still to be somewhat spasmodic when the bird is on a familiar flight line through a large chamber. The highest rate of steady rattle recorded on the tape is six clicks per sec., but when a bird approaches its nest site, or if it is frightened in the dark, the rate may be higher still.

(4) In dark regions of the cave away from the nest sites, where all birds are in passage to or from the mouth, only the rattle call is heard and never song or other vocalization; apparently the two types of call cannot be uttered simultaneously. This suggests that the mechanism is syringeal; however, the rattle sound is so unlike any other call that a different mechanism may be involved.

(5) Roosting or nesting birds do not utter the rattle call; a bird flushed from the nest is silent for the first yard or two of flight. For this reason attempts to record at the nest sites were unsuccessful.

(6) The rattle call appears late in development, and well-grown fledglings which are forced to fly prematurely often do so silently, and are then totally disorientated in darkness.

In the Museum dark-room, five birds were flown singly. In every case the rattle call was 'switched on' the instant the electric light was switched off; when the light was turned on again it ceased less abruptly, tending to die away slowly into short well-spaced bursts or single clicks. Such brief outbreaks of rattle are heard in the field from swiftlets flying near cliffs or mountain tops, or diving to drink (on the wing) from the rivers. Chasen[5], in an account of weather movements of mixed swift and swiftlet flocks in Malaya, records the rattle call far from any cave.

In caves the rattle is never heard from birds at roost and usually ceases the moment they alight on the nest; but occasional clicks or brief outbreaks of rattle were heard from the caged swiftlets in transit from Meraja cave to the Museum. It seems likely that in unfamiliar surroundings or when close to solid (or liquid) surfaces the rattle call may be used tentatively to supplement eyesight even in full daylight.

Analysis was applied to three recordings: a single bird flying in the cave, a single bird flying in the dark-room, and very many birds rattling simul-

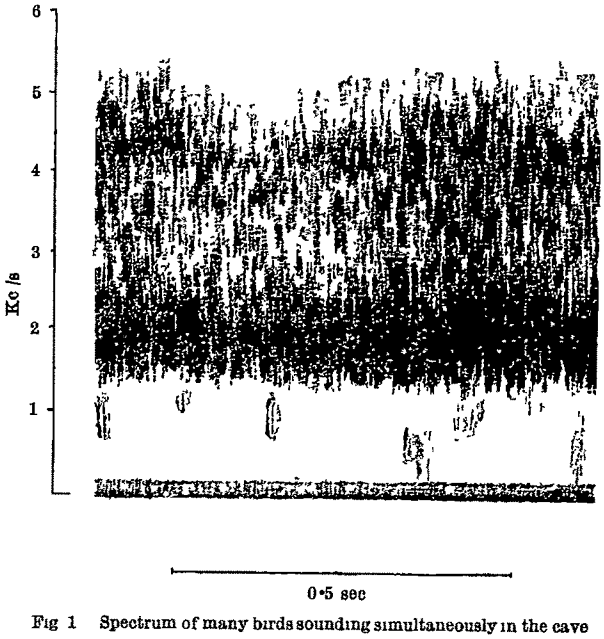

Fig. 1. Spectrum of many birds sounding simultaneously in the cave

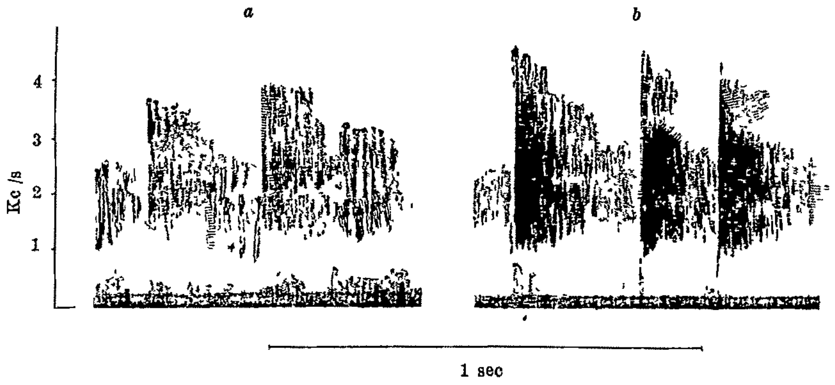

Fig 2, a and b Two different birds recorded separately in the museum dark-room

taneously in the cave mouth by night Results show that the single click is very brief, lasting approximately 2 5 msec The spectrum of the crowd of birds sounding together is continuous from 1 5 to 5 5 kc /s , with peaks at around 2 and 4 5 kc /s (Fig 1) Isolated bursts of sound from individual swiftlets all fall within the same frequency-range (Fig 2), and successive clicks are more or less similar although they show no exact correspondence of wave form The Fourier analyses of the wave-forms correspond well with the sound spectrograms The single clicks of different birds (Fig 2*a* and *b*), however, show different distributions of frequency peaks within the characteristic range , this variation might assist each bird to identify the echo of its own call among a crowd, although in most circumstances the coincidence in timing between emission and echo would be quite sufficient to discriminate against the calls of other birds For example, it can be shown that if the bird neglects all echoes returning more than 10 msec after emission (that is, reflected from more than 5 ft away) it may be able to infer the presence of an obstacle with 90 per cent certainty, even though there may be twenty other birds within a radius of 20 ft This calculation assumes that the echoes from only three successive clicks are noted , if a greater number can be utilized the discrimination increases correspondingly

The only other avian genus known to echo-navigate is the oil-bird, *Steatornis*[6] This utters a similar call , but the mean frequency is considerably higher (7 3 kc /s) and the range (6–10 kc /s) does not overlap with that of *Collocalia maxima*, which is shown to rely for sonic-navigation on lower frequencies than any other bird, bat or dolphin so far investigated Other *Collocalia* in Sarawak also utter the same call , one species (*C esculenta*) lacks it As part of a survey of the life and habits of the genus in Borneo at present in hand, it is hoped soon to extend investigation of the use of echo-navigation and of the physiology of the mechanism involved

I am grateful to Mr Tom Harrisson, curator of the Sarawak Museum, for the opportunity to work in Sarawak, for encouragement in the study of *Collocalia* and for criticism of this communication before publication, to the staff of Radio Sarawak, whose interest and help made these recordings possible , and to Dr K E Machin, of the Department of Zoology, Cambridge, for the analysis of the recordings and for the discussion on the identification of a bird's own call

IONIZATION PHENOMENA IN GASES

THE fourth International Conference on Ionization Phenomena in Gases took place at Uppsala, Sweden, during August 17–21 The very wide programme included sections on plasma physics, as well as on fundamental processes and other applications of electric discharges, and attracted a representative gathering of about 800 scientists from research organizations active in this field in twenty-five different countries This number of delegates represented a considerable increase when compared with the previous Conference at Venice in 1957, and reflects the increasing world interest in this subject After a short opening address by the honorary president, the Rector Magnificus of the University of Uppsala, Prof Torgny Segerstedt, the general pattern of the Conference followed closely that of previous conferences in the series[1], in that part of each day was devoted to plenary sessions, at which general survey papers were read, while for the rest of the time the Conference split into four parallel sessions taking place simultaneously The titles of these sessions were (1) Fundamental Processes , (2) Different Types of Discharges and Their Application , (3) Theoretical and Experimental Studies in Plasma Physics , and (4) Production, Confinement and Heating of Plasmas Since there were, altogether, about 250 papers presented, considerations of space make it impossible to give a complete coverage in this report , instead, a selective review of the papers given in the plenary session together with those in the related sessions which can be regarded as having the most general interest is given, but this inevitably means the omission of mention of many papers

Fundamental Processes

W L Fite (San Diego) presented a paper surveying recent advances in the study of collision processes in gases, in which he first discussed the results obtained for the cross-section for scattering and electron exchange using modulated crossed-beam techniques, work with which he himself has been associated for a number of years Further work on the determination of inelastic collision cross-sections using the trapped electron method was then discussed, and the paper concluded with a review of recent results on heavy-particle collisions using an extension of the modulated cross-beam techniques This particular aspect of the work was discussed in more detail by the same author in a later paper given in Section 1, results being given for cross-sections of charge transfer and ionization for H^+ and H_2^+, and for charge transfer and electron stripping for H^- in H within a range of ion energies from 50 eV to 50 keV Other experiments using crossed beams were described by R L F Boyd and A Boksenberg (London), who reported on measurements of ionization cross-section of electrons in H together with a trochoidal mass spectrometer analysis of the ions produced The trapped electron method was also described in detail in a later paper by G J Schulz (Pittsburgh), who showed that using this method it is possible to study the shape of an excitation function from its onset to 3 eV above onset An interesting result obtained in these experiments was that there is a large inelastic peak in nitrogen and carbon monoxide at 2 3 eV and 1 7 eV respectively , the formation and subsequent decay of temporary negative-ion states of nitrogen and carbon monoxide was put forward in explanation of these results

Several papers were presented on the measurements and calculation of collision cross-sections for particles of high energies up to 200 keV Particularly active in this field are the members of the Physico Technical Institute of the Academy of Science of the U S S R , who presented three papers (two of which were read by N V Fedorenko and the other by V M Dukelsky), giving the results of measurement on electron-capture by multiply charged ions, on the ionization of inert gases by protons, and on the ionization of high-velocity alkali atoms by collisions with atoms of inert gases The results of recent measurements on the growth of pre-breakdown ionization currents for several organic vapours were reported by A E D Heylen (London), and for air by A N Prasad and J D Craggs (Liverpool) and by J Dutton, F Llewellyn-Jones and R W Palmer (Swansea) , in the latter two papers the influence of attachment on the growth of ionization was also assessed A technique for the measurement of attachment coefficients for very low-energy (nearly thermal) electrons in oxygen and nitrogen was described by M A Biondi (Pittsburgh) and the results analysed in terms of two- and three-body collisions Other papers concerned with ionization coefficients were those of J M Meek (Liverpool), who put forward the proposal that the decrease in secondary ionization with increasing concentration of water vapour in air is due to a reduction of the photo-electric emission consequent on the absorption of photons by the water vapour, and of D E Davies, J G C Milne and J Myatt (Keele), who discussed the influence of gas purity, tube geometry and method of calculation on the determination of ionization coefficients in hydrogen and the inert gases

Another survey paper dealing with fundamental processes was given at one of the plenary sessions by G L Weissler (Los Angeles), who described the techniques used to study the interaction of the vacuum ultra-violet photons ($h\nu = 7$ to 30 eV) with gases Of particular interest were the results obtained using mass spectrometer techniques for identification of the ions in the determination of specific photo-ionization cross-sections, and of ion molecular reaction rates for such complex ions as N_2H^+ It was shown that with equal concentration of nitrogen and hydrogen the number of N_2H^+ ions produced per unit light intensity increased with increasing energy of the irradiating photons throughout the range investigated, whereas the number of H_2^+ ions showed a peak within this range Further studies of the interaction of photons with gases were described in papers by D K Davies and F Llewellyn-Jones (Swansea), who discussed the influence of collisions of the second kind between excited and neutral molecules, on secondary ionization in hydrogen, and by A Przybylski (Hamburg), who reported measurements of the absorption coefficients in oxygen and nitrogen of gas-ionizing radiation produced by corona discharges in the same gases The complex structure of the optical excitation functions revealed in experiments with mercury and helium were described by H M Jongerius (Utrecht) in a joint paper with C Smit and J A Smit, and theoretical calculation of the 1*s*–2*p* electron excitation cross-section of atomic hydrogen was reported by A Kingston, B L Moiseiwitsch and B Skinner (Belfast)

Another topic surveyed in a paper at one of the plenary sessions was that of recent work on the study of current growth and on avalanches of large amplification, by H Raether (Hamburg) The techniques developed at Hamburg for the study of single electron avalanches in gases such as methane (where large amplifications can occur during the first electron transit time) were described It was reported that the probability of these large avalanches leading to *kanal* breakdown increased with the number of carriers (electrons) in the avalanche The statistical nature of such avalanches was discussed, and in a later paper H Schlumbohm (Hamburg) described in detail the way in which the primary ionization coefficient may be obtained from measurements of avalanche statistics, and gave results for various organic vapours Another member of the same group, L Frommhold, presented results of measurement of the drift velocity and mean energy of agitation of electrons, obtained by studying the electron component of electron avalanches Raether concluded his paper by discussing the growth of ionization in the case where there is a relatively strong external illumination of the cathode, which makes statistical variations of avalanche size relatively unimportant Experimental results for temporal growth of ionization under these conditions were given by F Llewellyn-Jones and E Jones (Swansea), who showed the importance of the stability of the cathode surface in such investigations which involve accurate measurements of formative time lags, and how the magnitude of the individual secondary ionization coefficients in hydrogen and hence the growth times depend on the state of the cathode surface Another paper on the effect of the state of the cathode on growth times and sparking potentials in hydrogen was given by B J Hopkins (Keele) in a paper with D E Davies, R K Fitch and C F Gozna Breakdown potential measurements for the interesting region below the Paschen minimum and for a c fields were described and discussed by H Niesters and L Graf (Aachen), respectively The way in which space charge influences the current growth to give the observed voltage-current density characteristics was investigated in a paper by A L Ward and M J Reddan (Washington)

The remaining papers under this heading were mainly devoted to problems associated with the bombardment of surfaces by ions and with the consequent sputtering

Arc, Spark and Glow Discharges

Discussing recent progress in arc research in a paper to one of the plenary sessions, W Lochte-Holtgreven (Kiel) first described results of mass spectrographic analyses of heavy ions (produced, for example, from pumping oil) in electro-magnetically compressed arcs, showing that a resolution of 1 part in 4,000 is attainable

The way in which radiation from arc discharges has been analysed to determine the contribution due to the formation of negative ions was outlined, and it was shown that this process contributed in very large measure to the total radiation in oxygen Similar studies in nitrogen have demonstrated the existence of a metastable negative ion of nitrogen with a short life-time of about 10^{-6} to 10^{-7} sec , which is consequently not detectable by the usual mass spectroscopic techniques , this result is in agreement with the results of Schulz mentioned above

Also discussed were chemical processes occurring in arc discharges, and the use of arc discharges in the separation of isotopes of neon, and of neon and nitrogen by thermal diffusion techniques

Experimental and theoretical studies on the decay of interrupted arcs were discussed in papers by H Edels and by D Whittaker (Liverpool), respectively It was shown experimentally that the initial decay of gas temperature during the first 500 μsec is of the order of 1 7° K per μsec from an initial value of 7,200° K , the full recovery taking approximately 1 sec The theoretical treatment proceeded by first determining the steady-state radial distribution for a specified current and field strength and then calculating changes in that distribution as a function of time, using the variation of thermal conductivity, specific heat and gas density with temperature A paper on the re-ignition of a c arcs was given by W Rieder and H Schneider (Vienna), who discussed the measurement, by calorimetric means, of the cooling effect of the electrodes , and put forward an explanation for the sudden step in the re-ignition voltage in the recovery curves for low-current arcs, in terms of the disappearance of electrons from the gap The post-arc behaviour of two practical circuit breakers was discussed in a paper by V K Bisht, G A W Rutgers and D Th J ter Horst (Arnhem) in which measurements on the effect of pressure and rate of rise of re-striking voltage on the value of the post-arc current were reported

The behaviour of argon arcs in axial magnetic fields was discussed in a paper by M. McChesney, P C McNeill and J J Matthews (Rugby), who gave an account of spectroscopic, rotating mirror and voltage-current measurements Arcs in transverse magnetic fields were the subject of a paper by P E Secker (London), who reported investigations of the effect of the cathode surface on arcs moving in the Amperian direction ; experiments on the Amperian and retrograde motion of arcs in a magnetic field inclined to the plane of the cathode were reported in a paper by A E Robson (Harwell)

Sparks in long gaps were discussed in two papers by R T Waters and R E Jones, members of the Associated Electrical Industries, Aldermaston The first paper described how the impulse breakdown of long inhomogeneous field gaps was studied by means of time lag measurements, and how attempts to explain these measurements were made by correlation with field distortion produced by space charge created in the gap by the initial corona bursts In the second paper a different technique for studying the same problems was described This technique involved pulse chopping and high-speed photography to measure the growth times of leader channels to within ± 0 05 μsec The step-lengths of the spark leaders so measured were discussed in relation to the Schonland theory of lightning stepping An analysis of the relation between lightning discharges and whistlers was given in a paper by H Norinder (Uppsala)

Striations in the positive column of glow discharges were discussed in papers by M Klerk (Eindhoven), who described measurement on d c and high-frequency discharges in tubes of various geometries, by W Schallreuter (Greifswald), who investigated the dependence of frequency, wave-length and velocity of moving striations on various discharge parameters, and by A Rutscher of the same laboratory, who described investigations of spectral emission from moving striations in neon glow discharges A theoretical discussion of the positive column of low-pressure mercury-rare gas discharges, using the cross-section curves for excitation and ionization of mercury, the Ramsauer cross-section curves of the rare gases and taking into account the imprisonment of the resonance radiation was given by M A Cayless (Rugby) D Muller-Hillebrand (Uppsala) described investigations of the conditions under which hydrogen–air and propane–air mixtures can be ignited by corona discharges, and concluded that discharges from points with currents up to 100 μamp do not ignite gas–air mixtures, whereas discharges from rounded objects can ignite at an effective current of less than 5 μamp A paper by J S T Looms (Leatherhead) described investigations to assess the importance of corona as a source of interference with micro-wave communication It was found that even when d c powers as great as 60 watts were developed in discharge systems 15 cm in length, no noise output greater than 1 per cent of that of an argon noise reference source was observed From this and other results it was concluded that d c corona is not a serious source of interference in the X-band

Many of the remaining papers in this section were concerned with the mechanism of Geiger-counter discharges, a subject which still provokes attention

Plasma Physics

In reviewing that section of the Conference devoted to plasma physics, main attention must be directed to the plenary session on recent results from research on controlled thermonuclear reactions

The session opened with a series of papers from the United States , J L Tuck (Los Alamos) first discussed recent work on *Scylla* and stated that it was believed that neutrons obtained from this device were truly thermonuclear He also discussed the difficulties inherent in research on controlled thermonuclear reactions due to the onset of cyclotron resonance, and described a new machine, known as *Picket Fence*, having a four-cusped magnetic field configuration, which, it was hoped, would succeed in overcoming the problems created by cyclotron resonance Other work on *Scylla* and on a rotating plasma containment device called *Ixion* had earlier been presented by F L Ribe (Los Alamos), in which measurements of the diamagnetism of the plasma during its acceleration and after removal of the radial electric field were discussed.

R. F. Post (Livermore) reviewed recent progress on mirror machines where investigations have been concerned primarily with (*a*) studies of injection methods, (*b*) investigation of diffusion and non-adiabatic loss processes, and (*c*) further attempts to analyse the energy spectrum of trapped and heated plasma particles. The experimental difficulties being encountered at this stage in the project were outlined. Results were given of measurements of the radial distribution and rate of diffusion loss of the high-energy electron component of a heated plasma, produced by magnetic compression.

The present state of the *DCX* experiment was reported by A. H. Snell (Oak Ridge) and difficulties being encountered in providing a suitably energetic injection system were analysed. The paper discussed, among other things, observations on the spreading of the trapped ions, life-times of trapped particles, the density of the trapped plasma and an assessment of the factors that may be limiting this density. Another, earlier paper by J. S. Luce (Oak Ridge) had discussed in more detail the trapping of high-energy ions within the walls of a hollow vacuum arc. This wall prevents neutral atoms from reaching the trapped ions and therefore reduces charge exchange losses. New arc techniques were described which include plans for 15 in. diameter discharges.

Contributions from the United Kingdom were presented by G. Francis (Harwell), G. B. F. Niblett (Atomic Weapons Research Establishment, Aldermaston) and D. R. Chick (Associated Electrical Industries, Aldermaston). Progress reported from Harwell included the recent identification of Alfvén waves in a high-current toroidal discharge; an earlier paper by D. F. Jephcott (Harwell) had discussed measurements of the velocity and damping of these waves. Other fields of investigation have included experiments with linear pinch and inverse pinch systems (which have shown that in the inverse pinch case the current sheath remains stable for a longer time than in the straightforward pinch system) and some further work on *Zeta*.

Much of the work on devices such as the thetatron (azimuthal current) carried out at the Atomic Weapons Research Establishment, Aldermaston, had been reported in other papers, so that the review by G. B. F. Niblett was confined to a discussion of attempts to produce very large rates of current growth, by the design of very low inductance systems, and some very recent studies of dissociation phenomena in the hydrogen molecule. Rates of current rise of 6×10^{12} amp./sec., with peak currents of 3×10^{6} amp., were reported for the parallel spark gap condenser bank known as *Maggie*. Again, because of many earlier papers from other members of the A.E.I. team, the review by D. R. Chick was confined to a description of the design and engineering of the machine to be known as *Sceptre IV*, and an outline of the proposed experimental programme.

Although members of the U.S.S.R. delegation delivered papers during this plenary session, there were no review papers in the sense of those presented by the United States and the United Kingdom. Because of this, the papers from the U.S.S.R. will be discussed in those sections of this report to which they were directly related. Two other papers concerned with thermonuclear investigations were presented in plenary sessions. W. B. Thompson (Harwell) considered fine-scale magneto-hydrodynamic behaviour in plasmas, where the effects of the finite ion Larmor radius may be important, by use of the collision-free Boltzmann equation. A consistent series expansion of this equation was used to derive first-order magneto-hydrodynamics, and the magneto-hydrodynamic shock was studied as an application of this technique. "Recent Progress in Shock Wave Research" was the title of a paper by A. C. Kolb (Washington), and in it he described the spectroscopic study of temperature and density in shock-wave fronts. Very high-ionization densities had been achieved and there was strong evidence for high temperatures, and thus considerable ionization, ahead of the travelling wave-front, probably produced by a radiation process. In the general paper sessions, those concerned with plasma physics were divided into two: (*a*) theoretical and experimental studies in plasma physics, and (*b*) production, confinement and heating of plasmas. These two sections will be briefly reviewed individually.

Theoretical and Experimental Studies in Plasma Physics

The topics in this section were transport phenomena, interactions involving electric and magnetic fields, micro-wave radiation measurements and spectra from plasmas.

An interesting theoretical approach to transport phenomena was described in a paper by M. N. Rosenbluth and N. Rostoker (San Diego), where, in a fully ionized plasma, all field particles are considered to be in equilibrium except for one 'test' particle. The resultant reaction on this test particle, due to its interaction with the field particles, consists of a frictional drag and a random force that produces acceleration and diffusion in velocity space. A systematic procedure for determining these effects with no magnetic field and in the presence of a constant magnetic field has been developed.

The topic "Interaction involving Electric and Magnetic Fields" produced the largest number of papers of any at the Conference. Among them was a paper by Dermikhanov, Gevarkov and Popov (Moscow) on "The Interaction of a Beam of Charged Particles with a Plasma". This paper described the investigation of plasma oscillations created by a continuously injected electron beam. It was shown that the maximum intensity of plasma oscillation is produced when the electron beam passes through the plasma. Electromagnetic fields with the same plasma frequencies were also found outside the plasma column; the intensity of these oscillations as a function of the density of the plasma was investigated and found to be the same as that inside the plasma column. Detection of these oscillations was possible because of the considerably increased sensitivity of the recording apparatus compared with that used by previous workers. Another paper on this topic was that by Khazchenko and others (Moscow); in this case an electron beam was modulated by oscillations in a plasma through which it passed and afterwards detected in a resonant cavity.

Other papers of interest included one by J. A. Wesson (Associated Electrical Industries, Aldermaston) on the effect of runaway electrons on the heating of a plasma, where it was shown that, for constant electric field, runaway electrons set a limit to the temperature which can be efficiently achieved by ohmic heating, but for constant current density, if the fraction of the current carried by the runaways is small, this fraction will decrease as the temperature increases A paper by I B Bernstein and I N Rabinowitz (Princeton) considered the velocity distribution of plasma electrons in an external magnetic field when the ions are assumed to be infinitely massive, and electron–electron interaction is suppressed These assumptions produced equations which could be solved numerically on a computer, and results indicated that, with an initially Maxwellian distribution, the distribution functions do not develop the double-humped character which oscillation theory indicates to be unstable

J E Allen and F Magistrelli (Rome) described experiments on the plasma sheath transition in the presence of a magnetic field Using an azimuthal magnetic field which could be applied in the 'pinch' or 'anti-pinch' direction, they showed that a magnetic field in the pinch direction reduced the directed energy of the positive ions leaving the plasma and a magnetic field in the anti-pinch direction increased this energy The result was shown to be in accord with theoretical predictions

S C Brown (Massachusetts) in his review paper on "High Frequency Waves in Ionized Gases" considered the various types of electromagnetic waves that are set up in an ionized gas due to the application of a magnetic field There are six natural frequencies, three being cyclotron frequencies and three plasma frequencies Because the magnetic field is a vector the resultant oscillations in the plasma can be parallel or perpendicular to the field and thus a very large range of possible oscillations exists The paper discussed some basic properties of these waves

A fascinating combination of plasma and microwave physics was presented in a paper by G S Kino and B Ludovici (Stanford) The paper discussed a plasma parametric amplifier based on the principle that if electromagnetic waves of three frequencies ω, ω_1 and ω_2 such that $\omega = \omega_1 + \omega_2$ can be propagated through a loss-less non-linear medium with propagation constants β, β_1, β_2, strong interactions will take place between these signals if $\beta \approx \beta_1 + \beta_2$, if ω is of large amplitude there will be a power transfer to ω_1 and ω_2 This principle has been confirmed in a mercury vapour d c discharge with $\omega = 800$ Mc /s, $\omega_1 = 500$ Mc /s, and $\omega_2 = 300$ Mc /s Both ω_1 and ω_2 have been observed to increase in amplitude by a few db in travelling from one end of the positive column to the other

The broadening of spectral lines by Stark effects was discussed by H Margenau (Yale) Equations for the calculation of half-widths were given for three different cases (i) when both electrons and ions can be treated by impact theory, (ii) when the electrons can be treated by impact theory but the ions have to be considered statistically, and (iii) when both electrons and ions can be treated statistically Physical conditions to which these equations are applicable were discussed Improved methods of calculating Stark broadening of spectral lines were presented in a paper by H R Griem (Maryland) and A C Kolb (Washington) It was shown that the calculated line profiles depend only slightly on temperature and can therefore be used to deduce electron densities in dense plasmas from measured profiles with much improved accuracy

Production, Confinement and Heating of Plasmas

This section, as with the other sections of the Conference, was split into sub-sections which were: (a) the longitudinal pinch, (b) mirror machines and the azimuthal pinch; (c) shock waves, and (d) further methods of production and confinement

In a paper by D W Allan (London), consideration was given to the detailed behaviour of the simple unstabilized pinch in respect of the inward movement of the current sheet He concluded that evidence favours the free-particle piston model and the shock-wave model rather than the snow-plough model Whether the behaviour follows more closely the free-particle model or the shock-wave model depends on the effective mean free path

Two papers by S A Colgate, H P Furth and others (Livermore) discussed the linear and toroidal hard-core or inverse pinch Small-scale instabilities in the linear case have been shown to be of non-hydromagnetic origin A toroidal version of the hard-core pinch has been attempted using a magnetic field to levitate a ring conductor inside a toroidal shell This device will be used to study the nature of these small-scale instabilities and also to study the stability of near-vacuum field hard-core configurations and to determine if this stability leads to an improved containment of the plasma energy "A Dynamically Stable Current Column" was the title of a paper by V S Komelkov and others (Moscow) The formation and development of a current cord appearing during the movement of a plasma jet were examined by means of advanced high-speed photographic techniques Measurements were made of the current distribution in the moving plasma jet and showed that the current in the cord had remained stable throughout the half-period of the discharge The existence of a radiation continuum the appearance of which coincided with the appearance of the current cord had also been demonstrated

A Kantrowitz and others presented a paper on the use of collision-free shocks to study dissipation mechanisms in collision-free plasmas At high temperatures, collisional dissipation in plasmas is slow, and losses due to magneto-hydrodynamic turbulence become important Preliminary experiments show that it is possible to produce shock waves that obey the required theoretical condition that the shock thickness is less than the mean free path, and that observations on these thin shocks can provide a powerful tool for the study of dissipative mechanisms in collision-free plasmas

Finally, L Hogberg, K Siegbahn and K Bockasten (Uppsala) described an apparatus for the electrodeless generation and acceleration of plasma rings A single-turn primary winding placed close to the end wall of a 'Pyrex' tube induces a ring discharge which is accelerated as a function of the gas current and the magnetic field Ion velocities in the range 10^6–10^7 cm /sec have been observed with this technique

Conclusion

During the Conference, visits to the Institute of Physics and the Institute of High Tension Research at Uppsala and the Nobel Institute of Physics in Stockholm were organized, a full social programme for members and their wives was also arranged All those concerned with the organization of the conference and particularly the hard-working secretary, Dr Åke Nilsson, of the Institute of Physics, Uppsala, are to be congratulated on the excellence of the arrangements which enabled such a large conference to run so smoothly thoughout

It is no reflexion on this organization to comment that these conferences, including as they do such a wide range of topics, are becoming too large and unwieldy , one possible solution would seem to be to divide the subject-matter into two groups, one devoted to ionization phenomena and gas discharges and the other to controlled thermonuclear research and plasmas If these groups were arranged to run consecutively it would give those with interest in both fields an opportunity to attend more of the lectures in which they are interested, while considerably reducing the total number of delegates present at any given time

The next conference in this series is to be held in Germany, probably at Baden-Baden, during 1961

RADIO ECHO OBSERVATIONS OF VENUS

By J. V EVANS and G N. TAYLOR
Jodrell Bank Experimental Station, University of Manchester

DURING September 1959 an attempt was made to observe radio echoes from the planet Venus using the 250-ft radio telescope at Jodrell Bank The radar equipment used with the telescope operated on a frequency of 408 00 Mc /s The transmitted power was 50 kW , pulse-length 30 msec and pulse repetition rate 1 per sec The receiver had a noise figure of 4 6 db and a bandwidth of 60 c p s The overall losses in the feeders amounted to 2 5 db , and the polarization of the transmitted wave was right circular Observations were made with the telescope in continuous motion to follow the planet across the sky, with alternate periods of transmitting and receiving The length of these periods was approximately equal to the time of travel of the radio pulse to and from the planet (5–6½ min)

No echoes were observed with this equipment stronger than the noise-level in the receiver An analysis of the signals for echoes which were weaker than the noise was made with an integrating equipment, which added together receiver noise powers corresponding to the same range-intervals on successive sweeps of the time-base With this system eight adjacent range-intervals were examined These were made equal in width to the transmitter pulse (30 msec) and their distance along the time-base was controlled in order to compensate for the change in range of Venus, so that any echo would remain in the same 30 msec time-interval It was also necessary to provide compensation for the Doppler shift of the echo relative to the transmitter frequency

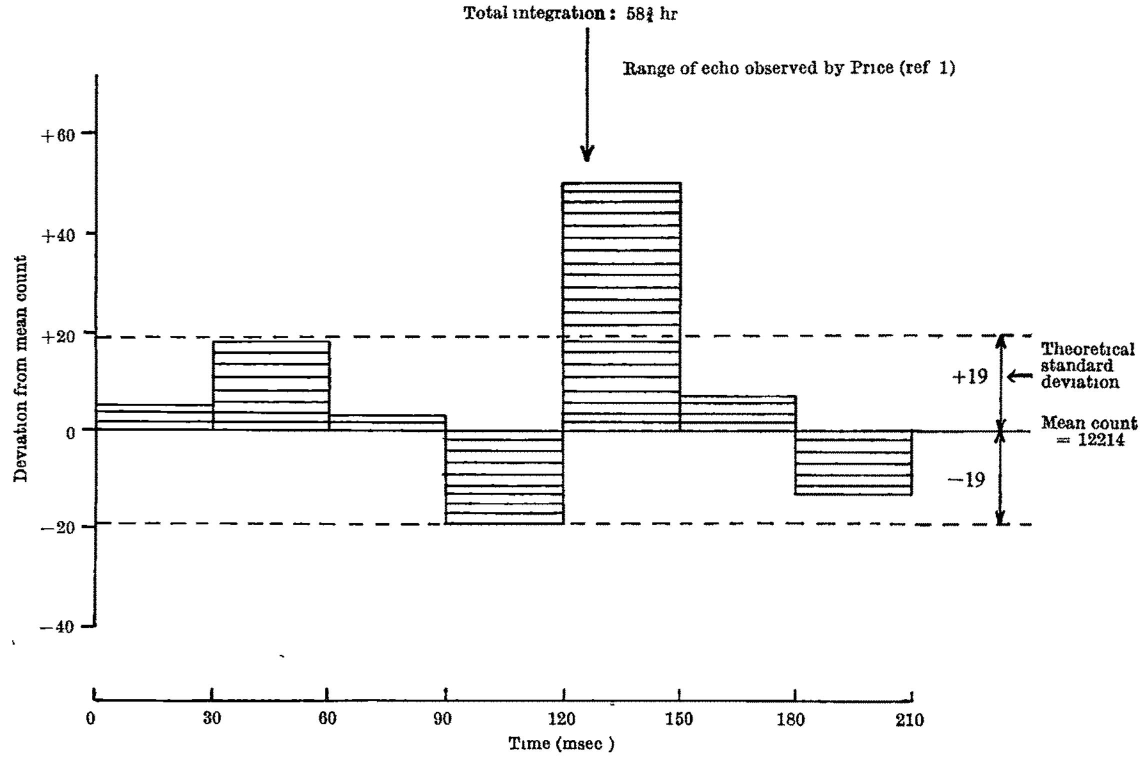

Fig. 1 The deviations of the counters in the integrator system from their mean is plotted as a histogram Different positions of the eight gates along the time base were employed and only seven range-intervals were common to all the periods of observation Hence there are only seven counts shown in the histogram

Exhaustive checks were made to confirm that the integrated noise counts in the eight range channels showed statistical fluctuations which agreed with theory, and that no systematic errors were introduced by, for example, the operation of the transmitter or the telescope Such systematic errors were unlikely because the transmitter and receiver operated alternately for 5–6 min intervals

A total of 58¾ hr useful operating time was obtained before the range of Venus had increased to a point where further work was not considered worth while The addition of all the periods of observation is presented as a histogram (Fig 1) where one of the eight range-intervals shows an excess count of 2½ times the standard deviation The addition of many samples of noise by the integrating equipment gives a Gaussian distribution of counts, hence there is an 8 per cent chance that noise alone will produce a count 2½ standard deviations greater than the mean in one of eight channels If the high count is caused by the planetary echo, then the range observed gives a value for the solar parallax of 8 8020 ± 0 0005 sec of arc This value is in agreement with that obtained by Price *et al* [1] using the Millstone Hill Radar Station operated by Lincoln Laboratory of the Massachusetts Institute of Technology (8 8022 ± 0 0001 sec of arc) The likelihood that, by coincidence, a high count should appear in the range interval predicted by the Millstone Hill result is 1 per cent

The signal-to-noise ratio required to produce an excess count of 2½ standard deviations has been estimated by applying to the receiver signals which are weaker than the noise by a known amount, and is −23 ± 2 db This is within 6 ± 2 db of that expected on the basis of a model for Venus in which it was assumed that the scattering is similar to that observed for the Moon[2] and that the period of rotation is of the order of 20 days However, the result is not in agreement with the work reported by Price, which suggested that the radar cross-section of Venus was equal to the physical area presented by its disk If this were the case a signal-to-noise ratio of about −5 db should have been observed This discrepancy of 18 db in signal strength might be accounted for in two ways (*a*) if the rotation period of Venus is much faster than once every 20 days the Doppler broadening of the echo will cause some of the received power to fall outside the 60 c p s bandwidth limit of the receiver , (*b*) if the echo is subject to large rapid changes in intensity then because a square law detection system was employed at Millstone Hill, a false estimate of the average signal-to-noise ratio would be obtained Such fading could not have been caused by Faraday rotation in the Earth's ionosphere because circularly polarized radio waves were used in both experiments

We are indebted to our colleagues at Millstone Hill for their interest and co-operation, particularly in producing for us predictions of the range and Doppler corrections which were applied to select the received signal

OBITUARIES

Prof. M Caffrey

THROUGH the death of Prof M Caffrey, which occurred on September 17 at the age of seventy, Ireland has lost an outstanding personality in the field of agricultural science and one who took an active part in the Faculty of Agriculture in the National University of Ireland

Michael Caffrey was born at Lughill, near Monasterevan, Co Kildare He received his early education at the local national school and at the Christian Brothers' School, Monasterevan He entered the Albert Agricultural College, Glasnevin, in 1908, and in the following year was awarded an agricultural scholarship into the Royal College of Science, Dublin After a distinguished undergraduate course, he gained the diploma of the latter institution in 1912, and was appointed as assistant to Dr H Hunter in the Plant Breeding Section of the Department of Agriculture, Dublin The studies and work he then undertook under the able guidance of Dr Hunter formed the basis of his later successful career in plant breeding, lecturing and teaching When Dr Hunter resigned after the First World War, Caffrey became head of the Plant Breeding Section of the Department of Agriculture, and when a Faculty of Agriculture was established in the National University of Ireland in 1927, the University made him lecturer in plant breeding, and afterwards in 1938 appointed him to fill the newly established chair of plant breeding, a post which he occupied until his death

Throughout his career, Prof Caffrey remained in close contact with the Department of Agriculture, which he kept supplied with nucleus stocks of leading cereals and grasses These in turn became available to the various county committees of agriculture, by which they were tested and reported on in due course Prof Caffrey was also in close contact with plant breeding stations abroad, and he introduced many foreign cultivars of wheat, oats and barley They were tested against cultivars commonly grown in Ireland and numerous crosses made with the most promising sorts During four decades he produced not only varieties of wheat suitable to local soil and climatic conditions, but also improved varieties of oats and grasses In crossing and breeding, Prof Caffrey was particularly interested in the reaction of the hybrids to disease resistance, and one outstanding case of his work on this aspect may be quoted here At Glasnevin, year after year, the most common and serious disease of wheat has been yellow rust (*Puccinia glumarum*) To combat this, Caffrey produced the cultivar Glasnevin Rosa, a wheat which was immune to yellow rust for seven years, a period which is about usual for varieties bred immune or resistant to rust diseases before they become attacked by new strains of the pathogen which develop in the meantime

Close co-operation always existed between the Plant Breeding Division and the Plant Pathological Division at Glasnevin , and down the years the latter Division has been indebted to Prof Caffrey on many occasions for directing attention to outbreaks of disease and to the appearance of new pathogens on cereal crops

Although Prof Caffrey's entire professional career was devoted to plant breeding, he had a wide interest in all agricultural subjects He was a founder Council member of the Irish Grassland Association, a member of the Agricultural Commission appointed by the Government to examine agricultural development in the late 'thirties, and in general he identified himself with many agricultural developments. He was equally at home with students and scientific audiences, and as a lecturer on behalf of the Royal Dublin Society he became intimately acquainted with and highly appreciated by a wide range of farmers all over the country.

Prof. Caffrey's outspoken manner, genial personality and hearty laugh will long be remembered by all who knew him. He was predeceased by his wife some years ago, and he is survived by three sons and three daughters, for whom the greatest sympathy is felt. R. McKay

Dr. E. J. Holmyard

Eric John Holmyard was born on July 11, 1891, at Midsomer Norton, Somerset, and all his life he was a faithful man of Somerset. He was a scholar of Sidney Sussex College, Cambridge, and after graduation he served as a sixth-form science master at Marlborough College during 1917–19. He then became head of the Science Department at Clifton College, an appointment which he filled with signal success for the twenty years 1920–40. It was at Clifton that his best work was done. In 1941 he became editor of *Endeavour*, retiring in 1954 to live at Clevedon, Somerset. Among his other activities, he was chairman of the Society for the Study of Alchemy and Early Chemistry and co-editor of a "History of Technology" in five volumes.

Holmyard, as a teacher, well knew the capacities of young pupils at school, and his books on inorganic and organic chemistry of this standard have deservedly been very popular. They are written in a lucid and attractive style and many readers of this notice must owe their introduction to chemistry to them. In collaboration with F. A. Philbrick, he wrote a more advanced book on theoretical and inorganic chemistry which has also been very successful. All these books present the basic facts of chemistry as an experimental science, relating them to general principles in a way which gives them significance and interest, but the theory is kept in proper proportion, so that those who gained their knowledge from them in the past will now have very little to unlearn.

Dr. Holmyard, who was a member of the Royal Asiatic Society, will probably be best remembered for his profound studies of Muslim chemistry. He was well equipped with a knowledge of Arabic, and in this field he was a recognized authority. He made a special study of Jābir ibn Ḥayyān and the writings attributed to him. He published some Arabic texts, brought to light some little-known works of Jābir, and re-interpreted some which had previously been studied. More recent research has shown that the problem of Jābir is very difficult and much remains to be cleared up, but Holmyard's pioneering work has a permanent value. He showed that the theory which dominated alchemy and early chemistry, that metals are composed of mercury and sulphur, was taught by Jābir, who derived it from a statement in the "Meteorology" of Aristotle.

In collaboration with his pupil at Clifton, Mandeville, Holmyard published the Arabic text and a translation of a work known in Latin as by Avicenna and showed that it is, in fact, part of the genuine *Shifā'* of Ibn Sīnā. This text, which denies the transmutability of species and stigmatizes alchemical gold as fraudulent, was a puzzle in the Middle Ages, when it was thought to be part of the "Meteorology" of Aristotle. Holmyard also edited and translated an alchemical text of Abu'l Qāsim al 'Irāqī. In all these studies he made much use of the writings of Jildakī, available only in manuscripts, and established their value as a source of information on Muslim alchemy. The work in this field by Holmyard completely changed the outlook on Muslim chemistry which prevailed when he began.

Holmyard wrote some excellent small books on the history of chemistry, the best known being his "Makers of Chemistry" and his recently published "Alchemy". These are accurate and authoritative, and it is to be regretted that he did not write a general survey of Muslim chemistry which he was so well qualified to undertake.

Holmyard was modest and unassuming, ready to put his knowledge at the disposal of those who asked it, with a cool and critical outlook in scholarship, expressing himself concisely and avoiding polemics. His learning sat lightly upon him, and for all he cared it could remain unknown in circles incapable of understanding it. He was open and friendly and in whatever company he found himself his quiet charm and delicate sense of humour, wholly free from malice, endeared him. He was a member of Clevedon Golf Club. He died at Clevedon on October 13, and among those who valued his knowledge and friendship his death leaves a vacant place which it will be hard to fill. J. R. Partington

NEWS and VIEWS

Royal Society: Award of Royal Medals

H.M. the Queen has been graciously pleased to approve recommendations made by the Council of the Royal Society for the award of the two Royal Medals for the current year as follows: to Prof. R. E. Peierls, professor of mathematical physics in the University of Birmingham, for his distinguished work on the theoretical foundations of high energy and nuclear physics; to Prof. P. B. Medawar, Jodrell professor of zoology and comparative anatomy at University College, University of London, for his distinguished contributions in the field of tissue transplantation immunity and acquired tolerance.

Geological Society of London: Foreign Members

The Geological Society of London has elected to foreign membership the following distinguished geologists: Academician V. V. Belousov, of the Academy of Sciences, Moscow, in recognition of his studies on sedimentation and geotectonics; Prof. J. A. Broggi, of Lima, Peru, for his work in the advancement of geological science in Peru and his contributions to Peruvian geology; Academician D. V. Nalivkin, of the Academy of Sciences, Moscow, in recognition of his contributions to the geology of the Soviet Union and especially of his part in the preparation of the recently published geological map of that country , Academician N S Schatsky, of the Academy of Sciences, Moscow, for his work on tectonics, stratigraphy and economic geology , Dr F Prantl, vice-president of the National Museum, Prague, in recognition of his distinguished researches in palæography, stratigraphy and palæontology , Prof Norman D Newell, of the American Museum of Natural History, New York, for his contributions to invertebrate palæontology and his work on reef deposition

British Broadcasting Corporation Science Unit

A Science Unit has been established by the British Broadcasting Corporation with the object of providing a more extensive coverage of science in sound programmes The senior member of the Unit is Dr Archie Clow, who joined the B B C in 1945 and has produced many science series and individual talks, notably the two weekly series "Science Survey" and "Who Knows ?", in which leading experts deal with all kinds of scientific developments in a non-technical way The Unit is also responsible for "Science Review" and Third Programme science talks and discussions Recently, Mr David Edge joined Dr Clow in the Talks Department Both received their earlier education at Aberdeen, the former at Aberdeen Grammar School and the latter at Robert Gordon's College Mr Edge did research work in radio astronomy for three years after taking his degree in physics at Cambridge in 1955

A third member of the Corporation staff who is contributing to the expansion of science broadcasts is Mr C L Boltz, who is now attached to the News Division as science correspondent (*Nature*, 183, 1231 , 1959) He formerly worked for seven years in a similar capacity in the B B C 's European Service Succeeding Mr Boltz in the European Service is Mr Bryan Silcock, who was born in Liverpool in 1933 and has since 1957 been an assistant editor of *Nature* He went to Dartington Hall School in Devon, and after National Service in the West Yorkshire Regiment and the Royal Artillery, to Jesus College, Cambridge, graduating with honours in natural science

British Commonwealth Education Liaison Committee

In a written answer in the House of Commons on November 12, the Minister of State for Commonwealth Relations, Mr C J M Alport, stated that in accordance with the recommendations of the Commonwealth Education Conference, representatives of all member countries in the Commonwealth met in London on October 27 under the chairmanship of Sir Henry Lintott It was proposed to establish a Commonwealth Education Liaison Committee, comprising one representative of each member country and of Nigeria, and in addition the United Kingdom would appoint a member to represent the other Colonial territories This Committee would follow up and record progress on the schemes of assistance agreed at the Oxford Conference and would also consider suggestions for the further improvement of Commonwealth co-operation in education, and, in particular, it would prepare material for submission to the next Commonwealth Education Conference, to be held in India in the winter of 1961–62, at the invitation of the Government of India The chairman would be Sir Philip Morris, and under the general direction of the Liaison Committee there would be a Commonwealth Education Liaison Unit, consisting initially of a director (who would also be secretary to the Committee) and one administrative assistant The Unit would supplement normal direct dealings between the countries of the Commonwealth on education, and would deal on request with inquiries from education authorities in Commonwealth countries and generally act as a reference centre The cost of the Unit would be shared between member countries of the Commonwealth

United States and Great Britain to exchange Data on Advanced Gas-cooled Reactors

The United States Atomic Energy Commission and the United Kingdom Atomic Energy Authority have signed a five-year agreement to exchange technical information on advanced gas-cooled reactors The exchange, effective as from November 16, will be carried out under the terms of the agreement between the two countries for co-operation in the civil uses of atomic energy, which has been in effect since 1955 Data will be exchanged on development, design, construction and operation, as well as on related research and development, of the advanced gas-cooled reactors being built at Windscale, England, and on the U S experimental reactor project of this type at the Oak Ridge (Tennessee) National Laboratory Information exchanged under this agreement will be made available to British and American industry

British Book Exhibition in Moscow

A large exhibition of British books and periodicals sponsored by the British Council and the Soviet Ministry of Culture is opening in Moscow on November 21 for a fortnight A similar exhibition of Russian books and periodicals will be shown at the Festival Hall in London next February This will be the largest exhibition of British books and periodicals to have been shown in the U S S R at any time, so far as is known Between three and four thousand books will be exhibited together with six hundred periodicals a display of posters and large photographs The exhibition will be shown in the main lecture hall of the Lenin Library, one of the largest libraries in the world The books selected by the British Council have been provided free of charge by British publishers through the co-operation of the Publishers' Association The main emphasis lies on science and technology, although there are important sections dealing with the arts and the humanities Under the terms of the agreement made with the Soviet Ministry of Culture, there are no sections on religion, politics or economics Two-thirds of the periodicals are on medical and scientific subjects At the end of the exhibition all the British material will be handed over to the Soviet Ministry of Culture for use in Russian libraries and cultural institutions

New Zealand Research on Weed Transportation

Weed species are sometimes inadvertently introduced into one country from another, but it is not always possible to establish the means by which this occurs A J Healy, of the Botany Division, Department of Scientific and Industrial Research, Christchurch, has given some particular instances of introduction of foreign species into New Zealand (*New Zealand Journal of Agricultural Research*, 2, No 2 , April 1959) The first example is a straw envelope from a whisky bottle picked up in a rubbish heap on a North Canterbury farm The envelope contained a flowering stem of bindweed, *Calystegia sepium*, portions of an inflorescence of tall oat grass, *Arrhenatherum elatius*, and a bent grass, *Agrostis* sp Such containers when discarded are generally thrown on rubbish heaps and other sites suitable for weed establishment A plate-glass container from an English source, examined in the Wellington district, contained wheaten straw in which was found portions of Californian thistle, *Cirsium arvense*, cleavers, *Galium aparine*, willow weed, *Polygonum*, fruiting material of *Beta* sp , nipplewort, *Lapsana communis*, and a hemp nettle, *Galeopsis* sp This straw was being used locally both for compost heaps and in racing pigeon cages, which would further serve to disperse the weeds throughout the country An examination of the trouser cuffs of a tourist returned from a trip through Spain, France, Switzerland and Italy revealed fruits of Gramineae and Compositae

University News

Birmingham

The title of reader in mathematical physics has been conferred on Dr J G Valatin, senior lecturer in mathematical physics The following appointments have been made to lectureships Dr H B Griffiths (pure mathematics). Dr J K Brown (chemistry), Dr M E Davies (botany), Dr Nancy Montgomery (botany), Brenda Manly (zoology), J Cohen (zoology), C R Sladden (biology in the department of zoology), Dr D J Blundell (geology), I R Smith (electrical engineering), K B Haley (engineering production), Dr V G Jenson (chemical engineering), K A Redish (computing in the Department of Mathematical Physics), N A Dyson (physics), N A J Rogers (chemistry)

The annual lecture of the Institute of Education is to be named "The Raymond Priestley Lecture" in recognition of the help which Sir Raymond Priestley gave to the Institute of Education when the Institute was established

Preliminary plans have been approved for a building for highway and traffic engineering as an addition to the new Civil Engineering Building

Oxford

The following research grants are announced from European Research Associates, Brussels, £1,200 for one year from September 1, for research on acetylene chemistry being carried out in the Dyson Perrins Laboratory under the direction of Prof E R H Jones, from the Department of Scientific and Industrial Research a grant not exceeding £3,400 for the year ending July 31, 1960, for the maintenance of the 140 MeV synchrotron for nuclear physics research in the Clarendon Laboratory, from the Colonial Medical Research Council a grant not exceeding £2,500 for a further two years ending August 31, 1961, for the study of the sensory neurohistological changes in skin infected with leprosy, being carried out in the Department of Human Anatomy under the direction of A G M Weddell, reader in human anatomy, from the Smith, Kline and French Research Institute a grant not exceeding £1,500 for research on the electrophysiology and pharmacology of smooth muscle to be carried out in the Department of Pharmacology by E Bulbring, from the United States Public Health Service a grant not exceeding 30,600 dollars for the year beginning September 1, 1959, for research in the Department of Biochemistry under the direction of Sir Hans Krebs

Announcements

Prof C F Carter, Stanley Jevons professor of political economy and Cobden lecturer in the University of Manchester, has been appointed a member of the Council for Scientific and Industrial Research, in succession to Prof E A G Robinson, who retires on completion of his period of service Prof Carter's interests are in the field of applied economics He is the author of "Industry and Technical Progress" (with Prof R B Williams), published in 1957, and "Investment in Innovation", 1958, he is chairman of the Science and Industry Committee of the Royal Society of Arts, the British Association for the Advancement of Science and the Nuffield Foundation

The Metallurgical Society of the American Institute of Mining, Metallurgical, and Petroleum Engineers, in association with Interscience Publishers, Inc , has announced the publication of a new series of books entitled "Metallurgical Society Conferences", each volume being the proceedings of a technical conference sponsored by the Society through one of its technical committees It is hoped by these means to provide for co-ordinated and comparatively rapid publication of scientific and engineering papers of interest to metallurgists The first volume in the series, "Flat Rolled Products, Rolling and Treatment", can be ordered from Interscience Publishers, Inc , 250 Fifth Avenue, New York 1, New York (price 3 75 dollars)

The Population Council Incorporated of New York is making grants totalling 89,348 dollars over three years to the National Institute for Research in Dairying The award is in support of researches on cervical mucus, with particular reference to the control of fertility, to be carried out in the Physiology Department under the direction of Dr S J Folley

Industrial and Trade Fairs, Ltd , announce that a conference on New Engineering Materials and Design will be held in conjunction with the first Engineering Materials and Design Exhibition at Earls Court, London, during February 22–26, 1960 Among the subjects selected for discussion at the conference will be safety factors and the appearance in design Further information can be obtained from the Secretary for the Conference on Engineering Materials and Design, Drury House, Russell Street Drury Lane, London, W C 2

At the annual general meeting of the Photobiology Group, held at the National Physical Laboratory, Teddington, on November 6, Dr D Vince, of the Department of Horticulture, University of Reading, was elected honorary secretary in succession to Dr E M F Roe

The sixth National Symposium on Reliability and Quality Control in Electronics will be held at the Statler Hilton Hotel, Washington, D C, during January 11–13, 1960 Further information can be obtained from Mr R Brewer, The Research Laboratories, The General Electric Co , Ltd , Wembley, Middlesex

Errata In the communication entitled "Effect of Sorbitol on the Urinary Excretion of some B Vitamins in Man" in *Nature* of September 19, p 911, the numerical values of the ordinates have been inverted , thus, reading from below upwards, the values for riboflavin should be 150, 200, 250 μgm , those for thiamine, 10, 20, 30 μgm , those for N-methylnicotinide, 2, 3 mgm

ASSISTANCE FOR UNDER-DEVELOPED COUNTRIES

THE Queen's speech at the opening of Parliament on October 27 referred to the Government's urgent concern to improve conditions of life in the less-developed countries of the world and its intention to promote economic co-operation and support plans for financial and technical assistance. This was warmly welcomed in both Houses in the subsequent debates. Lord Stoneham asked for further information on this matter and, emphasizing its urgency, stressed the need to seek international agreement to stabilize basic commodity prices, the fall in which in 1958 had cost the under-developed countries 2,000 million dollars. Only urgent and increasing financial and technical assistance can avert the human suffering implicit in the two-thirds increase forecast in the population of Asia in the next fifteen years. The Marquess of Lansdowne was unable to specify the exact increases but assured Lord Stoneham that the Government intended to increase considerably contributions in the various fields of aid to under-developed countries. Lord Home also expressed the view that the foundation of peace probably lies in bringing the standard of living of the under-developed nations nearer to that of the industrial nations. In replying on the debate, the Lord Chancellor said that under the Colonial Development and Welfare Acts, £140 million would be available for the Colonial territories during the next five years, with up to £100 million more by way of Exchequer loans. External private investment of all kinds averaged £90 million a year, two-thirds being from the United Kingdom, and it was estimated that the United Kingdom's financial contribution to the Colonial territories averaged £100 million a year in 1956–58. Economic and technical assistance to all overseas countries and territories from United Kingdom public funds rose by a third in the past financial year to about £100 million, and is expected to increase similarly this year, exclusive of military assistance and certain emergency and miscellaneous expenditure amounting to about £30 million. Subject to agreement on the constitution for the new International Development Association, Parliament would be asked to put £50 million into the new Association.

In the House of Commons, Mr. J. Harvey, referring to the growing awareness of the need to give greater assistance to the under-developed territories, suggested that the Government might take some initiative in stimulating such interest so as to enlist voluntary contributions in addition to Government funds for this purpose. Mr. W. Owen suggested the Co-operative movement as a possible source of experience, knowledge and enterprise in this connexion, and Sir John Barlow advocated use of the International Monetary Fund to stabilize world production and prices of such primary commodities as tin and rubber. Mr. H. A. Price, pointing out that we are already devoting more than 1 per cent of our national expenditure to the under-developed countries, thought that we could do much more and that these territories offer great potentialities for the production of increased wealth. The President of the Board of Trade, Mr. R. Maudling, referred to our need to increase our balance of payments position if we are to play our full part in helping the development of these countries, and Mr. J. Arbuthnot suggested that reduced taxation in these countries would greatly assist in the creation of the conditions for development.

Mr. Anthony Head emphasized the vital importance of giving adequate attention to the backward, dependent and under-developed countries during the next five or ten years. He directed attention more particularly to the educational problem, and urged that here the West needs to overhaul its whole approach, and that co-ordinated effort is imperative. In this he was supported by Mr. K. Zilliacus, who pointed out that economic co-operation and the provision of financial, economic and technical assistance to backward countries internationally through the United Nations represent the support of constructive and modernizing forces. Sir Henry d'Avigdor-Goldsmid and Mr. J. Grimond spoke strongly in the same sense, Mr. Grimond referring also to the importance both of the type of government which is established in the newly independent territories and of education, including technical education. Mr. Philip Noel-Baker was somewhat critical of the magnitude of our present contribution. Although our contribution to United Nations Technical Assistance has risen from 2·5 to 3·0 million dollars, the Commonwealth has every year received far more from Technical Assistance than it has paid in, and against the increase in our contribution to the United Nations Special Fund from 1 to 5 million dollars should be set the schemes, costing 15 million dollars, for work in the Commonwealth already submitted by the Colonial Office to Mr. P. Hoffman. Moreover, the £1,000 million loan to the under-developed countries by the International Bank during the first twelve years of its existence was less than one-tenth of the extra capital required during the following ten years to achieve Mr. Hoffman's objectives.

Replying on the debate, the Minister of State for Foreign Affairs, Mr. J. Profumo, recognized the importance of the struggle for men's minds and the part which the Chancellor of the Duchy of Lancaster has to play in that connexion. He also took up the point about education, which had been stressed separately in the Queen's speech in a reference to the introduction of legislation to implement recommendations of the Commonwealth Education Conference, which had been warmly welcomed by Mr. E. Gardner and, in the House of Lords, by Lord Hastings. Lord Home, noting that the presence of 42,000 overseas students in Great Britain put a considerable strain on our universities and technical colleges, welcomed Lord Hastings's reference to the importance of education; nevertheless he thought that the task of equipping youth to meet the intellectual, physical and moral challenge of the time will strain our resources to the full. Apart from a reference by Mr. P. Wall on November 2 to the way in which the under-developed countries in Asia, Africa and the Middle East are beginning to realize the importance of European capital and European technicians, there was no further reference to the under-developed countries in the debate on the Address, although others besides Mr. Wall stressed the importance of education when the position in Central Africa was discussed at some length on November 2.

NEW RESEARCH LABORATORIES FOR THE CAMBRIDGE INSTRUMENT COMPANY, LTD.

By DR. M. C. MARSH
Head of Research Department

ON October 14 a new block of research laboratories for the Cambridge Instrument Company, Ltd., was opened by Lord Adrian, Master of Trinity College and until recently Vice-Chancellor of the University of Cambridge. Following the opening, about 120 distinguished guests were entertained to lunch by the Directors of the Company, and they afterwards had an opportunity to inspect the new accommodation. On October 16 an open day was arranged for shareholders and for guests from the University and from several research establishments in the neighbourhood of Cambridge. About four hundred guests availed themselves of this opportunity. On both occasions the guests were received by Dr. P. Dunsheath, chairman of the Board of Directors, and Mr. H. C. Pritchard, managing director of the Company.

This new building is the result of a decision to expand greatly the research and development facilities of the Company. It provides about three times the previous floor area and permits the whole of these activities, which before this were dispersed in various parts of the works, to be brought under one roof, together with a design and drawing office.

The new laboratories are situated in Chesterton Road, adjacent to the Cambridge factory. They have a very fine view over the River Cam and over Jesus Green and provide accommodation suited to the work to be undertaken. As will be seen from Fig. 1, the clean, modern appearance of the building is emphasized by large windows that run the length of the first three floors and also by the colour contrast afforded by the light buff brickwork of the side walls and the dark green of the slate panels beneath the front windows. The building, which has a floor area of approximately 20,000 sq. ft., has four storeys and is provided with a three-storied entrance block and a rear link block giving access to the factory buildings. The mode of construction gives a clear area on each floor entirely uninterrupted by columns or beams, and extensive use has been made of modern building materials and fittings, such as red thermoplastic flooring, heating coils embedded in the structure, double-glazed windows and acoustic panels.

The entrance block is distinguished by a spacious entrance hall, which is decorated in contemporary style and contains an instrument showroom and a reception area. The block also houses offices and a lift serving all floors.

The laboratory block consists of four floors approximately 100 ft. long and 40 ft. wide. On the ground floor is the mechanical engineering laboratory with its offices, stores and constant-temperature room. Instrument makers' benches and experimental benches are arranged mainly beneath the front windows, and the remaining floor space is taken up by precision machine tools and mechanical laboratory equipment. The first floor is devoted to physics and electronics. It has a large and airy main laboratory, offices, dark room and optical laboratory, standards room and electronics workshop. The second floor houses the physical chemical laboratory which, in addition to offices, has special rooms for balances, glass-blowing and for chemical preparations. Polythene and 'Vulcathene' fittings are used in a special system for draining chemical waste from this floor. The top floor is taken up by design and drawing offices. Excellent lighting is provided by a number of roof-lights in addition to windows running the entire length of both walls. Along the front of this floor is a covered balcony, edged with flower-boxes.

In designing the laboratories, great stress has been laid on versatility. With this in view all the services are laid in trunks of ample size, and it would be an easy matter to add any facilities not originally provided. Besides the usual supplies of gas, water and electricity, there is a special low-voltage electrical supply for portable apparatus. At 18 places there are boards containing four terminals and an appropriate switch. From a central control board it is possible to feed to these terminals a three-phase and neutral supply of any required voltage, single-phase a.c. of any voltage up to 250 volts at frequencies between 25 and 60 c./s., a.c. stabilized against changes of voltage and frequency and d.c. between 0 and 250 volts. These supplies are obtained from trans-

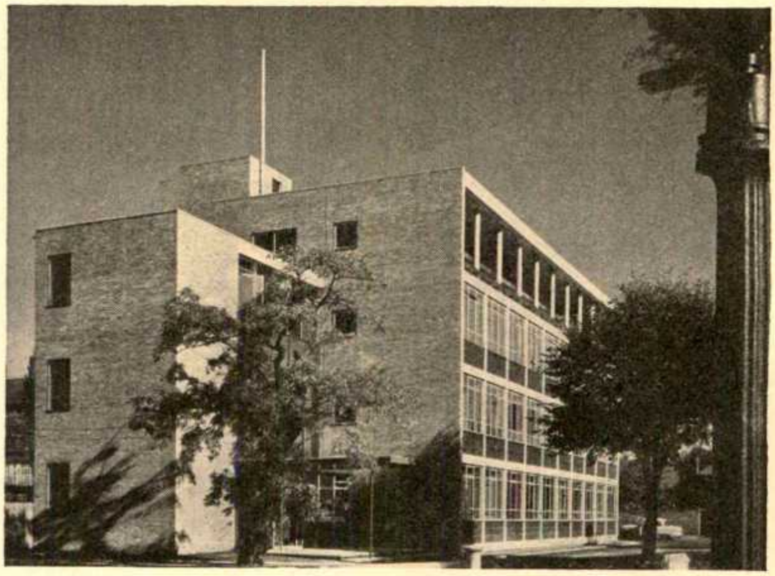

Fig. 1. Research Laboratories of the Cambridge Instrument Company, Ltd.

formers, stabilizer and a Ward Leonard set with a connected motor alternator The last two are situated in a cellar but are controlled from two points in the laboratories On the third floor a large glass de-aerator of special design has been fitted in order to supply oxygen-free water for researches on boiler feed-water problems Compressed air of high and low pressure is supplied to all laboratories, with an extra high-pressure supply in the mechanical laboratory

The building was completed in the remarkably short time of just under one year by Messrs J Jarvis and Sons, Ltd (London and Manchester), to the design of the architects, Messrs Edward D Mills and Partners Light oak furniture with teak tops has been supplied to all the laboratories by Messrs Baird and Tatlock (London), Ltd

These laboratories are now fully occupied and, with an expanding staff, a large programme of research and development work is being undertaken This programme relates to improvements to instruments which are already being manufactured, as well as to a number of entirely new projects in which the Company is interested.

CARBON-DATING CONFERENCE AT GRONINGEN

SEPTEMBER 14–19, 1959

ON the invitation of Prof Hl de Vries (Natuurkundig Laboratorium) and Prof H T Waterbolk (Archaologische-Biologisches Instituut), of the University of Groningen, a small conference of scientists from carbon-dating laboratories was held in Groningen during the week September 14–19 It was similar in character to the conferences held in Copenhagen, Cambridge and Andover, Mass , already reported in *Nature*[1,2] and *Science*[3] Twenty-two dating laboratories were represented, some well established and others just getting into their stride, from twelve countries We were happy for the first time to welcome Russian colleagues at these meetings Some thirty-five communications were made to the meeting, which was partly concerned with the technique of carbon-dating and partly with selected aspects of its application to geological and archæological problems

There was less emphasis than hitherto upon the techniques of counter and circuit design, but nonetheless there was a very interesting survey of the methods in use at various laboratories Two laboratories described their scintillation counting techniques, that at Saclay, using paraldehyde, and that at Trinity College, Dublin, using methanol While a few laboratories use acetylene or methane in their proportional gas-counters, it seems that the majority of dating laboratories now favour carbon dioxide counting Considerable emphasis was laid on the need for careful pre-treatment of samples, especially with difficult materials such as bone, charcoal, cave-earths and all samples of great age Accounts were given of several promising investigations into matters affecting the principles of the method and its applications, as, for example, those at Heidelberg illustrating possible seasonal variations of radiocarbon content of the atmosphere Particular interest was attracted by an account of the joint investigations of Cambridge, Copenhagen and Heidelberg upon possible fluctuations in the initial atmospheric carbon-14 concentration during the past 1,200 years , this is a promising extension of ideas recently suggested by de Vries[4] as possibly offering insight into past climatic changes

Without attempting to summarize all the interesting contributions, it may suffice to point to two or three fields in which the application of carbon-dating has now apparently led to a highly significant advance in knowledge First, we may note a series of datings made at Groningen of the earliest Neolithic cultures from south-eastern and central Europe, indicating a spread from the Near East across these regions as early as 4000 B C , these findings were paralleled to some extent by numerous datings made in Pisa upon Italian material

Several contributions concerned the dating of stages of the last glaciation characterized by stratigraphy, archæology or biological and climatic evidence Here the contribution of Groningen was particularly important, since the technique of isotopic enrichment had permitted the addition of several half-lives to the maximum possible age attainable[5] With favourable materials that warrant this costly and lengthy process, ages as great as 64,000 ± 1,100 years are attainable This in fact appears to be the date of the first mild interstadial period after the last (Eemian) interglacial There is considerable evidence now for an interstadial about 30,000 years ago at several places in western Europe From the American laboratories comes very convincing evidence obtained by dating ocean cores, and deposits both in the Caribbean and in salt lakes, for a very abrupt amelioration of climate about 11,000 years ago It is striking that this climatic break corresponds exactly with the well-dated Late-Glacial period of climatic change in Europe

A substantial part of the time of the meeting was properly devoted to various matters of co-ordination of the work of different laboratories The successful outcome was reported of two policy decisions taken at earlier conferences, namely, to establish an agreed system of publication of date-lists and to publish a punch-card system of all published dates The first of these objectives has been met by the publication of the Radiocarbon Supplement of the *American Journal of Science*, the first volume of which appeared in May of this year The second was met by the formation of Radiocarbon Dates Association, Inc Mr Fred Johnson gave a description of the principles he had adopted in designing the punch-card system and reported the first issue of cards to subscribers It is not yet sufficiently widely known by archæological, geological and biological laboratories concerned with the history of the past 70,000 years how massive is the contribution already made by carbon-dating to knowledge of this period, nor what a very rich source of information this punch-card system will provide. (Inquiries for subscriptions to the carbon-dating punch-card index should be directed to Radiocarbon Dates Association, Inc , Robert S Peabody Foundation for Archæology, Philips Academy, Andover, Massachusetts, U S.A)

With regard to future procedure, it was decided that all carbon-dating laboratories should check by a common standard and that this should be the oxalic acid standard of the U S Bureau of Standards It was agreed that a value of 95 per cent of this standard activity could be taken as the agreed radiocarbon activity for organic material (but not shells) originating in A D 1950 This decision should remove many of the minor difficulties caused by the different laboratories having individual standards of contemporary activity on which to base their calculations of age, and it is hoped that either the next or the next but one date-list of every laboratory will be based upon this agreed standard, which will take care of the industrial carbon and hydrogen-bomb effects upon recent samples. It was at the same time recognized that the carbonate sample provided by Heidelberg would be a further check of importance , that laboratory has undertaken the co-ordination of all inter-laboratory calibration measurements

It was agreed to defer decision on a carbon-13 standard, pending exact absolute determinations to be made in the Lamont Laboratories

It was agreed to use the methods of presentation of bibliography now employed in the Radiocarbon Supplement and in *Quaternaria* the conference also recommended that new dating stations should adopt as their index letters the most distinct and simple combination possible, avoiding those that have already been used even by stations not at present producing dates

While there was no agreement as to whether dates ought preferably to be expressed as B P (before the present), or B C (and A D), there was considerable sympathy for the view that dates primarily relevant to archæology should be given in the B C /A D scale, even where the date B P had also been given

Members of the conference had the concentration of lecture room attendance broken by visits to Prof de Vries's laboratory, to the great peat bog and moraine region south of Groningen and to the dramatic areas of reclamation where carbon-dating is assisting the Geological Survey to provide fundamental knowledge of the stratigraphy of coastal deposits

The thanks of all participants are due to all our Dutch hosts, to the Rektor Magnificus of the University of Groningen, to the Royal Dutch Shell Company, to the Chief Engineer and Director of the Rijks Waterstaat, and above all to the primary organizers of the conference H GODWIN

ENZYMES IN THE FOOD INDUSTRY

THE Committee of the Food Group of the Society of Chemical Industry has an established reputation for organizing symposia on subjects of vital importance and with a wide range of interest to food scientists and technologists The most recent, held on October 1–2, dealing with enzymes associated with the manufacture, storage and distribution of food, attracted an audience which taxed the capacity of the hall of the Royal Society of Medicine in which it was held The organizers very wisely decided to limit the scope of the contributions and to divide them roughly into two groups one dealing with the production of enzymes and their use in manufactured foods and the other with the activity, both useful and deleterious, of naturally occurring enzymes in foods.

Dr Malcolm Dixon opened the symposium with a paper, giving in his own characteristic way the necessary background information on the types of reactions which may be catalysed by enzymes, and such of their properties as would have a bearing on the matters discussed by later speakers The value of such an introduction to a symposium covering a broad field of biochemistry cannot be too highly stressed when it is appreciated that the audience was composed mainly of persons connected with the food manufacturing and processing industries, specialists maybe in rather limited fields, who frequently find it hard to keep abreast of fundamental developments

The remainder of the first day was given over to papers dealing with fungal amylase, invertase, rennin, glucose-oxidase, the pectin-degrading enzymes and proteinases from plants and micro-organisms The main interest in fungal amylase and invertase was in the methods adopted to secure conditions of culture of the selected organism so that high yields of high-purity enzyme are possible on a commercial scale The discussion on the papers not unexpectedly centred around the newer applications of enzymes by the food industry and in particular the use of amylase in bread-making, the application of such proteinases as papain, bromelin (from pineapple) and ficin (from figs) to meat with the view of increasing its tenderness, and the recent availability of glucose oxidase as an oxygen scavenger in packaged foods

The proceedings of the first day having presented the enzymes in a favourable light, as processing aids in a variety of food products, the second day, devoted to "Innate Enzymes Their Action and Control", revealed the reverse side of the medal and showed enzymes in a less co-operative mood This was not unexpected . Dr Dixon, in his introductory remarks, had already pointed out that foods are the product of enzyme action in the living plant or animal and are metabolized after consumption by enzyme action in the body of the consumer, stressing the fact that in the living cell the urge of the enzyme processes is towards synthesis and that enzyme changes in foods, which can be regarded as post-mortem changes, may well be deteriorative in character It is, however, sometimes difficult to draw the line , the enzymic ripening of fruit leads progressively into the deteriorative changes of over-ripening Other cases are more specific papers presented during the day dealt with enzymic deterioration in colour (blackening of potatoes by polyphenolase), in flavour ('soapiness' in coconut and palm kernel oil products due to liberation of free fatty acids by lipase action) and in nutritive value (oxidation of ascorbic acid and of vitamin A precursors in plant tissues)

The problem of control is a formidable one 'Cold storage merely delays but does not prevent enzymic deterioration, since enzyme reactions, like all other chemical reactions, are slowed but not stopped by lowering of temperature Other standard methods, such as the addition of inhibitors or competitive substrates, are by no means universally applicable Probably the most commonly used procedure is that of heat inactivation ('blanching'), but this can lead to unwanted structural changes in fruits and vegetables At present there is no simple and universal solution

It must be said that on one point the arrangement of the symposium was open to critical attack, namely, the lack of time available for free discussion It is in this discussion that the value of a symposium such as this largely resides, both for the audience and for the contributors themselves Arrangements had been made for the discussions to be opened by appropriate authorities and these authorities presented what virtually amounted to additional contributions, comparable in weight and importance to those of the main contributors On this account, the unscripted discussion was seriously restricted, particularly at the final session, and a number of potential questions had to remain unasked and unanswered This was undoubtedly a loss and one can but ask that the point should be borne in mind when future symposia are being planned

It is, however, pleasant to record that the symposium went with a swing to the end and was closed by the clock there was no noticeable whittling away of the audience as special interests were disposed of In its lighter moments the meeting considered future possibilities , these included 'tailored' enzymes for specified purposes and the application of enzymes to the restoration of flavour in over-cooked cabbage It was also pointed out that one speaker had coined a new word—the verb "to enzyme" The purists may refuse to accept this innovation, but we must all accept the importance of the process it describes

BIOCHEMICAL RESEARCH IN INDIA

GOLDEN JUBILEE SYMPOSIUM

A SERIES of symposia was organized by the Department of Biochemistry, Fermentation and Pharmacology Laboratories of the Indian Institute of Science, as part of the celebrations of the golden jubilee of the Institute, during August 28–30, and was attended by more than two hundred scientists including fifty delegates representing important centres of biochemical research in the country The subjects covered were "Biology and Biochemistry of Micro-organisms", "Enzymes" and "Vitamins"

The symposia were inaugurated by Dr S Bhagavantam, the director of the Indian Institute of Science, and the first day of the session was presided over by Major-General S L Bhatia, who spoke on the "Progress of Physiology and Biochemistry in India" Prof P S Sarma, who presided over the proceedings of the second day, outlined the contributions in enzyme chemistry made by the late Prof K. V Giri (see *Nature*, 182, 1201 , 1958) Dr V N Patwardhan, who took the chair on the third and final day of the symposium, gave an address on the mode of action of vitamin D on which he and his group have been working for the past two decades He and his collaborators have adduced experimental evidence to show that vitamin D acts presumably by promoting the synthesis of citric acid in the epiphyseal cartilage Dr. V Subrahmanyan, director of the Central Food Technological Research Institute, Mysore, who was professor of biochemistry in the Indian Institute of Science from 1931 until 1949, reviewed the work done in the department during his regime He gave a brief account of the development of the Bangalore process of composting, the elucidation of the principles of sewage purification, the preparation of a material from paddy husk for defluorinating fluoride-containing waters and the preparation of insulin and other hormones from slaughter-house material and vegetable 'milk' from soya bean Prof M Sreenivasaya, who was one of the pioneers in enzyme chemistry during the early years of the Biochemistry Department, described the elegant method developed by him for the study of enzymes both by the ultra-micro- as well as by micro-dilatometric methods

Sixty-nine original research papers were presented at the symposia, and only a selection can be mentioned here

M G Bhat, of the Indian Institute of Science, read a paper on the nutrition and metabolism of *Pseudomonas convexa* var *hippuricum* representing the work done by her in collaboration with Drs T Ramakrishnan and J V Bhat Detailed investigations with regard to the nutritional requirements and metabolic pathways of this organism, which was isolated from soil using the enrichment culture technique, were outlined and a new pathway of benzoate breakdown by the bacteria involving salicylate, a mechanism different from the classical scheme of the metabolism of the aromatic ring, described M K Subramanyam (Indian Institute of Science) gave a résumé of his studies on the cytology of yeast, which included the demonstration of the presence of a nucleus and a vacuole as well as the occurrence of nuclear and vacuolar membranes in the yeast cell He also pointed out the general similarity of the structures of yeast and plant nuclei

M Chakravorty and D P Burma, of the Bose Institute, Calcutta, presented a paper on "Microbial Synthesis of Protein in Relation to the Biogenesis of Nucleic Acids" Using phosphorus-32 and sulphur-35, they have shown that, in the resting cell of *Azotobacter vinelandii*, conditions under which nucleic acid synthesis is inhibited lead to a decrease in protein synthesis On the contrary, it was found that the incorporation of phosphorus-32 into the nucleic acid continued in an uninterrupted manner even when protein synthesis was inhibited P S Sarma and co-workers, of the University Biochemical Laboratory, Madras, working on metal requirements of nicotinamide deaminases, have investigated the inhibition by metal-chelating agents of nicotinamide-deamidating systems in cell-free extracts of micro-organisms and the soluble fractions of pigeon liver. A study of the reversal of the inhibition, produced by α-α′-dipyridyl with various metal ions, has shown that the enzyme systems in the insect *Corcyra cephalonica* St , pigeon liver and chick kidneys are reactivated by Fe^{++}, that in *A niger* by Mg^{++} and the one in *N crassa* by Mn^{++}.

The detection and purification of a stereo-specific dihydrolipoic acid dehydrogenase formed the subject-matter of an interesting paper by D K Basu and D P Burma, of the Bose Institute, Calcutta The enzyme, which was purified 60–70-fold, was found to be diphosphopyridine nucleotide-linked and specific for dihydrolipoic acid and its amide The reaction was irreversible when tested with lipoic acid as the substrate I S Bhatia and co-workers, of the Tocklai Experimental Station, Cinnemara, Assam, gave an account of their work on the transglycosidase present in tea leaves This enzyme reacted with maltose with the formation of maltotriose, maltotetrose and glucose With arabinose as the acceptor of glucosyl residues and maltose as the donor, a disaccharide containing glucose and arabinose was formed

The purification and properties of glutamic–oxalacetic transaminase from ox brain and from human brain were described by T N Pattabhiraman and B K Bachhawat, of the Christian Medical College, Vellore A 30–40-fold purification of the enzyme was achieved by fractionating the initial extract with alcohol, Zn^{++} and ammonium sulphate The purified ox-brain transaminase showed complete dependence on pyridoxal phosphate for its activity

A new type of enzymatic transamination reaction in which glyoxylate transaminates with a number of amino-acids to produce glycine was reported by L V S Sastry and T Ramakrishnan (Indian Institute of Science) *Iso*nicotinic acid hydrazide and L-penicillamine at low concentrations inhibited the enzyme but the inhibition was reversed by pyridoxal phosphate or metal The authors adduced unequivocal evidence to show that the transaminase was a metallo-enzyme The purification and properties of a naturally occurring inhibitor of glutamine synthesis present in *Pongamia* galls was described by N K Sukanya and C S Vaidyanathan (Indian Institute of Science) , they also showed the preponderance of this inhibitor in the gall tissue, as compared to normal tissue

N Appaji Rao, H R Cama and S A Kumar (Indian Institute of Science) gave details of some of their recent work on the occurrence of flavin nucleotides in plants and the changes in their concentration with germination of green gram (*Phaseolus radiatus*) and cow pea (*Vigna catiang*) The radicle of the germinating seedlings contained almost all the flavin adenine dinucleotide and the major portion of the total flavin, while the cotyledons and the plumules contained flavin mononucleotide as the major flavin Some interesting examples of species specificity in the mechanism of pyridine nucleotide synthesis by erythrocytes were reported by P G Tulpule, of the Nutrition Research Laboratories, Hyderabad Of the seven species studied by them only human and guinea pig erythrocytes were capable of synthesizing diphosphopyridine nucleotide from nicotinamide and glucose Human as well as monkey erythrocytes could also synthesize appreciable amounts of diphosphopyridine nucleotide from nicotinic acid and glucose in the presence of glutamine, whereas this metabolic pathway did not seem to operate in the guinea pig Red blood cells of the monkey were able to synthesize diphosphopyridine nucleotide only in the presence of glutamine, suggesting that nicotinamide was converted to nicotinic acid prior to incorporation in diphosphopyridine nucleotide

Four special lectures were given in the evenings on each day of the symposium Dr D. P Burma, of the Bose Institute, Calcutta, on "Pentose Phosphate Metabolism", Dr B K Bachhawat (Christian Medical College) on "Purification of Enzymes" , Dr P M Bhargava (Regional Research Laboratories, Hyderabad) on "Protein Synthesis" and Dr T Ramasarma (Indian Institute of Science) on "Coenzyme Q" P S Sarma

NATIONAL VEGETABLE RESEARCH STATION

NEW LABORATORY BUILDING

THE new laboratory building of the National Vegetable Research Station was officially opened on October 23 by H R H The Duke of Edinburgh

The decision to establish the Station was taken after the Second World War because of a continuing need to encourage vegetable production in Great Britain, and the Agricultural Research Council is now responsible for government grant-aid to finance the Station and for the general supervision of its scientific programme

The new building marks the culmination of ten years development from the time when the director, Dr J Philp, took over 280 acres of land at Wellesbourne, near Warwick, in September 1949 Initially the site had no electricity, roads or suitable water supplies, and the only buildings were three small cottages and a few farm buildings Building restrictions in the early years severely hampered development and the research staff had to be housed temporarily in old service huts, while Dutch light structures served as temporary glasshouses

The new laboratory building was designed by Mr F W Holder, chief architect of the Ministry of Agriculture, Fisheries and Food, and has a total floor area of 33,800 sq ft Besides laboratories and offices it contains a library, lecture room and committee room, and the basement has space for the future provision of controlled-environment chambers The construction uses pre-cast concrete frame and floors with external curtain-walling of insulated plastic and some brickwork, the roof being of copper The Station also has about a half-acre of glasshouses used for pot-experiments in research projects, a packing shed, implement shed, farm stores and buildings for livestock 170 acres are served by underground irrigation mains with a borehole for the water source

The site at Wellesbourne is central for the country as a whole and the soil and climate are suitable for vegetable production, being similar to those in the nearby Vale of Evesham, an important horticultural area The area of 280 acres, to which 95 acres have

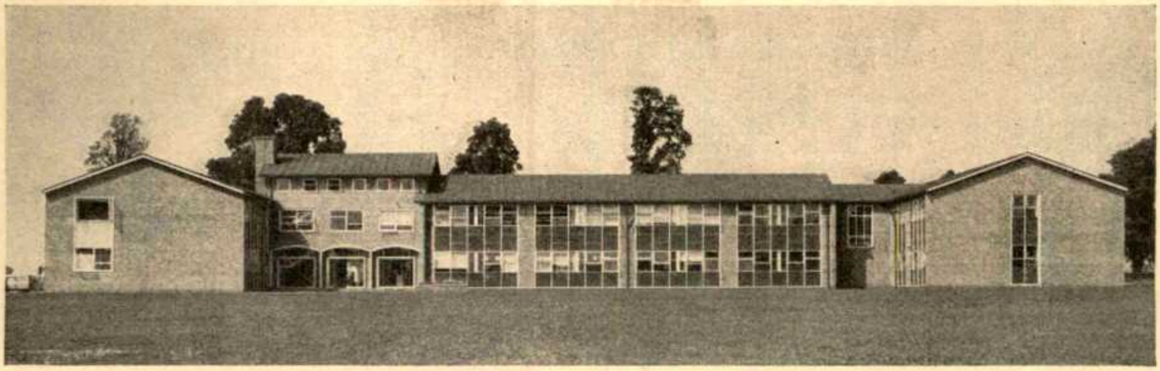

Fig. 1. New laboratories of the National Vegetable Research Station

recently been added, allows a farm unit to be run in conjunction with the experimental vegetable crops and is large enough to provide the isolation necessary for some of the research work. In addition, there is a sub-station at Paglesham, Essex, with an area of 150 acres, which is chiefly used for the multiplication of seed stocks.

All vegetable crops grown in the open and in cold frames, except potatoes, come within the purview of the Station, and its work is organized under eight sections: plant breeding; chemistry; physiology; irrigation; entomology; pathology; weed control; statistics.

Long-term experiments with a rotation of vegetable crops are now in their sixth year. The treatments comprise organic and inorganic fertilizers, time and frequency of application of nitrogen, and methods of soil cultivation. Growth studies are being made on some of the crops in these experiments to obtain information on the stages of growth most affected by fertilizers; the weed populations and soil-moisture characteristics of the soils under different cultivation methods are also being investigated. Dung has been shown to exert a marked influence on growth during the very small seedling stage.

Plant-breeding is carried on at a practical level with the production of improved varieties of vegetables, and at a more fundamental level with the application and development in vegetable crops of breeding methods as such. The method of inbreeding to attain uniformity followed by crossing to restore vigour, used so successfully in maize, has been applied to brussels sprouts, and hybrids with yields 40 per cent above the parent strains have been produced. The backcross technique is being used for the introduction of winter hardiness into an otherwise satisfactory quick-freeze variety of pea. In the diœcious species, asparagus, where the male plant is commercially desirable and usually heterogametic, isolation of homogametic male plants has produced strains giving all-male progeny on crossing.

Entomological research is mainly concentrated on the carrot fly, the cabbage-root fly and the lettuce-root aphid. Ecological work on the effect of insecticides on the balance between the cabbage-root fly and its predators has shown that the balance can be tipped in favour of the pest by indiscriminate broadcast application of insecticides. The use of insecticides against carrot fly raises problems of off-flavours in the crop and of the possible build-up of insecticides in the soil. Extensive testing tests have been carried out at the Station with carrots to assess the effect of insecticides on their flavour. A technique which has been developed for the assay of insecticide residues in the soil enables concentrations of dieldrin as low as 0·05 p.p.m. of soil to be measured.

The diseases of vegetable crops are as diverse as the crops themselves. The silvering disease of red beet, which is bacterial, has been successfully controlled with streptomycin. Fungal diseases include the long-known club root of brassicas and the relatively new crook-root disease of watercress; new fungicidal techniques give hope of controlling both these, while the prevention of virus diseases in watercress and lettuce is being sought through the production of clean stocks. The development of resistant varieties by selection and breeding techniques is being tried for parsnip canker and *Didymella* stem rot of tomatoes.

Work on the irrigation of vegetables has been primarily concerned with the most efficient use of water. Moisture-sensitive periods during growth have been found to exist with some vegetable crops, and at these periods irrigation has its maximum effect, while at others it does not produce an economic response. Work has been started on the relationship between water and nutrient uptake in the root system and on the use of additives to irrigation water.

The newer residual herbicides are being tested for suitability on a wide range of vegetable crops, and work has recently started on the nature and extent of the damage to vegetable crops caused by the drift of spray from herbicides used on neighbouring agricultural crops. The effects of weeds are also being studied in two other aspects: the unevenness of weed distribution has been shown to be partly responsible for field-plot variation in the yields of experimental crops, and the reduction in crop yields caused by weeds has been found to be affected by the spatial arrangement of the crop plants. Suitable mathematical models to describe the growth of some crop plants are being sought, with the view of improving the interpretation of treatment-year interactions in long-term experiments.

On the practical side, the Station maintains close links with the National Agricultural Advisory Service, and is fortunate in being able to make use of the experimental horticulture stations of this body for the further testing of experimental findings under a wider range of conditions. On the academic side, an arrangement with the University of Birmingham enables postgraduate work carried out at the Station to be recognized for the purpose of obtaining internal higher degrees of the University.

J. A. Nelder

THE GRASSLAND RESEARCH INSTITUTE

In the past, grassland has received much less than its due share of attention from the scientist, but some of the extensive work on this subject now being done in Great Britain is summarized in the recently published annual report for 1957–58 of the Grassland Research Institute (Experiments in Progress, No. 11. Pp. 108. Hurley, near Maidenhead: Grassland Research Institute, 1959. 7*s.* 6*d.*). Many aspects of the composition, treatment and use of grassland swards are investigated by the nine departments. The Department of Herbage Agronomy is concerned with management, yield and quality of herbage at all seasons of the year, and the emphasis has shifted from comparison of species and varieties to establishment and management of the sward. Continuation of the study of the relationship between white clover and top-dressings of nitrogenous fertilizer has shown that the effect of white clover on gross yield of herbage was equivalent to approximately 9 cwt. per acre of a nitrogenous fertilizer annually on a no-clover sward. The results of experiments with gibberellic acid showed that response to nitrogenous fertilizer at 4 cwt. per acre was greater than response to 2 oz. per acre gibberellic acid. Nitrogen plus gibberellic acid produced an additive effect at first, but in the presence of nitrogen there was a significant depression in yield as a result of gibberellic acid treatment; depression was greatest where the initial response to gibberellic acid was marked.

In the Section of Animal Agronomy, grassland production is measured in terms of the animal. Better live-weight performance per animal was obtained when cocksfoot was grown with lucerne than when lucerne was grown alone. A comparison of two methods of sowing and managing lucerne and cocksfoot indicates that it is possible to extend the grazing season by about four weeks in the autumn by use of nitrogenous fertilizers. The live-weight gain per acre of ewe lambs carried throughout the year at a stocking rate of 6·1 per acre was, on average, 65 lb. higher on swards containing white clover, although the grass swards received nitrogen to compensate. The comparative influence of leys, variously managed, on the yield of subsequent cereal and kale crops has been investigated by the Department of Ley Agronomy. It is demonstrated that management of ley swards has an appreciable effect on yield of the following crops. This is accounted for largely by the nitrogen status of the soil. The study of the intake and digestibility of herbage is one of the main concerns of the Department of Biochemistry and Animal Nutrition. This involves both feeding experiments and biochemical studies of herbage plants. The former have shown that certain of the major grasses are more digestible than others and the latter that the older methods of fractionation are too arbitrary; modern techniques are likely to give a more reliable assessment of digestibility.

The work of the Department of Plant Physiology is linked with that of Herbage Agronomy in laboratory and field. The detailed growth studies are likely to provide valuable guidance on grazing practice. Experiments in microbiology are connected to soil and herbage studies in other departments, with emphasis on the examination of the processes of decomposition which take place when the ley is ploughed. A small experiment on sterilization of grass by radiation suggests that it may be possible to preserve grass for several months without undue changes in palatability. Extra-mural experiments provide supplementary evidence over a wide variety of environmental conditions. Such experiments are usually done in collaboration with the National Agricultural Advisory Service. The Department of Biometrics provides statistical advice and a computing service for other departments and has commenced its own field-experiments to answer specific questions.

SCIENTIFIC RESEARCH IN ALBERTA

The thirty-ninth annual report of the Research Council of Alberta, covering the year 1958, stresses the work on ground water geology and the studies on the Precambrian Shield area of north-east Alberta (Report No. 78. Pp. 66. Edmonton: Research Council of Alberta, 1959). Work was commenced on the delineation of areas with large coal reserves which could be developed by industry as a source of power, and reconnaissance surveys were made of alkali lakes in Alberta and of the mountains west of Nordegg. A laboratory study of till from the Cooking Lake moraine showed that electrical potentials up to 0·5 V. can be generated in soil between individual horizons by natural processes. Soil surveys continued and a study is being made to determine the characteristics of the dominant parent materials of Alberta soils, the composition of the glacial till and the local variations. Further work at Youngstown showed that the productivity of the solonetz soils was limited by the physical condition of the soil, times and timeliness of irrigation being both critical under such soil conditions. The hail reporting network was further extended and valuable results were obtained in spite of an unusually low incidence of hail in the area. The highway research programme was largely concerned with the instrumentation and study of a five-mile portion of the trans-Canada highway west of Calgary, on which test sections of three different types of concrete pavement were laid.

Fundamental studies on coal in the organic chemistry laboratory included an examination of reactions of humic acids, a preliminary survey of the properties of kerogens and other organic substances associated with inorganic sediments, and substantial progress in the separation of the products obtained by oxidizing pyrolysed truxene with nitric acid. The main effort of the physical chemistry laboratory was in studies of the mechanism of thermal decomposition of coal and the control of the decomposition by gaseous and gas-entrained additives; but the effects of ultrasonic irradiation on small molecules were also examined and the viscosity characteristics of solvent extracts from coal and the shape and size of the extracted molecules In palæobotany, substantial progress was made in formulating means for identifying fossil spores and pollen grains, and the development of a 'key' for identifying living and fossil conifer woods is now virtually complete Further studies are reported on fluidized carbonization, and the first stage of a coal grindability investigation was completed In the petroleum division studies continued of the catalytic desulphurization of sulphur compounds at high temperatures to remove sulphur as hydrogen sulphide and on the oxidation of sulphur compounds to remove it as sulphate The study of two-phase flow of oil and water in pipe-lines was continued, in which a general mathematical analysis was developed for two immiscible fluids flowing between wide parallel plates and flowing concentrically in a circular pipe Considerable progress was made in the study of the effects of hydrogen isotopes on the rates of chemical reactions, while the study of the retention volumes of hydrocarbon gases on chromatographic columns of a series of activated charcoals has been extended to an examination of the relative widths of the chromatographic bands The autothermic surface combustion reactor for pyrolysing hydrocarbons was further developed A list of publications of the Council is appended

BIOLOGY OF *AMŒBA*

THE late Robert Chambers was a much-loved personality on both sides of the Atlantic A publication by the New York Academy of Sciences has been greatly influenced by him, many papers being presented by his former students and 'second generation' of students* The papers deal exclusively with the 'fission cycle' of the life-history of Amœba I first made acquaintance with Chambers when studying *Daphnia pulex*, each having worked out its spermatogenesis Later, I sent to him supplies of *A proteus* at various localities

An article by Mazia in "Science in Progress"[1] prepared readers for some of the many good things in this volume After a short biography of Chambers and an introduction by Hirshfield, the subject-matter is grouped into four parts In part 1 ("Structural and Taxonomic Considerations"), Torch describes the cytology of Pelomyxa The most interesting conclusion is that crystals are a metabolic waste product, probably an accessory mechanism for the excretion of nitrogen Particulates of Amœbæ are studied by Kassel using a drop-retraction technique , proteins on reaching an experimentally introduced oil–water interface unfold and produce a surface denaturation curve resembling that of a medium containing a protein of low molecular weight Useful practical hints and photographs of apparatus, as well as electron microscope studies, are given in "Microscopic Studies" by Borysko and Roslansky Beautiful electron microscopic work by Pappas reveals the astounding presence of fine fibrous extensions on the outer surface of the plasmalemma of three species of amœba, and other unsuspected structures Kudo gives a welcome résumé of the work of the early observers and their nomenclature and makes a strong plea for the retention of the name *Amœba* for the genus

In part 2 ("Physical Studies and Cell Division") Landau deals with sol–gel transformations in Amœbæ, and considers that the findings of myosin-like proteins in amœboid forms lend credence to the idea of a contractile substratum "Synchronization of Cell-Division" by James gives much fascinating detail of the observations made during the establishment of the main thesis Three authors describe pinocytosis, which was discovered by Lewis, and observed by Mast and Doyle in amœbæ, but only recognized as important in the past few years Holter, in the next paper, gives some beautiful pictures of the phenomenon, and stresses its importance in the physiology of amœboid cells, though he thinks that the original definition may require modification towards less emphasis on the fluid uptake and more on the dissolved substance

A very long paper of sixty-three pages by Guthwin and Kopac is a vade-mecum for the microscopic enzyme chemistry of carboxylic esterases in Amœbæ "Cytochemical Differentiation in Normal and Starving Amœbæ", by Heller, is the second article of part 3 An interesting analysis of the cytoplasmic inclusions deals with refractive bodies As I have repeatedly pointed out, these refractive bodies are nutritive, and for that reason Dr Carmela Hayes renamed them 'nutritive spheres' They play a great part in the formation of the spores in the Proteus group of Amœbæ Their diameter is indicative of the age of the Amœba—an individual with large nutritive spheres is old and ready to sporulate Cohen, in "Physiological and Morphological Observations", gives the first hint as to the great weakness of the work under review when he says, "*A proteus* in our experience consists of at least two strains investigators should give the history of the stock they use" I maintain that two distinct species masquerade under the specific name *proteus* I have had an opportunity of studying a rich culture from the laboratory of Brachet it was *A lescherae* and not *A proteus* It also contained very young stages of development, proving that even under rigid subculturing a few individuals escape and sporulate Want of space prohibits more than mention of "Tracer Studies in Amœbæ" by Plaut, "Effect of Selected Chemical Agents on Amœbæ" by Zimmerman

In part 4 Hirshfield discusses "Nuclear Control of Cytoplasmic Activities" and Prescott pictures the wonderful Cartesian diver for weighing Amœbæ in his article on microtechnique in amœbæ studies "Micrurgical Studies on Irradiated Pelomyra", by Daniels, is followed by an account of the celebrated work of Danielli on strains of Amœbæ that have been continuously cultivated for years in King's College, London In conclusion, one would urge the examination of older Amœbæ for the presence of deoxyribonucleic acid Brachet's beautiful work on the "Cytoplasmic Dependence in Amœba" evidently omits this The volume ends on a lighter vein when Kopac visualizes Amœba research in 2158 Used in conjunction with Jepps's "The Protozoa, *Sarcodina*"[2], this volume is a useful reference book for all students of *Amœba* MONICA TAYLOR

VALUE OF CONTOUR ANALYSIS IN EQUATORIAL METEOROLOGY

By D. H. JOHNSON and D. H. T. MORTH
East African Meteorological Department, Nairobi

SINCE November 1958, daily contour analyses have been made at the East African Meteorological Department, Central Forecast Office, East Africa, for standard pressure-levels from the surface to 100 mb., and for an area which includes all Africa, and Europe to 55° N. Such analyses are believed to be unique for Africa: they are giving an insight into mechanisms governing equatorial weather which has not been provided by conventional streamline analyses of the upper winds.

Flow and changes in the flow are as dependent in the tropics as elsewhere on the pressure field and its evolution. However, the want of radiosonde data, lack of success in explaining day-to-day variations in weather in terms of the surface pressure field, and the absence of a fixed relation between pressure gradient and wind, have led to a concentration in the past decade on streamline analysis alone. Streamlines define usefully the instantaneous wind but they have failed in everyday use in East Africa to account satisfactorily for the observed weather, and they have contributed little by themselves to the solution of forecasting problems. Improvements in radiosonde and radar wind coverage over Africa, due largely to the stimulus of the International Geophysical Year, now permit some deductions regarding the role of the upper pressure distribution to be made.

Principal points of contrast with middle-latitude upper patterns are: (*a*) equatorial pressure gradients are weak, a consequence of the inability of other terms in the equations of motion to balance a large pressure force in the free atmosphere; (*b*) pressure systems which influence East African weather are slow-moving or stationary and weather changes are effected more often through development *in situ* than by travelling disturbances.

Though the observations are still insufficiently dense and accurate to define the contours precisely, certain characteristic states have been recognized. An important case arises when upper anticyclones in the lower latitudes of each hemisphere are separated by a trough along the equator (Fig. 1). This system is associated with zonal flow. Pressure gradients and winds derived by assuming a geostrophic balance agree well with observations. When the contours are confluent as in the right of Fig. 1, acceleration leads to convergence near to the equator, and if the convergence extends in depth through the lower layers, a rain-producing mechanism exists. Understandably, the most marked effects on the weather occur when the pressure field is not stationary, but either or both of the anticyclones change their intensity or location; the accelerations are then potentially greatest since the geostrophic balance is particularly delicate due to the smallness of the Coriolis parameter.

A second well-defined model occurs when a meridionally directed pressure gradient exists across the equator (Fig. 2). The geostrophic departure increases as the equator is approached and the unbalanced pressure force at the equator itself leads simply to down-gradient (Eulerian) flow: the contours are crossed perpendicularly by the streamlines a few degrees downstream of the equator, the lag being due to the zonal momentum carried. This model was observed primarily in the period January–March 1959 when, in the lower troposphere, the low pressure to the south took the form of a zonal trough. Cochemé[1] has remarked on the predominance of this pattern near the surface during February 1955 and has noted the resemblance to the large-scale monsoon flow associated with the Indian summer low pressure. On other occasions the low pressure is the equatorward portion of a large-amplitude trough in the polar westerlies which has penetrated the subtropical anticyclonic belt. This pattern was typically associated with lower divergence and fine weather north of the equator and with rain in the convergent westerlies to the south.

The foregoing two cases have been illustrated in simple form, but smaller-scale complications, some orographic, some developmental, may be superimposed upon them, and the two patterns can co-exist in adjoining longitudes. Other characteristic states arise. Of particular importance are those which give rise to westerlies in the lower half of the troposphere. East African meteorologists have long recognized an association between westerly winds and widespread rain. Previously this has been ascribed to the presence of a source of moisture to the west. We observe, however, that a more than adequate supply of moisture is carried inland in the lower layers of the easterly monsoon currents, and consider this to be the more important moisture source for East African rainfall. Westerly flow is often simply

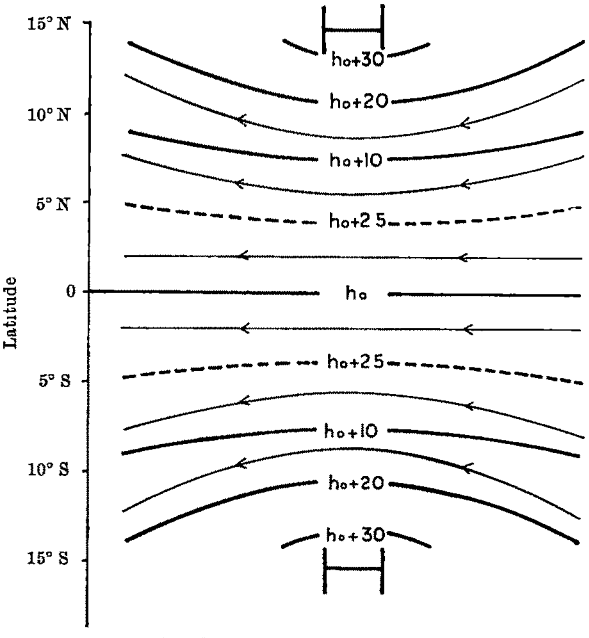

Fig. 1. Equatorial duct. —, Contour line (height in m.); —←, streamlines

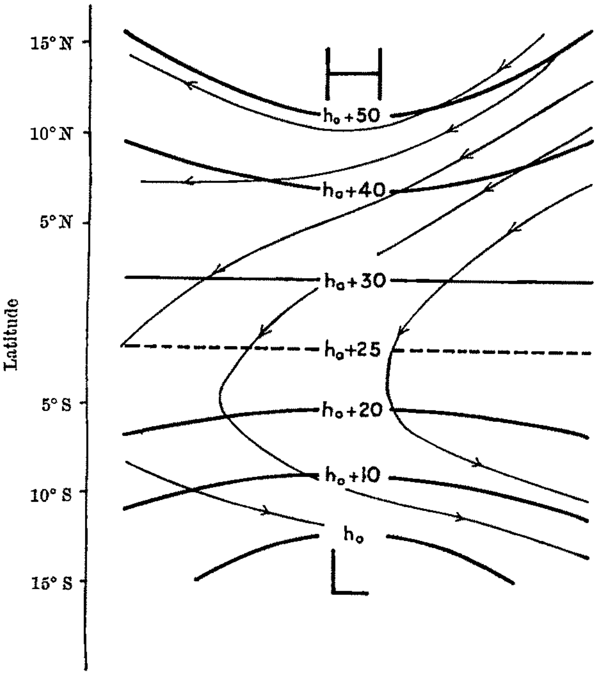

Fig 2 Cross-equatorial drift —, Contour lines (height in m), →—, streamlines

a recurving easterly monsoon current. A basic tendency for moisture to be contained in the lower layers in easterlies, due to subsidence, and for upward transport of the moisture in westerlies, is ascribed to the operation of the Coriolis term, $2\Omega\cos\varphi\, u$, in the equation for the vertical acceleration

$$\frac{dw}{dt} = -\alpha\frac{\partial p}{\partial z} - g + 2\Omega\cos\varphi\, u$$

where the symbols have their conventional significance. Considering a fixed value for u, the term $2\Omega\cos\varphi\, u$ has its maximum at the equator. It has usually been dismissed as being negligibly small[2] in comparison with the pressure gradient and gravity terms, but these oppose each other, being approximately in balance. In these circumstances smaller terms can achieve significance. Calculation of the last term shows that, providing the possible compensating mechanisms only partially diminish the instantaneous acceleration, appreciable vertical motions could build up on the time-scale of synoptic processes. The effect is by no means over-riding and may be opposed or enhanced by the synoptic situation.

The importance of examining pressure and flow patterns at several levels of the lower troposphere when assessing the significant vertical motions was amply demonstrated during May 1959. Marked low-level divergence over Kenya and Tanganyika, in the outflow from the surface/850 mb Mauritius/Madagascar sub-tropical anticyclone, underlay on different occasions a confluent 700 mb pattern (Fig 1) and a weak westerly flow, in both cases no rain fell.

As recently as December 1958, the opening speaker at a Meteorological Office discussion on tropical meteorology[3] remarked that the forecasting of upper winds from prontours is invalid in equatorial regions because a relationship between contours and wind has not been established. Contrariwise, the present work, which raises hopes of a basically synoptic solution to East African weather forecasting problems, suggests that the ability to predict changes in the contour pattern in low latitudes is a fundamental need. We most strongly disagree with the view expressed by Walker in the same discussion[3] that there is no guarantee that an improved upper air network would improve (equatorial) forecasting significantly. In a paper which has very recently come to hand, Palmer and collaborators[4] have proved the occurrence of approximately geostrophic flow down to equatorial latitudes in the Pacific Trades, their investigation demonstrates most eloquently the value of a close homogeneous network of radiosonde and radar wind observations in solving the problems of equatorial flow. the establishment of a similarly close network in East Africa and adjoining territories, where a greater variety of pressure patterns and far more synoptic change occurs, would, we contend, lead to fundamental progress in our understanding of equatorial weather mechanisms.

We wish to thank Mr B W Thompson, regional meteorological representative, Kenya, East Africa, for his constant support and advice, and Mr J P Henderson, director, East African Meteorological Department, for permission to publish this account.

PERMANENT MOISTURE EXPANSION OF CLAY PRODUCTS ON NATURAL EXPOSURE

By J S HOSKING and H. V HUEBER

Division of Building Research, Commonwealth Scientific and Industrial Research Organization, Graham Road, Highett, S.21, Victoria, Australia

THE criticisms by Vaughan and Dinsdale[1] of our communication[2] on the progressive long-term moisture expansion of clay products, and their objection to our use of the term 'permanent' to describe it, lead us to fear that they still regard the problem as one of academic interest only and not as a serious practical one, such as our observations of damage to buildings in Australia[3] and those of McBurney[4] in the United States of America have shown it to be. Although the expansion may apparently be removed by subjecting the materials to high temperatures, it is permanent at atmospheric temperatures, and hence as long as we are considering the problem as a practical one

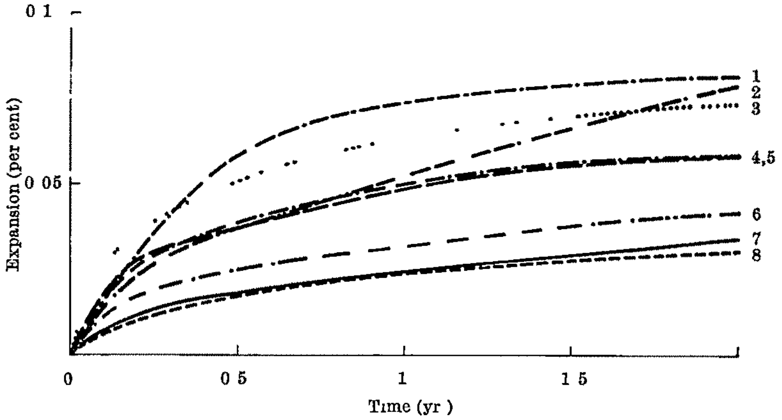

Fig. 1. Average permanent moisture expansion curves for eight types of clay product on standing in air for two years. Curve 1, roofing tiles; curve 2, wall tiles; curve 3, architectural terra-cotta; curve 4, bricks; curve 5, china body; curve 6, refractory body; curve 7, floor tile; curve 8, firebrick

the expansion can properly be referred to as permanent.

Our main object in studying the problem is to determine, for a wide range of clay products, the ultimate expansions and the times taken to reach these, whether they be 50, 100 or 1,000 years. A knowledge of both is necessary if we are to find out how to offset the expansion and so prevent the resultant damage. The reason that we, like others, have autoclaved the bodies in steam has been to accelerate the process of expansion and thus to study, in a reasonable time, the reactions which normally take a life-time or more. Unlike others, however, we have continued the process of autoclaving until the bodies reached dimensional stability and have thus obtained measures of the maximum expansions the bodies suffer at high temperatures. At the same time, we have not neglected to observe the bodies under natural conditions, for it is only thus that the practical behaviour of the bodies can be correlated with the results at high temperatures.

In all, we now have more than a thousand industrial and laboratory specimens exposed under natural conditions, and these are being added to from time to time. Replicate samples are exposed, out of doors, in an air-conditioned laboratory and in an atmosphere of 100 per cent relative humidity, while others are kept totally immersed in water; others again have been subjected to cycles of soaking in water and drying at 110° C. Some bricks have now been under observation for five years, at the end of which time they show expansions ranging from 0·045 to 0·20 per cent with an average rate still between 0·005–0·006 per cent per annum. Most products have been under observation for shorter periods, and the average and range of the expansions for the eight types of body for which results on autoclaving have already been reported[2], after standing for two years either in the laboratory or out of doors, are given in Table 1. Curves for the average expansion of the products with time are given in Fig. 1. Because of the small number of some of the products so far examined the values cannot be considered as completely characteristic, but they do indicate the general trends for the various bodies.

Our results show that the expansions on standing in air are higher than those predicted from the temperature coefficient of the expansion process based on high temperature data[2], and from this and other observations it is clear that there are no practical relationships between autoclave and low-temperature data[3]. Estimates of ultimate expansions likely in practice and the times to reach these have therefore to be based on the results obtained for natural exposures to date, and as they come to hand in the future.

From our experience we are not surprised that specimens used by Vaughan and Dinsdale did not reach equilibrium during relatively short periods of either natural exposure or autoclaving. Standing for three years is a long way short of the periods for which we know that bodies can continue to expand[3], and calculations based on the temperature coefficient of the expansion process[2,3] show that times of the order of 12,000 hr. would be required if the bodies are to reach dimensional stability in steam at 50 lb./sq. in.

We have observed shrinkages on drying as reported by Vaughan and Dinsdale only in under-burnt bodies, and then only on drying after more than one cycle of wetting and drying; these shrinkages are, however, always less than the original expansions on wetting. Normal ceramic bodies have, in general, continued to expand on drying at 110° C whether they have been soaked in water or treated in the autoclave[3]. This has also been the experience of other workers[5], and Bonnell and Butterworth[6] have found that no less than 50 per cent of the bricks of the United Kingdom expanded when tested for drying shrinkage. Only when specimens have been autoclaved until they approach dimensional stability (far beyond the stage to which Vaughan and Dinsdale's specimens were taken) do drying shrinkages become apparent, and then only of the order of 0·01–0·02 per cent, a mere fraction of the total expansion. In this connexion it is of practical significance that all nine experimental walls which have now been standing for more than three years at this Division expanded at slightly higher rates when drying out during the hot summer months[3]. The explanation for this is simple: it is due to the increased rate of reaction between the reactive compounds in the bricks and the water still present at the higher temperatures during the drying out process.

Vaughan and Dinsdale's observation that a complete reversal of the change in size can be obtained by heating to 300° C suggests that they have not investigated a very wide range of bodies. This

Table 1. PERMANENT MOISTURE EXPANSION FOR EIGHT TYPES OF CLAY PRODUCT STANDING IN AIR

Product	No. examined	Expansion	
		Average (per cent)	Range (per cent)
Roofing tile	94	0·082	0·162–0·009
Wall tile	18	0·079	0·094–0·066
Architectural terra-cotta	12	0·074	0·098–0·059
Brick	260	0·061	0·186–0·010
China body	6	0·061	0·110–0·034
Refractory body	6	0·042	0·080–0·023
Floor tile	12	0·034	0·080–0·014
Firebrick	12	0·031	0·045–0·020

phenomenon has been reported once before[7], but most other workers have found that temperatures of at least 600° C and often much higher are necessary for this purpose[8] In some cases it has proved impossible to remove expansion without heating to temperatures approaching and above those at which the specimens were originally fired At these temperatures further firing shrinkages occur and the two effects become confused , this suggests that even at lower temperatures the shrinkages obtained by reheating are not necessarily caused by a reversal of the expansion process, and hence any approximate numerical agreement may be quite fortuitous

Our critics also raise the question of expansion taking place during the cooling of the clay bodies in the kiln, and its effect on the establishment of a standard zero of measurement We are fully aware of this problem but do not see that their proposal of a preliminary desorption is of practical value The specimens will still have to be cooled after this treatment before they can be measured, and hence they will again adsorb moisture, and further, as we have pointed out above, most bodies if heated after they have adsorbed moisture expand still more We therefore consider that the small amounts of expansion in the kiln must be disregarded from the practical point of view What matters is the expansion that takes place in the structures into which the units are built, and therefore the practical basis for calculating and comparing expansions is the ex-kiln length of the products

From experimental evidence in this Division[2,3,9] we consider that chemical processes involving hydration of such constituents as amorphous alumino-silicates, glasses and amorphous silica are responsible for expansion, and that reversible physical swelling, except in under-burnt bodies, plays a very minor part Furthermore, we consider that the evidence presented by our critics does not substantiate a physical explanation

A full account of our work to date on bricks[3] is now available and we hope to present a summary of current studies on the expansion (under natural conditions of exposure) of all clay products examined so far to the seventh International Ceramic Congress in 1960

EXISTENCE OF AN INNER AURORAL ZONE

By Dr KNUD LASSEN

Danish Meteorological Institute, Copenhagen

FROM theoretical considerations Alfvén[1] predicted the existence of an inner auroral zone at a polar distance of 5–10° Nikolsky[2], Meek[3], and others have found that the maxima of geomagnetic and ionospheric disturbances are concentrated around a spiral-shaped zone which Nikolsky identifies with the inner auroral zone However, no observation of auroræ in relation to this zone seems to have been made , the spiral-shaped zone is presumably identical with the curve of geographical distribution of maxima of magnetic activity of class J[4] At Godhavn (69 2° , 306 5° geog) this class of activity is not at all, or very poorly, correlated with auroræ , hence the zone of Nikolsky, Meek and others can scarcely be regarded as an auroral zone in the proper sense

It is the purpose of this article to direct attention to a 'population' of auroræ which seems to form an inner auroral zone , it summarizes a study which was presented in part at the Auroral Conference at Uppsala in August 1958 A more detailed paper will be published elsewhere

As a result of visual auroral observations at Godhavn during 1952–56 it was found that the diurnal distribution of auroral frequency there had two maxima In fact, the distribution is composed of two distributions of different types One, with a maximum near magnetic midnight, is formed by relatively brilliant auroræ, approaching and sometimes passing zenith from the south-east, accompanied by negative magnetic bays These auroræ are especially frequent and brilliant on international disturbed days and in years with low sunspot activity

The second distribution with a maximum at about 6h local time is formed by zenithal auroræ These are narrow diffuse bands, sometimes with a faint ray structure, or draperies—often several parallel draperies—composed of long rays that may be at some distance from each other The draperies may form fans or coronas, occasionally accompanied by colour effects, but generally the movements of the arcs and rays are very moderate They may rather be described as slow pulsations of intensity , narrow homogeneous arcs slowly die away, while parallel arcs a few degrees from them grow in intensity These slow variations may go on for a long time , they seem quite irregular and not in phase in the different arcs or rays, so that the mean position of the aurora is little affected by the intensity variations

Several authors have assumed that the main auroral zone is displaced polewards in the morning hours There is no observational evidence that this is the reason why auroræ are observed at Godhavn in the morning hours On the contrary, in the cases where the onset of the morning-type auroræ was observed, very weak auroræ began sporadically at a great elevation at about 3h –4h (Ascagrams from the International Geophysical Year, too, show that the auroræ begin suddenly within a few degrees from Godhavn) The mean elevation did not change significantly in the course of the morning , the mean distribution of the elevation of the arcs and draperies had its maximum a little to the south of zenith (Fig 1)

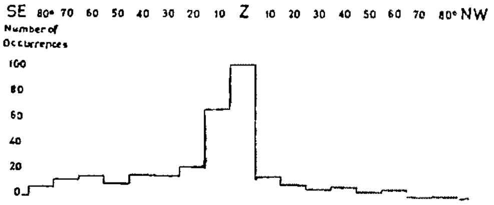

Fig. 1. Frequency-distribution of zenith-distances, Godhavn, 1954–56

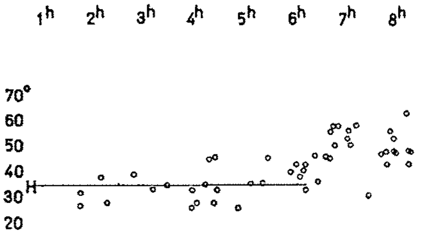

Fig. 2. Azimuth of arcs, Godhavn, 1954–56

The direction of the bands was perpendicular to *H* until 6h; at about 6h the mean direction suddenly changed in a clockwise sense (as seen from above). The change is consistent with Alfvén's theory[5]. The order of magnitude was 20° in 1954–56 (Fig. 2).

Whereas the evening-type auroræ are strongly related to magnetic activity, the morning-type auroræ are not correlated with local magnetic activity, and they appear to be independent of the planetary state of disturbance, too. Thus, observations from Upernavik, a few degrees to the north of Godhavn, from the years 1884–1937, show that auroræ noted at 21h L.T. were eight times as frequent on international disturbed days as upon international quiet days. Auroræ noted at 8h were here, as well as at Jakobshavn, a hundred kilometres to the east of Godhavn (observations 1885–1915), distributed at random between quiet, disturbed and the remaining days. At Godhavn auroræ were observed on 106 of a total of 110 clear mornings without moonlight in the winters 1954–55 and 1955–56.

A study of published auroral reports from arctic expeditions has shown that the morning-type auroræ observed at Godhavn can be found at several other locations too. Thus the auroral type mentioned was observed near zenith at Kingua-Fjord[6], and it seems likely that the same was the case at Chesterfield[7,8], Coppermine[7] and Murchison Bay[9]. Further, auroræ near zenith in the morning hours were observed at Danmarkshavn (76.5°, 341°), Station Nord (81.5°, 342°) and at a number of stations on the western coast of Greenland not very distant from Godhavn (unpublished observations, Danish Meteorological Institute).

To the south of Godhavn the auroræ seem to have been observed from Godthåb, whereas at stations in southern Greenland nearer to the main auroral zone this type of aurora has not been identified.

At stations nearer to the centre of the auroral isochasms (Peary Land, Upernavik, Thule) the morning auroræ are observed less frequently and mainly on the southern sky (unpublished observations).

In the Antarctic the inner zone auroræ were observed by several expeditions, for example, by Mawson at the stations Cape Royds and Cape Denison[10].

On the map in Fig. 3 (after Hultquist[11]) the places at which the morning auroræ are observed near zenith have been plotted as circles. They are seen to form a zone which is practically coincident with Hultquist's auroral isochasm through Godhavn. This oval, which is the projection of a circle in the equatorial plane outside the Earth on to its surface along the geomagnetic lines of force, may thus be regarded as an inner auroral zone, occupied in the early morning- and day-hours of all days, irrespective of disturbances in the main auroral zone.

Fig. 4 shows the diurnal distribution of auroral frequencies for December and January 1948–50 at five stations in Greenland. The stations are Thule

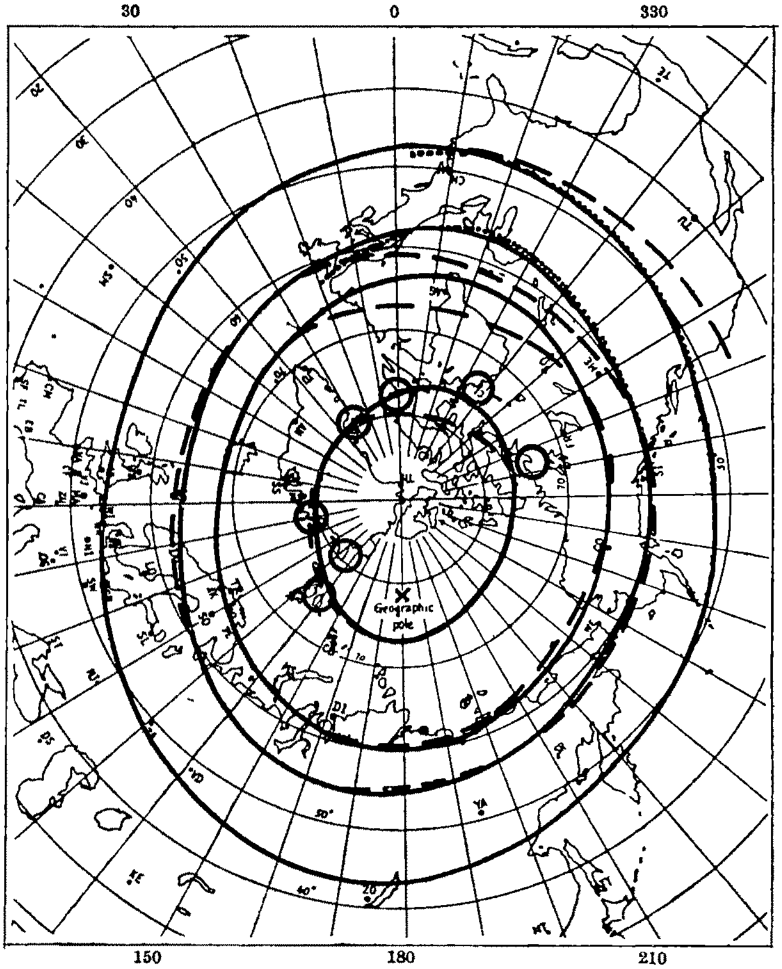

Fig. 3. Auroral isochasms (after Hultquist) and stations with morning auroræ near zenith

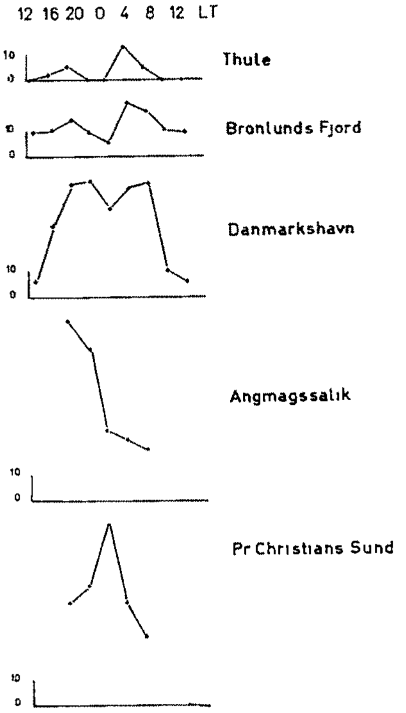

Fig 4 Percentage of clear hours with aurora at five stations in Greenland, December and January 1948–50

(76° 33′ N , 68° 49′ W), Brønlunds Fjord, Peary Land (82° 10′ N , 30° 30′ W), Danmarkshavn (76° 46′ N , 18° 45′ W), Angmagssalik (65° 36′ N , 37° 33′ W), and Prins Christians Sund (60° 03′ N , 43° 12′ W) The figure gives the percentage of clear hours with aurora, arranged according to local time , the same scale has been used at all stations Whereas the frequency of evening auroræ increases from Thule to Angmagssalik–Prins Christians Sund it is clearly seen that the frequency of the morning auroræ has its maximum at Danmarkshavn, in accordance with the idea of the existence of an inner auroral zone there

Hulburt[12], in his study of the diurnal variation of auroral frequencies, takes the view that "Vegard's conclusion, that most auroral forms show an evening and morning maximum, is contradicted almost as often as it is upheld" From Fig 4 (which is in agreement with material from several other stations) it may be seen that the different types of diurnal distributions can be arranged according to the following scheme (*a*) stations at the main auroral zone have distributions with a single maximum near geomagnetic midnight , (*b*) stations between the zones have often, in addition, a weak morning maximum , (*c*) stations near the inner auroral zone show two maxima, one near geomagnetic midnight and one at about 6h L T , (*d*) stations some degrees of latitude nearer to the pole show a weak geomagnetic midnight maximum and a distinct morning maximum

Great ionospheric disturbances begin at the same time as the onset of the morning auroræ The *F*-layer is dissolved into spread *F* and oblique incidences, which are soon accompanied by sporadic layers of auroral type at different virtual heights between the *E*- and *F*-layer heights Whereas observations of auroræ are restricted by cloud and daylight, a study of ionospheric disturbance is possible at any time The occurrence of ionospheric disturbance may be represented by the mean daily distribution of the frequency of $E_s > 3$ Mc /s , which is published monthly by the National Bureau of Standards By combining the frequencies for 3h–8h L T for the years 1952–56 it was found that the yearly variation of the morning disturbances is a single wave with a maximum at midwinter and a minimum at midsummer The variation through the whole period seems to indicate a variation in phase opposite to the sunspot variation

ISOMERS OF VITAMIN A IN FISH LIVER OILS

By PATRICIA S BROWN, WILLIAM P BLUM and MAX H STERN

Biological Laboratories, Harvard University, Cambridge, and the Research Laboratories of Distillation Products Industries, Division of Eastman Kodak Company

WE have investigated the occurrence of the '*iso-a*' and '*iso-b*' isomers of vitamin A in a number of fish liver oils by means of reaction with the retinal protein, opsin These isomers were found to constitute about 20 per cent of the vitamin A in cod, shark and mixed fish liver oils examined Since the presence in fish liver oils of all-*trans* vitamin A and neovitamin A (*neo-a*)[1] has previously been reported, all four of the 'unhindered' isomers have been found in these oils

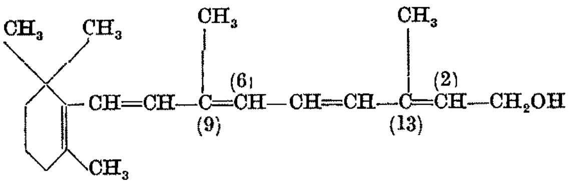
The finding assumes importance because the *iso-a* and *iso-b* isomers have only about one-fourth the growth-promoting activity of all-*trans* vitamin A, as measured by rat bioassay[2]

Nomenclature, structure and biopotencies for the *iso-a* and *iso-b* isomers are shown in Table 1

The trivial names devised by Hubbard and Wald[3] are used in this report because official action on a numbering system has not yet been taken The numbering systems now used include (*G*) Table 1,

Table 1

Trivial name	Stereoisomeric form		Relative biological potency (ref 2) (per cent) Vitamin A acetate	Vitamin A aldehyde (retinene)
	all-*trans*		100	91
	C	*G*		
iso-a	9-*cis*	6-*cis*	21	19
iso-b	9,13-di-*cis*	2,6-di-*cis*	24	17



the Geneva system used by *Chemical Abstracts*[4] and employed in earlier[2,5] and forthcoming papers from the Distillation Products Industries Laboratories and (*C*) the system analogous to that used with the carotenoids and employed by Wald, Brown, Hubbard and Oroshnik[6]

Hubbard and Wald[7] first reported the presence in a concentrate from fish liver oils of a *cis*-isomer of vitamin A different from the neovitamin A found by Robeson and Baxter[1] Later studies by Hubbard and Wald[3] on pure retinene (vitamin A aldehyde) isomers synthesized in the Distillation Products Industries Laboratories[5,8] showed that the isomer in fish liver oil was *iso-a* vitamin A The basis for the identification was the observation that both *iso-a* retinene and the retinene corresponding to the *cis*-isomer formed the same pigment with opsin, namely, *iso*rhodopsin, having an absorption band maximal at 487 mμ *Iso-b* retinene, on incubation with opsin, slowly isomerizes to *iso-a* retinene and forms the same pigment

This reaction was afterwards developed by Hubbard, Gregerman and Wald[9] as an analytical method for determining the *iso-a* and *iso-b* isomers in the absence of *neo-b* retinene The *neo-b* isomer, the key isomer in the visual process, interferes in this reaction by yielding the pigment rhodopsin, absorbing at 500 mμ The interference from *neo-b* retinene has not complicated studies on fish liver oils because this isomer has not yet been found outside the eye[10]

The results of applying this analytical procedure and an infra-red method to vitamin A preparations are given in Table 2

Four fish liver oil preparations (shark 'non-sap', that is, the non-saponifiable fraction, before and after concentration by molecular distillation, cod 'non-sap' and the 'non-sap' from distilled cod liver oil) were prepared (by M H S) and assayed by the opsin method (P S B) The test samples were saponified and the vitamin A isomers were recovered by extraction (U S P XV method) Sterols were separated by crystallization from methanol at −20° C The isomers were oxidized to the retinenes by procedures similar to those of Wald[11] with manganese dioxide prepared according to Henbest, Jones and Owen[12] The cod liver oil was a pharmaceutical preparation from an apothecary, the shark liver oil was from a bulk commercial shipment obtained at Distillation Products Industries Table 2 shows that 19–26 per cent of combined *iso-a* and *iso-b* isomers were present in the vitamin A of the oils

After further refinement of the procedures, the vitamin A of a pharmaceutical grade, mixed fish liver oil (sample 5, Table 2) was found to contain 19 per cent combined *iso-a* and *iso-b* isomers

The content of combined *iso-a* and *iso-b* vitamin A in a sample of oil from rat livers (sample 6, Table 2) was examined The value found (14 per cent) was lower than that found for the fish liver oil preparations examined, but was substantial and indicates that these isomers occur in other oils besides fish liver oils

The origin of the *iso-a* and *iso-b* isomers in fish liver oils is uncertain Ames, Swanson and Harris[13] have suggested, on the basis of bioassays of rat liver oils, that the isomers originate there from *in vivo* isomerization of all-*trans* or neovitamin A to form an equilibrium mixture A similar isomerization may occur in fish liver oils

Another possibility is that the '*iso*' isomers may sometimes be formed during processing of fish livers Lambertsen and Braekkan[14], for example, have reported evidence suggesting that neovitamin A is formed from all-*trans* vitamin A during commercial processing and it is possible that '*iso*' isomers may also be formed Pharmaceutical grade oils were used in the present study, where available, to ensure that the samples used had received as careful commercial processing as possible

The saponification and oxidation procedures used in the present work to prepare the samples for assay were examined as a source of isomerization Control experiments in which all-*trans* vitamin A palmitate was so processed produced negligible amounts of '*iso*' isomers, as measured by the infra-red procedure, and ruled out this possibility

The recognition of the prevalence of the *iso-a* and *iso-b* isomers made it of interest to isomerize samples of retinene *in vitro*, with dilute hydrochloric acid, until they had attained a state of 'equilibrium', defined as the point at which further exposure to acid produced no change in the proportion of the four isomers present Assays by the opsin and infra-red methods are reported in Table 2 As in fish liver oils, the proportion of combined *iso-a* and *iso-b* isomers in the vitamin A of the artificial iso-

Table 2

Sample No	Description*	Percentage *iso-a*+*iso-b* in total vitamin A isomers (opsin assay)	Percentage *iso-a*+*iso-b* in total vitamin A isomers (infra-red assay)
	Liver oil concentrates		
1	Shark 'non-sap' $E(1\%, 1\text{ cm})$ (328 mμ) = 538	24	—
2	Shark distilled 'non-sap' $E(1\%, 1\text{ cm})$ (328 mμ) = 628	26	—
3	Cod 'non-sap' $E(1\%, 1\text{ cm})$ (328 mμ) = 202	19	—
4	Distilled cod 'non-sap' E(373 mμ) = 427	25	—
5	Mixed fish liver oil 'non-sap' E(373 mμ) = 350	19	—
6	Rat liver oil† 'non-sap' E(370 mμ) = 270	14	—
	'Equilibrated' retinene isomer concentrates		
7	E(372 mμ) = 1,030	21	18
8	E(377 mμ) = 1,260	23	22
9	E(374 mμ) = 1,080	20	21

* The vitamin A in samples 1–6 was oxidized to retinene by manganese dioxide prior to assay

† Oil was a portion of that kindly supplied by Dr T K Murray, Food and Drug Directorate, Ottawa, Canada, for related bioassay studies

merates was about 20 per cent. The assays were run independently and the results indicated that with preparations of the purity investigated the two methods are in good agreement.

The average ratio of *iso-a* : *iso-b* isomers in the equilibrated samples was found to vary from about 2 : 1 to 4 : 1. This variability is probably caused, in part, by errors in measuring the relatively small amounts of *iso-b* isomer present.

Further information on the experimental methods is as follows.

Opsin. Opsin was prepared in digitonin solution, using a modification of the procedures described earlier[3,9,10]. This procedure will be reported in detail separately.

The essential steps in this procedure included dissection of retinæ from cattle eyes in the light, disintegration of the tissue by grinding, floating out the fragments of outer segments of the rods by differential centrifugation in phosphate buffer weighted with 40 per cent sucrose, lyophilization of the rod fragments, and exhaustive extraction of the dry powder with petroleum ether to remove extraneous lipids and vitamin A, and finally the extraction of opsin from the residue with 2 per cent aqueous digitonin. Such preparations were assayed for their opsin content with *neo-b* retinene (ref. 10). They were stored at about −15° C. until used for assay. They remained stable for many months.

Assay of retinene isomers. Samples of the mixed retinene isomers in a few drops of ethyl alcohol were pipetted into 2–3 ml. of 2 per cent digitonin in water. A cloudy solution usually resulted, depending on the concentration, but this was cleared by filtering through a fine sintered glass filter. The final solutions used for assay contained 5–10 μgm. of retinene.

Such solutions were assayed with opsin for their combined content of *iso-a* and *iso-b* isomers, as described for the assay of opsin itself, except that at least three times the equivalent amount of opsin was used in the determination. The photosensitive pigment formed in all experiments was *iso*rhodopsin (λ_{max} = 487 mμ), not rhodopsin.

Iso-a retinene combines directly with opsin to form *iso*rhodopsin. *Iso-b* retinene slowly isomerizes to *iso-a*, and hence forms the same pigment. With *iso-a* retinene, this synthesis is complete in 2 hr. at 23° C., whereas with *iso-b* retinene the same process is completed only within about 24 hr.

One therefore incubates an unknown mixture of retinene isomers with excess opsin, and measures the amount of *iso*rhodopsin formed at 23° C. in 2 hr., and in 24 hr. The amount formed in 2 hr. is primarily formed from *iso-a* retinene; that formed in 24 hr. measures the combined amounts of *iso-a* and *iso-b* retinene. A small correction of the 2-hr. value is needed to take care of the very small amount of *iso*rhodopsin formed from *iso-b* retinene during this period; the 24-hr. value is also corrected for the very small, almost negligible, synthesis of *iso*rhodopsin by the isomerization of all-*trans* and *neo-a* retinene during the incubation period.

Total retinene. The total amount of retinene in the samples was estimated by the antimony chloride reaction and recorded with a Cary recording spectrophotometer. The amount of retinene is determined on the basis that this blue product has *E*(1 per cent, 1 cm.) (664 mμ) = 3,740. From this and the preceding data, the percentage of combined *iso-a* and *iso-b* retinenes in the total retinene is computed.

Infra-red procedure. This work (by W. P. B.) was based on the curves for the individual retinene isomers already reported[5]. The percentage of combined *iso-a* and *iso-b* retinenes in the mixed retinene isomers is calculated from the absorption at 8.73μ, corrected for interference from the all-*trans* vitamin A and neovitamin A present by the absorption at 8.48μ.

The infra-red method has the advantage over the one employing opsin, that it can be used to determine the percentage of each of the four isomers in the sample, although we describe here only its use in determining the percentage of *iso-a* + *iso-b* isomers present. It has the disadvantage that the retinene content of the sample needs to be relatively high, at present, to minimize errors due to the absorption of impurities. We prefer a purity of about 75 per cent, *E*(1 per cent, 1 cm.) (370 mμ) = about 1,000, but procedures for concentrating preparations of lower purity are under study.

The equation employed in the Distillation Products Industries Laboratory is:

$$\text{Percentage } iso\text{-}a + iso\text{-}b \text{ in mixed isomers} = \frac{100\ k_a - (k_b + 0.01)}{k_c \times P}$$

where k_a = the extinction coefficient for the test sample at 8.73μ (1 per cent solution in carbon disulphide, 1 mm. cell, Perkin Elmer, Model 21, instrument, sodium chloride prism, slit programming No. = 9.75); k_b = the extinction coefficient at 8.48μ for the test sample; this value plus 0.01 is the 'background' correction determined with pure all-*trans* and neovitamin A aldehydes in a ratio (3 : 1) which approximates that present in the mixed isomer preparations studied; k_c = the extinction coefficient at 8.73μ for pure *iso-a* and *iso-b* retinenes in a ratio (3 : 1) which is approximately that present in the mixed isomer preparations studied; P = the concentration (per cent) of the total retinenes determined by the antimony trichloride reaction.

This work between the two laboratories was initiated and co-ordinated by Dr. J. G. Baxter, Distillation Products Industries, with the co-operation of Prof. G. Wald, Harvard University. Related bioassays and analytical studies by members of the Biochemistry, Vitamin Development and Organic Research Laboratories, Distillation Products Industries, were helpful in guiding the direction taken in the work. These bioassays and analyses will be reported separately.

LIVER GLUCOSYL OLIGOSACCHARIDES AND GLYCOGEN; CARBON-14 DIOXIDE EXPERIMENTS WITH HYDROCORTISONE

By Dr. HSIEN-GIEH SIE, Prof. JAMES ASHMORE*, Dr. ROBERT MAHLER† and
Prof. WILLIAM H. FISHMAN

Tufts University School of Medicine and the New England Center Hospital, and
Harvard Medical School, Boston, Mass.

IT has not been possible for geographical reasons to continue a collaborative study designed to clarify, through the use of carbon-14 dioxide, the biochemical significance of liver glucosyl oligosaccharides, particularly in relation to the action of adrenal corticoid hormones. We therefore wish to report our findings to date.

Sie and Fishman[1] observed earlier that hepatic glucosyl oligosaccharides fluctuated in the same direction as did liver glycogen in starvation, glucose feeding and insulin administration. Under these conditions, our concern lay with the dynamics of the glucose unit, either produced from glycogen, as in starvation or in insulin administration, or exogenously provided in the glucose feeding experiment. On the other hand, liver glycogen resulting from the action of hydrocortisone in fasted rats[2] is considered to originate from the catabolism of protein. Since hexose synthesis from pyruvate and lactate is believed to require carbon dioxide fixation[3], hepatic gluconeogenesis could be followed with carbon-14 dioxide without supplying an exogenous substrate or preformed glucose units. The following experiments have been carried out.

In the first series of experiments, male Wistar rats (150–175 gm.), after 22–24 hr. of fasting, were injected with 50 μc. of carbon-14 dioxide bicarbonate (isotonic saline, intraperitoneally) 1 hr. before killing, and at 3 hr. and 5 hr. after hydrocortisone (5 mgm./animal in saline microcrystalline suspension) was injected by the same route (Fig. 1). In the second series of experiments, 50 μc. of radioactive bicarbonate was injected 3 hr. after an initial injection of 5 mgm. of hydrocortisone. Animals were killed afterwards at intervals up to 3 hr. (Fig. 2).

At the times indicated, the experimental animals were killed by decapitation, and the livers rapidly removed and frozen in a dry ice bath. A 10 per cent homogenate of each liver was prepared with ice-cold water, keeping the homogenizer packed in ice. This mixture was deproteinized by additions of 10 ml. of 5 per cent zinc sulphate and 10 ml. of 0·3 N sodium hydroxide solution. After centrifugation, the precipitate was washed twice with 10 ml. of cold distilled water, and the washings and supernatant solution were pooled. The oligosaccharides were adsorbed from this mixture with charcoal, which was then washed with copious amounts of distilled water, and eluted afterwards with hot ethanol[1]. Total glycogen was isolated by Roe's method[4]. Glycogen and oligosaccharides were hydrolysed with hot mineral acid[5], and the glucose was estimated by the Nelson method[6]. Tail vein blood was obtained for the determination of carbon dioxide and glucose[7]. The quantity of carbon dioxide in the blood was determined in the Van Slyke apparatus and was recovered and counted as barium carbonate. Glucose was isolated as phenylosazone[8], which was recrystallized, plated and counted. A Robinson flow counter was used for the radioisotope assays[9].

The following observations are made. Animals whose liver glycogen had been almost completely depleted by fasting not only possessed a significant amount of glucosyl oligosaccharides, but also they exhibited about four times the specific radioactivity found in the glycogen and contained virtually all the labelled hexose. With the stimulation of gluconeogenesis by compound F, the specific activity of the glucosyl oligosaccharides diminished, while that of glycogen increased at the 4 hr. interval. In Fig. 2, where it is possible to follow all the events as a function of time after compound F and carbon-14 dioxide administration at the times indicated, it required about 1 hr. for the carbohydrates to incorporate the maximum level of carbon-14. In the early part of this process (between 3·25–3·5 hr. after compound F) the glucosyl oligosaccharides became more richly labelled than

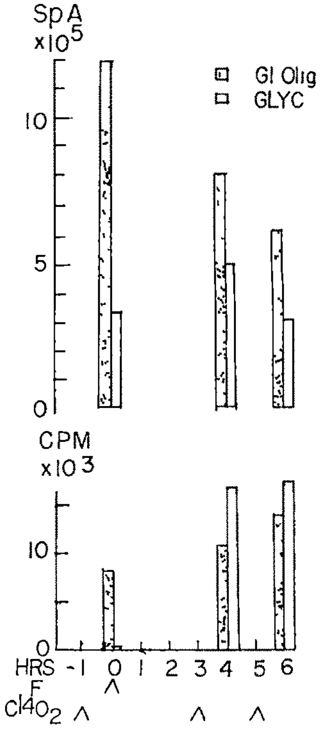

Fig. 1. Carbon-14 labelling of liver glucosyl oligosaccharides and glycogen in relation to the administration of compound F. Note that the animals were killed in each instance 1 hr. after the injection of carbon-14 dioxide. The numbers of rats employed for each time interval were, respectively: –1 to 0, 2; 0 to 4, 4; 0 to 6, 2

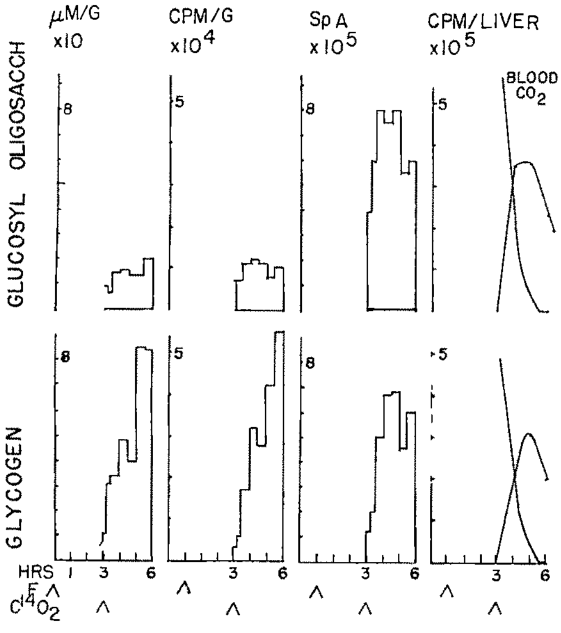

Fig 2 Carbon-14 turnover in liver glucosyl oligosaccharides, glycogen and blood carbon dioxide in relation to compound *F* administration The number of animals used was two at each time interval except for the 4-hr column (4 rats) The relative specific activity of blood carbon dioxide was computed on the assumption that carbon-14 dioxide was incorporated into only carbons 3 and 4 of glucose The observed c p m /mole of barium carbonate have been divided by three, and the same plot (descending curve) appears for both glucosyl oligosaccharides and glycogen

the glycogen by a factor of 3 and for another 2 hr still remained more radioactive per milligram of polysaccharide glucose This situation is reflected in the curves relating total counts per liver of each carbohydrate category against a background of rapid carbon-14 dioxide disappearance from the blood After 3 5 hr the glucosyl oligosaccharides exhibited a constant number of counts per gm of liver, whereas those for glycogen continued to rise to the end of the period investigated (6 hr) However, for this interval, specific activity of glycogen paralleled that for the glucosyl oligosaccharides In general, carbon dioxide fixation matched carbohydrate synthesis following the injection of hydrocortisone

The interpretation which appears best to fit the above facts is the following Pyruvate and lactate (since these fix carbon dioxide during their conversion to glycogen) are probably the major protein-supplied precursors of glucosyl radicals in fasted rats treated with hydrocortisone These glucosyl radicals are first linked into individual members of a homologous family of glucosyl oligosaccharides (maltose, maltotriose, maltotetraose, etc) which is 'turning over' rapidly Under the proper physiological stimulus (glucose feeding, compound *F*) these oligosaccharides are assembled into macro-molecules of glycogen

In our previous work, first consideration was given to isolating, identifying, characterizing and determining quantitatively liver glucosyl oligosaccharides[10], and the next concern was to rule out the possibility of artefact due to the operation of extraneous factors of either a biochemical or physical nature[1,10] Our attention was directed recently to the question of the origin of glucosyl oligosaccharides and their possible significance in the metabolism of liver glycogen The implication of previous experiments[1] (starvation, glucose feeding, insulin administration) and the work of others[11] with rat diaphragm was that glucosyl oligosaccharides (no matter what their origin) may enter somewhere into the mechanism of glycogen synthesis The present results supply direct evidence in support of this suggestion

RELEASE OF NUCLEOTIDES FROM YEAST CELLS

By MASATAKA HIGUCHI and PROF TEIJIRO UEMURA
Laboratory of Microbiology, Department of Agriculture, Tohoku University,
Sendai, Japan

IT is well known that when *Lactobacilli* are cultured in association with yeast, the former organisms are able to proliferate in a simple medium containing no growth factors specific for them The resulting growth of *Lactobacilli* is mainly dependent on vitamins, purine and pyrimidine bases secreted by the yeast cells into the medium[1,2] The present communication contains a description of the ultra-violet-absorbing materials released from the yeast cells and the conditions influencing their release

Beer yeast (*Saccharomyces cerevisiae*, Yebis) subcultured for 72 hr at 30° C in a synthetic medium was incubated for 5 hr at 30° C in the same medium containing phosphate-^{32}P After harvesting and washing three times with distilled water, the labelled cells (dry weight, 1,760 mgm) were suspended in 400 ml of 0 08 *M* sodium citrate buffer (*p*H 6 0) with 2 per cent glucose added, and incubated for 3 hr at 30° C The supernatants after incubation had an ultra-violet absorption spectrum with a maximum at 258 mμ and a minimum at 235 or 240 mμ

The ultra-violet-absorbing materials released from the cells were almost completely adsorbed by a charcoal column pretreated with 8 per cent *iso*octanol

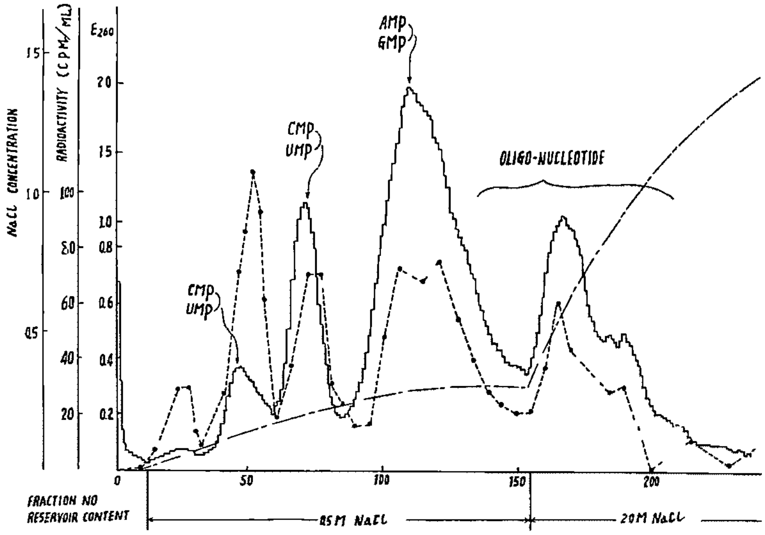

Fig 1 Separation of the nucleotides released from yeast cells labelled with phosphorus-32 during their incubation in citrate buffer Column, 'Dowex-2' (chloride), 200–400 mesh, 12 cm × 0 785 cm², elution, the initial mixer content was 500 ml water, and the reservoir content was 500 ml of 0 5 *M* sodium chloride, then 500 ml of 2 0 *M* sodium chloride solution Each effluent was collected in 4 7 ml portions with a fraction collector Sorbed materials, the ultra-violet-absorbing materials prepared as described in text ———, Optical density at 260 mμ, – – – –, radioactivity (c p m /ml), —·—·—, sodium chloride concentration in the effluents CMP, Cytidine monophosphate, UMP, uridine monophosphate, AMP, adenosine monophosphate, GMP, guanosine monophosphate

More than 80 per cent of the adsorbed material was eluted with 0 3 per cent ammonia–50 per cent ethanol solution The eluate from the charcoal was neutralized with 'Dowex 50' (acid type) resin, and then passed through 'Dowex 2' (chloride type) resin The adsorption in this step was more than 90 per cent The column was washed with water, and the adsorbed material was separated with a sodium chloride solution by the gradient elution technique[3] The optical density at 260 mμ and 280 mμ and the radioactivity of each effluent were measured

The results for six fractions are shown in Fig 1 The positions, but not the heights, of optical density peaks agree well with those of radioactivity The initial fractions (eluted with less than 0 3 *M* sodium chloride solutions) were rechromatographed on 'Dowex 1' (formate type) and then on paper, the monophosphates of cytidine, uridine, adenosine and guanosine were identified in this way The oligonucleotide fractions (eluted with 0 3–1 5 *M* sodium chloride) followed the mononucleotides The recovery using sodium chloride solution, even up to 4 0 *M*, was only about 60 per cent of the calculated amount of adsorbed material However, when a mixture of 4 0 *M* sodium chloride and 1 0 *M* sodium hydroxide solutions was used as eluant, the residual material was almost completely separated from the column This alkali-eluted fraction, the final eluate, contained four mononucleotides, which would presumably be derived from polynucleotides hydrolysed by alkali during the elution Details of this chromatogram will be published elsewhere

Oligo- and poly-nucleotides formed more than 60 per cent of the total nucleotides released, and the ratio of purine bases to pyrimidine ones in the mononucleotide fractions was 2 5, though it was 1 2 overall These ratios depended on the experimental conditions Most of the nucleotides released were probably fragments of the cellular ribonucleic acid, since scarcely any 5′-nucleotides were in any fraction, and amounts of the nucleotides released corresponded approximately to the decrease of cellular ribonucleic acid Moreover, the quantity of nucleotide released was greater than that in the pool (fraction soluble in cold acid) which decreased during incubation

As shown in Table 1, distilled water, sodium chloride and potassium chloride solutions and a synthetic growth medium did not cause a release of nucleotides when used as the incubation medium, acetate or succinate buffers had a slight effect and phosphate or citrate buffers rather more effect This stimulation of citrate or phosphate might be well attributed to their chelating action, since ethylene-diamine tetraacetic acid, a notable chelating agent, markedly accelerated the nucleotide release, and the addition of *M*/100 magnesium sulphate to *M*/50 citrate buffer resulted in a 50 per cent reduction of the release

Inhibition of the release in citrate buffer was not observable in the presence of either ordinary antibiotics (penicillin, 20 μgm /ml, streptomycin, 300 μgm /ml, and chloramphenicol, 20 μgm /ml) or of metabolic inhibitors (sodium azide, 10^{-3} *M*, Na_2HAsO_4, 2×10^{-2}, and 2,4-dinitrophenol, 5×10^{-4} *M*), except monoiodo-acetic acid which produced a slight drop at 10^{-3} *M* The *p*H optimum for the release in citrate or phosphate buffer was 6 0–7 0 and an acid *p*H suppressed the release Several treatments which disrupt the permeability barrier of yeast cells, for example, freezing and thawing, treatment with organic solvents, and short-time sonication of the cells, stimulated the release considerably After such treatment an enhancing effect of citrate was also discernible However, it is possible that the materials released in these conditions are not the same as the nucleotides released by the intact cells, since the supernatant of the citrate buffer incubated with sonicated or frozen and thawed cells showed an increased absorption at 230–250 mμ, which disappeared on acidification with perchloric acid

Recently, a similar phenomenon has been reported by Holden[4] for *Lactobacilli* His results, and ours[13],

Table 1 EFFECT OF INCUBATION MEDIUM ON THE RELEASE OF NUCLEOTIDES FROM THE YEAST CELLS

All results are expressed in terms of 100 mgm (dry weight) of the cells

Incubation medium	Released nucleotide-phosphorus (μgm)
Distilled water	46 5
0 08 *M* sodium chloride solution	33 0
0 08 *M* potassium chloride solution	34 5
0 08 *M* sodium acetate buffer (*p*H 5 0)	65 0
0 08 *M* sodium succinate buffer (*p*H 5 0)	62 0
0 08 *M* sodium phosphate buffer (*p*H 5 0)	80 5
0 08 *M* sodium citrate buffer (*p*H 5 0)	115 0
M/100 Ethylenediamine tetraacetate (*p*H 4 2) solution	68 0
M/100 Ethylenediamine tetraacetate (*p*H 5 0) solution	102 0
Synthetic growth medium	45 0

Beer yeast cultured in a synthetic medium for 72 hr at 30° C was incubated in 10 ml of medium containing 2 per cent glucose for 3 hr at 30° C The released nucleotide-phosphorus was determined as follows The extinctions in the supernatant of the incubated media were measured at 240, 260 (E_{260}) and 280 mμ respectively, with a Beckman *DU* spectrophotometer, and the E_{260} due to the released nucleotides was obtained by subtracting the blank (the medium free from cells) from the E_{260} of the supernatant Thus, the nucleotide-phosphorus could be calculated according to Ogur and Rosen (ref 12) strongly suggest that citrate has a chelating effect which affects the release of nucleotides from the microbial cells.

On the basis of these results, it might be suggested that the presence of citrate or other chelating substances in a medium may remove calcium or magnesium ions from the cell surface, leading to destruction of ribonucleic acid and present in it, and thus to a release of nucleotide fragments. Several facts support this. For example, pancreatic ribonuclease is inhibited by the addition of magnesium or calcium ions[5], and a ribonucleic acid-rich fraction obtained from the cells of *E. coli* contains more magnesium than other fractions[6]. Further, ribonucleoprotein has apparent[7,8] or latent[9] ribonuclease activity.

On the other hand, it has often been observed that the degradation of ribonucleic acid and the release of ribonucleate from yeast cells takes place by autolysis[10,11]. The release of nucleotides under our experimental conditions may also be connected with cell autolysis. However, it seems reasonable to distinguish between the two, since the release in our case did not result in the death of the cells or even in degradation of the cell protein. In contrast, a considerable release of amino-acids occurred only when the yeast cells were incubated in the acetate buffer, which accelerated release of nucleotide only slightly.

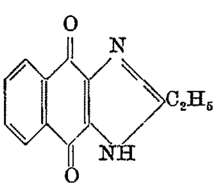
NEW ANTIMETABOLITES OF VITAMIN B_{12}

By G. M. TIMMIS and DR. S. S. EPSTEIN

Chester Beatty Research Institute, Fulham Road, London, S.W.3, and
The Hospital for Sick Children, Great Ormond Street, London, W.C.1

OUR interest in the role of vitamin B_{12} in cancer was first stimulated by the claims of Bodian[1], that prolonged regression of neuroblastoma in infancy was effected by massive dosage of the vitamin. It was therefore thought that the therapeutic effect claimed might be related to an imbalance in B_{12} metabolism caused by excess of the vitamin, and that such an effect might possibly be better produced by the administration of a B_{12} antimetabolite[2].

Hitherto, the only known B_{12} antimetabolites have been those described by Lester Smith[3], which were derived from the structure of B_{12} by very minor modifications, and also those which are relatively simple derivatives of the benzimidazole molecule[4,5]. The relation between tumour inhibition and anti-B_{12} action is shown in a member of the latter group by the effect of 2-ethyl-2,3-naphthimidazole-4,9-dione (I), which induced partial regression of a mouse mammary adenocarcinoma[6] and was also a competitive antagonist of vitamin B_{12} in an *E. coli* mutant[4].



(I)

We have explored a fairly wide variety of chemical types, chosen for their possible relation to B_{12} metabolism, for an antimetabolite action in a microbiological system. Our particular test organism was *E. gracilis* var. *z*—a highly sensitive B_{12}-dependent flagellated green alga. The basal growth medium and techniques of incubation were based on those described by Hutner *et al.*[7]

A series of approximately a hundred compounds was screened for inhibitory activity at 500 μgm./ml. levels, at low concentrations of vitamin B_{12}. Compounds producing more than 50 per cent inhibition of growth, as assessed in a colorimeter (measuring both turbidity and colour), were afterwards re-tested in definitive assays. An orthogonally designed test system was used, with varying concentrations of antagonist up to 500 μgm./ml. in the presence of 0, 10, 100 and 1,000 μμgm. B_{12}/ml. The growth response in these tests was measured by a pigment extraction technique using an acetone–ethyl acetate solvent system due to Epstein and Weiss[8].

Results are expressed in terms of concentration of antagonist required to produce 50 per cent inhibition of growth at 10,100 and 1,000 μμgm. B_{12}/ml. respectively. The values given are only approximate. As can be seen from Table 1, seven out of the fifteen compounds so far found active on screening produced a competitive B_{12} antagonism.

We think that the discovery of an antimetabolite action in the pteridine and nicotinamide structures is interesting because, unlike the benzimidazoles or purines, they are not analogous in structure to any moiety of the B_{12} molecule. These observations indicate that there may be a variety of enzymes or co-factors closely concerned with the utilization of B_{12}, and that each one may be structurally specific for a particular inhibitor. Thus, the pteridines might compete with a pteridine type co-factor or metabolite for a particular enzyme, and the nicotinamide derivatives might interfere with some function of diphosphopyridine nucleotide (cf. Timmis[9]).

Table 1 CONCENTRATIONS OF ANTAGONISTS (μGM /ML) PRODUCING 50 PER CENT INHIBITION OF GROWTH OF *E gracilis*
Results in the case of compounds producing competitive antagonism are given in italics

Structures of compounds tested, (*a*), (*b*) , are on the right

Structural type	Formula	Concentration antagonist (μgm / ml) required to produce 50 per cent inhibition of growth		
		B_{12} (μμgm /ml) 10	100	1,000
(*a*) Benz-imidazoles	4-nitro-6-chlorobenzimidazole ($R^1 = NO_2$, $R^2 = H$, $R^3 = Cl$, $R^4 = H$)	110	88	78
	5,6-dichlorobenzimidazole ($R^1 = R^4 = H$, $R^2 = R^3 = Cl$)	106	90	94
	4,5,6-trichlorobenzimidazole ($R^1 = R^2 = R^3 = Cl$, $R^4 = H$)	70	65	63
	4,5,6-trichlorobenzimidazole riboside ($R^1 = R^2 = R^3 = Cl$, R^4 = ribosyl)	*70*	*160*	*230*
(*b*) Diaza-benz-imidazole	5-bromo-2,7-diazabenz-imidazole	190	178	173
(*c*) Purines and aza-purines	Purine ($R^1 = R^2 = H$, $X = CH$)	138	173	138
	Purine riboside ($R^1 = H$, R^2 = ribosyl, $X = CH$)	58	62	60
	6-mercaptopurine ($R^1 = SH$, $R^2 = H$, $X = CH$)	*200*	*>500*	*>500*
	9-furfuryl-8-aza adenine ($R^1 = NH_2$, R^2 = furfuryl, $X = N$)	*450*	*>500*	*>500*
	2-diethylamino-6-*p*-dimethyl-aminophenylethyl purine ($R^1 = (CH_2)_2C_6H_4N(CH_3)_2(p)$)	*150*	*>500*	*>500*
(*d*) Pyrimidine	5-fluorouracil	78	55	54
(*e*) Pteridines	4-mercaptopteridine ($R^1 = SH$, $R^2 = H$)	*95*	*350*	*333*
	2-amino-4-*p*-diethylamino-styrylpteridine ($R^1 = (CH)_2\,C_6H_4\,N(C_2H_5)_2\,(p)$, $R^2 = NH_2$)	*73*	*>500*	*>500*
	4-dimethylaminopteridine ($R^1 = N(CH_3)_2$, $R^2 = H$)	*400*	*>500*	*>500*
(*f*) Nicotin-amide de-rivative	N-2-chloroethyl-β-naphthyl-aminoethyl-3-carbamoyl-pyridinium chloride	*200*	*430*	*415*

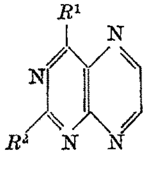
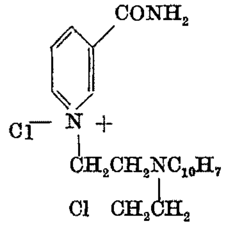
(*d*)



(*e*)



(*f*)

There are interesting differences between the results obtained in our microbiological system and in the *E coli* mutant used by McNair Scott *et al* [5], for example, 6-chloro-4 nitrobenzimidazole was not a competitive antagonist in our hands, in contrast to 4,5,6-trichlorobenzimidazole riboside On the other hand, McNair Scott *et al* [5] found these compounds to be competitive and non-competitive antagonists respectively

It is generally held that 6-mercaptopurine, one of the most effective drugs for the treatment of acute leukæmia, inhibits growth by interfering with nucleic acid and protein synthesis. Its action in this disease, however, has not with any certainty been related to an antipurine effect Since we have found that this drug is a competitive B_{12} antagonist (Table 1), we would like to direct attention to the possibility that anti-B_{12} effect might be involved in the action of 6-mercaptopurine This speculative suggestion could be supported by the view of Osgood[10] that the bone marrow in untreated pernicious anæmia shows several features in common with that in acute leukæmia If the two diseases are accordingly related, acute leukæmia may, like pernicious anæmia, be dependent on some derangement of B_{12} metabolism, each in its own way

Forrest *et al* [11] have very recently isolated a simple pteridine from the bodies of blue-green algae It is shown above that a number of pteridines of comparable simplicity are vitamin B_{12} antimetabolites in the B_{12}-dependent system *Euglena gracilis* On reading our manuscript, Dr G E Fogg suggested that the apparent inability of blue-green algae and Euglenidae to co-exist in Nature, a hitherto unexplained phenomenon, may be due to an antagonism between the blue-green algae pteridine and the vitamin B_{12} of B_{12}-requiring *Euglena* We are now investigating this hypothesis

A full report of this work will shortly be submitted to the *British Journal of Pharmacology and Chemotherapy*

The investigation has been supported by grants from the British Empire Cancer Campaign, the Jane Coffin Childs Memorial Fund for Medical Research, the Anna Fuller Fund and the National Cancer Institute of the National Institutes of Health, U S Public Health Service

We thank Dr G B Brown and Dr K Folkers for gifts of purine riboside and 4,5,6-trichlorobenzimidazole riboside respectively

LOW-TEMPERATURE AUTORADIOGRAPHY FOR THE DETECTION OF TRITIUM IN TISSUE, WITH REMOVAL OF LUMINESCENCE INDUCED BY TRITIUM

By P PELLERIN, P FALLOT, M LAINE-BOSZORMENYI* and F SERREL

Service de Biologie du Commissariat à l'Energie Atomique, B P 2 Gif sur Yvette (S et O), France

NUMEROUS studies have shown inequalities in the distribution of labelled water in the different organs and various compartments containing liquid in the normal animal[1,2] during the pre-equilibrium period

It seemed of interest to investigate by means of photographic recordings the kinetics of this distribution, working on animals (young rats) killed at fixed intervals of time For that purpose we used the low-temperature autoradiographic technique[3,4], the only method which, because of the rapid freezing of the animal, eliminates post-mortem diffusion of the water while at the same time guaranteeing the absence of known pseudo-radiographic effects

We wished first to obtain an image of homogeneous diffusion in the whole of the organism, under conditions close to equilibrium, and this formed the object of the present work

The photographic recordings obtained by this technique, applied to young rats after administration of 20 mc of tritiated water, gave unexpected results (Fig 1*a*) They show no blackening corresponding to lungs, liver, spleen, muscle On the other hand, a slight darkening shows up in the region of the intestinal walls and the subcutaneous tissue, and a very intense blackening at the sites of the eye, the brain, the preformed teeth, the stomach, the bladder and the intervertebral disks

Since these results disagreed with the known distribution of water in mammals, we removed organs from young rats treated in the same way except that the dose injected was between 0 4 and 1 5 mc of tritiated water (HTO) in a volume of 0 1–0 2 ml of saline The radioactivity of the water obtained by distillation of the organs was measured by liquid scintillation[5,6]

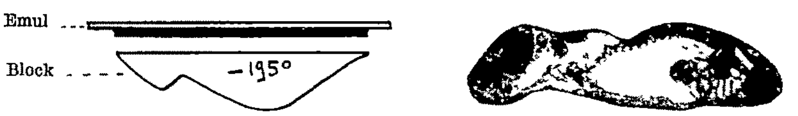
It is shown in Table 1 that the specific radioactivity of the water (mμc /mgm) is of the same order for the blood and for organs such as the brain, the liver and spleen, the kidneys and the intestines On the other hand, the milk in the stomach has not yet reached the isotopic concentration of HTO in the other organs The specific radioactivity of the water in the total eye, the crystalline lens and the ocular residue after elimination of the crystalline lens is more or less identical with that of the blood We have also noted that for the eye the radioactivity was entirely due to the water, and that no measurable tritium was incorporated in the dry residue

Table 1 SPECIFIC RADIOACTIVITY OF WATER IN THE ORGANS OF YOUNG RATS WEIGHING 14–20 GM , AGED 6–14 DAYS, 10 MIN AFTER SUBCUTANEOUS OR INTRAPERITONEAL INJECTION OF 0 1–0 2 ML OF SALINE CONTAINING 0 4–1 5 MC TRITIATED WATER, STANDARD DEVIATION ± 2 PER CENT

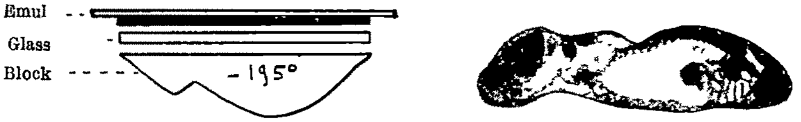
Organ	Millimicrocuries of HTO per mgm water				
	Rat 21	Rat 23	Rat 15	Rat 19	Rat 20
Blood	—	44	88	80	80
Brain	44	43	90	92	75
Liver, spleen	45	—	—	88	90
Liver, spleen, kidneys	—	46	85	—	—
Bowel, small and large, with contents	48	45	80	92	91
Stomach containing milk	—	—	41	37	46
1 eye*	40	36	—	88	—
1 crystalline lens*	46	—	—	85	40
1 eye without crystalline lens*	42	—	—	90	—

* The water content is calculated on the basis of 70 per cent of water for the crystalline lens and 80 per cent for the rest of the eyeball

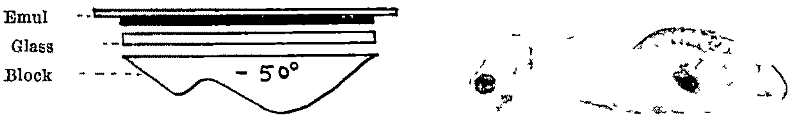
In view of the disagreements found between the photographic recordings and direct measurements, we have looked into the mechanism of autoradiography itself in an attempt to find the cause of these paradoxical images , this has led to the discovery of a phenomenon of luminescence produced at low temperature under the influence of the very soft tritium beta-rays, actually within certain tissues of the organisms studied



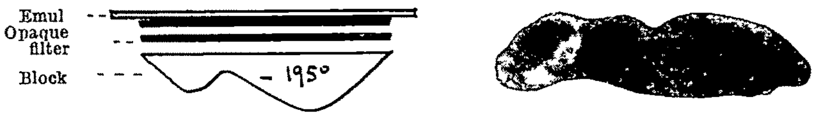
(*a*) 20 min at −195° C No filter



(*b*) 20 min at −195° C With glass filter



(*c*) 20 min at −50° C With glass filter



(*d*) 21 days at −195° C With opaque screen

Fig 1 Two-day-old rat Subcutaneous dorsal injection of 20 mc deuterium oxide 20 min after injection

---

* Attachée de Recherche à l'Institut National d'Hygiene

This is demonstrated by the following series of experiments (Fig 1) carried out on rats 48-hr old, killed 20 min after dorsal-subcutaneous injection of 20 mc of tritiated water

(1) (See Fig 1*a*) The machined block at −195° C is applied directly against the emulsion The exposure lasts 20 min at liquid-nitrogen temperature In this way the paradoxical image described above is obtained

(2) (See Fig 1*b*) Exposure of the same block at the same temperature for an equal period, but with a 1-mm thick sheet of glass interposed, gives an image identical with the preceding one Since, however, the maximum energy of tritium beta-particles (18 keV) is not great enough to allow their passage through this thickness of glass, the image obtained is not due to a direct action of tritium radiation on the emulsion and can only result from a luminescence

(3) (See Fig 1*c*) On repeating experiment *b* at a temperature of −50° C., a general decrease in blackening is noted, although the distribution is not altered

(4) (Fig 1*d*) Finally, exposure for 21 days at −195° C with a screen of opaque carbon paper interposed between the block and the emulsion gives a true autoradiographic recording on which quite a homogeneous distribution of blackening is observed

From this limited study, some characteristics of this luminescence produced by the local absorption of tritium beta-radiation by certain tissues can be formulated It becomes more intense as the temperature is lowered For a uniform distribution of tritiated water in the organism, the intensity of this fluorescence varies greatly according to the nature of the tissue

For the exposure time used, the threshold of blackening detectable on the emulsion for tritium beta-radiation is not reached at any point of the recording, while the phenomenon of luminescence reaches saturation in the region of the eye, as shown in Fig 1*a* When a screen opaque to light is interposed (Fig 1*d*) the exposure time to obtain an appreciable blackening is 1,600 times longer than in the case of exposure without screen (Fig 1*a*) It may seem surprising that part of the tritium beta-radiation (mean path in water, 1μ) can pass through a thickness of paper of the order of 50μ We believe that the explanation may be found in the fibrous structure of the paper

We may assume that the autoradiographic recordings obtained under the conditions of experiment *d* (with opaque screen) represent exactly the distribution of tritium at the surface of the machined block

After dorsal subcutaneous injection of tritiated water, the autoradiographs show instantly homogeneous diffusion of the activity, the only exceptions being the bones, the teeth and the milk contained in the stomach The teeth and the milk, however, form exceptionally luminescent zones The region of dorsal injection naturally corresponds to a more intense blackening

The detailed mechanism of this luminescence is difficult to interpret and belongs to the field of structural physics We do not, in fact, know the chemical nature of the luminescent substances present in the frozen organs, still less their molecular structure at −195° C, or their behaviour in the presence of beta-radiation

Validity of low-temperature autoradiography The above statements could lead to some doubt concerning the value of recordings obtained by low-temperature autoradiography with radioelements other than tritium[3,4] We have verified that this is not the case, in particular with sulphur-35 and calcium-45 Fig 2*a* shows the result of autoradiography without screen carried out on a young rat, 90 min after dorsal subcutaneous injection of 30 μc of calcium-45 chloride, with a 17-hr exposure In Fig 2*b* the interposition of a glass screen eliminates all recording for this exposure period (except for the left fore part of the head which was not covered by the glass sheet), the luminescence effect, therefore, does not appear under these conditions for calcium-45 radiation

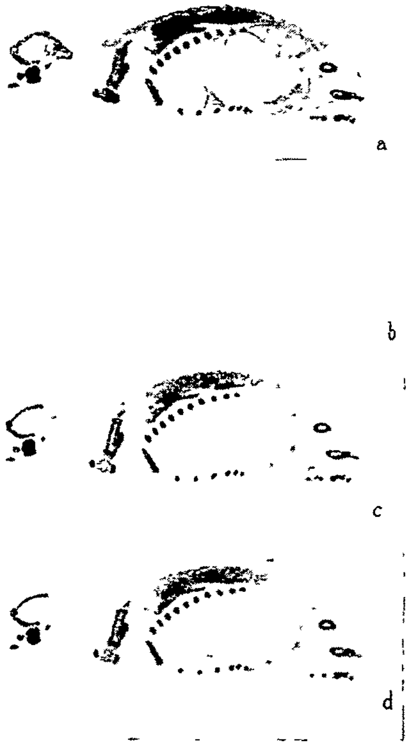


Fig 2

The recording in Fig 2*c* and *d*, carried out after interposition of a carbon paper screen and of an aluminium screen 0 2 mm thick, respectively, can be strictly superimposed on the direct autoradiograph *a*, with the difference only of general blackening, which is slightly decreased by the screens used for *c* and *d*

In tests carried out under the same conditions of metabolism and exposure after injection of 50 μc of sulphur-35, by direct contact and with interposition of a carbon paper screen, an absence of luminescence was again observed

We conclude that the luminescence effect of tissues at very low temperature is only detectable for extremely soft radiations such as that of tritium. It is advisable, however, in applying autoradiography at very low temperature to other radio elements, to verify that the interposition of an opaque filter does not modify the images obtained by direct contact between the block and the emulsion

A ZOOLOGICAL SURVEY OF MADAGASCAR

By Dr. RENAUD PAULIAN

Directeur-adjoint de l'Institut Scientifique de Madagascar

THE survey of tropical faunas has, for nearly two centuries, been largely limited to the haphazard methods of the general collector or to the painstaking but limited efforts of individual specialists. The results, as could be predicted, were of very doubtful value when either ecological or biogeographical projects were considered. However, they were extraordinarily successful in so far as they brought to light a very large number of new forms and built up our present knowledge of taxonomy. It unfortunately proved impossible to compare, with any accuracy, the faunas of two neighbouring areas for any scientific purpose. This did not prevent ambitious workers from building biogeographical or ecological systems on a very large scale. Yet to the man working in the field these systems seemed always rather unsafe, even though they called in all the resources of the geological and statistical methods and very strict logical constructions.

As a tropical country, Madagascar had for some time the very rare distinction that a series of monographs in the *Histoire Physique, naturelle et politique de Madagascar* had been published by the combined efforts of A. and G. Grandidier. It could thus compare with Central America, Seychelles, Hawaii or British India. But even these monographs, mainly published during the second half of last century, are now considered out of date.

In the years following the Second World War, research work on tropical faunas has started on completely revolutionary lines. New research institutions and groups are either working permanently in tropical areas or covering these in terms of long-range work. They are thus enabled to collect intensively the whole year round, using breeding methods and many new collecting systems. Such teams are at work in the Belgian Congo, Micronesia, Melanesia, etc.

The Zoological Survey started in Madagascar in 1947 and is still at work. It would seem from published results[1] that it has been particularly successful. It is centred on the Zoology Department of the Institut Scientifique de Madagascar, an institution covering pure and applied research in most fields of human, animal and plant biology and in soil science, hydrology and geography. The Institute itself belongs to a chain of tropical institutes created after 1946 by the French Office de la Recherche Scientifique et Technique Outre-Mer in what was then the French Union and is now the French Community.

It may be of interest, considering the variety of results obtained in the short period 1947–59, to give some details on the practical organization of the Survey before describing the changes wrought in our knowledge of the local fauna.

Considering that only limited means could be brought to bear on the problem of such a survey, the following principles have been applied:

(*a*) The formation of a mobile team with one or two European scientists, a number (3–6) of native assistants, a 'Landrover', and all the basic collecting equipment. This team has the use of a small permanent workshop in the centre at Tananarive for the building of new gadgets, and the constant upkeep of the material used.

(*b*) A central office, with one to three European scientists and three or four native assistants, which receives the collections, prints the labels, mounts and sorts the material and makes a preliminary study of all collections. More breeding work is carried on in the insectarium of the Central Office.

(*c*) A very large team of honorary research workers, specialists of international reputation, from practically every country of the world. They have agreed to work out collections made in Madagascar from their special groups. They are responsible for describing any new or remarkable forms and preparing revisions of such families, tribes or genera which may be considered as fairly well known. More than a hundred specialists have been enlisted in this way.

(*d*) A practical organization enlisting the co-operation of well-known foreign specialists, giving them all possible help and practical local guidance, helping them with the necessary camping and collecting outfit, etc. This organization can help specialists who come to Madagascar on their own, arrange for joint expeditions, or even finance complete expeditions, to which they are invited. In this way, during the past ten years, no less than thirty-three zoologists have taken part in the survey and some of them have spent more than a year in Madagascar or have come several times. The 'geographical distribution' of these specialists is worth noting: two Mauritians, five South Africans, one Rhodesian, two East Africans, three Swiss, three Austrians, three Italians, one German, eight Americans, one Australian and five French. In all cases the material collected or the observations made are embodied in the general publications of the Institute.

(*e*) Means for regular and so far as possible prompt publication of results. These have been obtained by the channel of two new scientific periodicals: papers on the local fauna make up the whole of the *Mémoires de l'Institut Scientifique de Madagascar*, Series A (zoology) and E (entomology), and are the main topic in the *Naturaliste malgache*. Whenever a group seemed sufficiently well known, a revision is published in the series "Faune de Madagascar", on the plan of the well-known "Faune de France". Apart from the nine published volumes of this series, three other volumes are ready to be printed and half a dozen others (covering such groups as birds, Acridoidea, Vespidae, Tingidae) are being actively prepared.

It was planned at the start to limit the survey to Madagascar proper. However, it was soon found necessary to cover the insular environment, the Mascarenes, the Comoros and the small atolls or coral reefs (Tromelin, Europa, Glorioso). Although the knowledge we may gain of their fauna is completely independent of Madagascar proper, it is a great help towards an understanding of the malagasy fauna itself.

It is still too early to give a complete analysis of the results of the Survey. More than a million specimens have been collected, covering the whole animal kingdom from protozoa to mammals, and a very large part of this material is still undergoing systematic study.

From the purely taxonomical side more than 2 500 new forms (subfamilies, tribes, genera and species) have been described. Many orders have been discovered on Madagascar proper (for example, fresh-water Coelenterata, Porifera, Bryozoa, in Insecta Zoraptera, Plecoptera, Diploura, Protoura, in Chelicerata Palpigrada, Uropyga, Amblypyga, in Crustacea Syncarida) and many more groups. No animal group has remained untouched, and often the known number of forms has risen by as much as 500 per cent.

The very great variety of new forms found in the island has completely changed its aspect and helped to build an entirely new system of biogeographical relations.

The Survey has opened up a number of new biota: many new groups of cave-dwelling forms have been detected, such as scorpions and Homoptera, that were not known previously from this habitat, a very large and highly specialized blind soil-fauna, probably one of the richest in the world, a series of crustaceans and worms inhabiting interstitial waters, both salt and fresh, an original intertidal fauna of land arthropods, a rich fauna living in the water found in leaf axils of palms, Musaceae, Aroideae and in bamboos. This last fauna is exceptionally large and its members range from frogs to insects and crustaceans, mosquitoes play a very important part, with high speciation and remarkable morphological adaptations.

Less original, but quite as important results have been obtained by the systematic breeding of parasites (chalcidoids, tachinids, etc.) and of leaf-mining and gall-making insects. These researches have brought to light new biological facts for known groups, such for example as the existence of leaf-mining drosophilids.

In the extreme north of Madagascar, where recent volcanoes with rain forest co-exist with deciduous forest on limestone, sandstone or lateritic soils, a comparative study of the fauna has been most rewarding. Not only does it give many remarkable new forms but also helps in the understanding of factors underlying speciation, which is one of the most remarkable facts in the local fauna.

Some facts have been established on a firm basis and allow for biological discussion. For example, the remarkably active speciation referred to, with a high number of sympatric species, the numerous missing elements in the fauna as compared with continental Africa or the Indian subcontinent, the place and significance of the austral element, the wide plasticity of most new imported forms, etc. A number of principles underlying the building up of the fauna on small isolated islands have also been found. All these have shown that Madagascar was one of the most remarkable natural laboratories in the world for the study of species formation, adaptation and evolution. A considerable research effort should be started along such lines in the near future.

By necessity, the work until now has been mostly taxonomical, ecology has only been considered in so far as it opened up new biota, biological research has been limited to breeding work. But with the progress of the general catalogue of Madagascar's fauna research work on biology, ecology and physiology will soon be possible. If the method used has delayed a biological approach to Madagascar, it is believed that it has ensured a sure and efficient basis for such an approach and has saved many efforts and many errors due to an insufficient basic knowledge of the local fauna. It has in this way proved time-saving. The results of this Survey have shown also how completely misleading was the previous knowledge of a tropical fauna which one considered usually as fairly well known.

Thus it is quite evident that the Zoological Survey will never be finished, just as it is not finished in Britain or in France, but it may be brought to such a stage that, for most practical purposes, it can be considered as sufficient.

BIONOMICS OF THE BRUSH-TAILED OPOSSUM *TRICHOSURUS VULPECULA* IN NEW ZEALAND

By R. I. KEAN

Animal Research Section, New Zealand Forest Service, Wellington

DURING the latter part of the nineteenth century five Australian marsupial species were established in New Zealand—four wallabies, *Protemnodon rufogrisea*, *P. eugenii*, *P. bicolor* and *Petrogale penicillata*, together with one opossum, *Trichosurus vulpecula*.

Of the wallabies, only the first two cause loss to agricultural production, and that is not yet great because these animals occur only in restricted areas, but the opossum, which has some claim to being considered the most successful exotic mammal, is widespread, with an ecological range extending from suburban areas, through farm lands, to all types of forest. The significance of this animal to agriculture has not been thoroughly investigated, but in timber production serious loss has been caused through induced malformation of trees, mainly *Pinus* species, and in protection forests destruction of trees has been spectacular.

Economic need led to the commencement, in 1953, of systematic research on the opossum, and, to a lesser extent, on the wallabies.

Measures for control of the opossum will have to lean heavily upon a sound understanding of bionomics, but, since ecological steps are slow and are not well understood by the public, the more efficient use of poisons has been investigated, particularly methods involving application by aircraft.

Some opossum populations in New Zealand maintain balance with little artificial control, in these a female first rears an offspring in her third year, the kitten being ready for independent existence when the mother is 2 years 7 months old. A single kitten is reared in each succeeding year until about the tenth year. The bearing female exhibits little interest in the small young, but during the first two months of her kitten's pouch-free life she shows strong maternal attachment, and is aggressive towards other opossums

Under certain conditions (probably low population pressure, firmly established territory, and abundant food) some females rear their first young during their second year instead of in the third, and also rear two young annually

The female reproductive system is basically similar to its eutherian counterpart, both in that the vagina remains closed until first required for reproduction, and in that it is seasonally occluded thereafter The divergence from the eutherian lies mainly in the extreme heterochrony of development—the retention by the adult female of an embryonic tissue, the urogenital strand[2]—and in the relative lack of structure of the caudal portion of the vagina Both these marsupial characters appear to be simplifications permitted by the extreme specialization of the embryo, namely, its small size and its faculty for active locomotion before birth Seminal ducts, the so-called lateral canals, appear to have arisen phylogenetically, as suggested by T H Huxley[3], at some late prototherian stage of organization The opening of the median vaginal canal and the closing of the lateral canals during late pregnancy, apparently in response to hormones, support Huxley's hypothesis[4]

Œstrus is marked by desquamation of semicornified cells from the urogenital sinus The cycle, measured partly by smears and partly by direct observation, has been recorded by the writer as 22 or sometimes 23 days This is less than the 24½ day average (21–30) of Lyne[1] derived from smears that were made daily

Coition occurs on the night following œstrus (if œstrus is defined as the diel period of restlessness) and the single ovum is shed spontaneously approximately 24 hr later

The period of gestation was found to vary, apparently because of disturbance to the female Two pregnancies, timed from observed copulations, were completed in 17 and 18 days , others were lengthened, possibly to as long as 40 days when smears were taken, but this technique was usually associated with infertility One female from which smears were taken at two-day intervals was killed 28 days after external signs of pregnancy became obvious Copulation had occurred (ascertained by means of smear) 7 days before death The left ovary showed a 4 5-mm corpus luteum associated with a 4 8-mm blastocyst, and the right ovary an involuted 2 6-mm. corpus luteum associated with a 3 4-mm blastocyst In this case, superfœtation appeared to have occurred in the course of a prolonged gestation

Neither post-partum œstrus nor delayed implantation, as found by Sharman[5] in the wallaby *Setonix*, and almost certainly by Bowley[6] in the primitive phalanger *Cercartetus*, occurs in *Trichosurus* Sharman found that stimulation of the pouch by a contained young inhibited development of the post-partum blastocyst, but the present work on *Trichosurus* suggests that generalized stress applied to a female in early pregnancy resembles, in its effect upon the blastocyst, the maternal response to pouch young

Sperm have been found in the urogenital smear only from the third to fifth day post-coitus This result appears to be due to aspermous seminal fluid of the final ejaculation which, within about one minute, sets to form firm white copulatory plugs that completely fill the lumina of the lateral canals The plugs are later absorbed *in situ* Muscular occlusion and epithelial proliferation again seal the caudal ends of the lateral canals during early pregnancy

Male fertility, contrary to the findings of Bolliger[7] on captive opossums, shows endogenous fluctuations which may be cyclic The incidence of sperm is lowest during summer, when probably most males are aspermous for an overlapping two-month period, but, in addition to this, some males in all age classes are aspermous in each month of the year Regression of testis and urethral bulb occur, but these are not completely synchronous with the fluctuations of the cauda epididymis and its sperm

Reproduction is highly efficient Of the 106 adult females which were caught (excluding 15 pregnant or anœstrous ones) 90 carried pouch young and single corpora lutea on the ovaries, indicating almost certainly that for 84 9 per cent of this sample the first œstrus of the season had been fertile, and that the resultant young had been successfully established In the case described by Lyne[1] the newly born young's initial fall and its subsequent failure to take the teat might have been attributable to a defective maternal behaviour pattern induced by captivity

The growth of the young resembles that of man (on an equivalent time-scale) rather than that of a typical mammal , a long period of slow growth is broken by an intense adolescent spurt, which is followed by a further slow period which continues until maturity The opossum in its adolescent growth is less adaptable than man. who can defer the spurt when subject to stress , although the opossum takes three years to reach full maturity, rapid growth can occur only during the one restricted period[8]

The demands of the small young upon its parent are negligible during the first four months of life, and the bearing female passes through the period of winter stress in better condition than the male. The young makes its main growth in the spring, but slows down during the autumn period of maximum abundance, accumulating some fat before winter

Predation upon the forest opossum in New Zealand is applied only by man Natural regulation of numbers occurs through the low productivity The birth-rate can be greatly accelerated, when conditions are favourable, by the survival of young from the usually unproductive second-year juveniles, and by a spring breeding season supplementing the normal autumn one

An ultimate safeguard to forests, which are the natural habitat of the opossum, lies in the stenophagy that is characteristic of the Phalangeridae Only a limited number of tree species are killed (except by starving opossums)

Present forest destruction has two basic causes first, in the previous absence of herbivorous mammals, palatable tree species have grown in vulnerable compact stands which could not develop to-day , and secondly, euryphagous deer and goats, by the destruction of undergrowth, have both prevented forest regeneration and intensified opossum pressure upon the mature trees.

These investigations are continuing, and it is intended that full reports will be published later

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, December 7

Institution of Electrical Engineers, Electronics and Communications Section (at Savoy Place, London, W C 2), at 5 30 p m —Mr B B Jacobsen "Frequency Patterns for Multiple-Radio-Channel Routes"

University of London (at King's College, Strand, London, W C 2), at 5 30 p m —Prof Max Derruau (University of Clermont-Ferrand) First of three lectures on the "Central Massif of France" * (Further lectures on December 8 and 10)

University of London (at Queen Mary College, Mile End Road, London, E 1), at 5 30 p m —Dr M Eigen (Max-Planck-Institut fur Physikalische Chemie, Gottingen) "Relaxation Spectra of Fast Chemical Changes in Solution" *

Manchester Literary and Philosophical Society (in the Reynolds Hall, Manchester College of Science and Technology, Sackville Street, Manchester), at 5 45 p m —Dr J Needham, F R S "Hydraulic Engineering and Society in Ancient and Medieval China" (Wilde Memorial Lecture)

Society of Instrument Technology (at Manson House, 26 Portland Place, London, W 1), at 7 p m —Mr G Pask "Discontinuous Skill Teaching Machines"

Tuesday, December 8

Society of Chemical Industry, Agriculture Group (at 14 Belgrave Square, London, S W 1), at 10 30 a m —Dr T H Rose and Mr P H Brown "Experiments Comparing a Number of Conditions for the Improvement of Glasshouse Soils", Mr J Webber and Mr F W Shepherd "Experiments Comparing Bulky Organic Manures for Horticultural Crops", Dr F Haworth "Fertilizer Responses of some Vegetable Crops"

Institute of Marine Engineers (at the Memorial Building, 76 Mark Lane, London, E C 3), at 5 30 p m —Mr A Lindén "Recent Development of the Gotaverken Engine"

University of London (at Queen Mary College, Mile End Road, London, E 1), at 5 30 p m —Dr M Eigen (Max-Planck-Institut fur Physikalische Chemie, Gottingen) "Proton-conducting H-bond Systems and their Analogies to Electronic Semiconductors" *

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 5 30 p m —Dr L G Lajtha "Autoradiography in Bone Marrow Studies" (Fourteenth of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation * (Further lecture on December 10)

Royal Aeronautical Society (at 4 Hamilton Place, London, W 1), at 7 p m —Dr E K Armstrong and Mr R E Stevenson "Some Practical Aspects of Compressor Blade Vibration"

Wednesday, December 9

University of London (at the Postgraduate Medical School of London, Ducane Road, London, W 12), at 2 p m —Dr J D N Nabarro "Laboratory Investigations in Endocrinology" *

Institute of Physics (at 47 Belgrave Square, London, S W 1), at 6 p m —Sir Edward C Bullard, F R S "Geological Time"

Society for Psychical Research (at Leighton House, 12 Holland Park Road, London, W 14), at 6 30 p m —Dr Letitia Fairfield "Children and Witchcraft"

Oil and Colour Chemists' Association, London Section (at the Royal Society of Tropical Medicine and Hygiene, Manson House, 26 Portland Place, London, W 1), at 7 p m —Dr S H Bell "Electron Microscopy and Paint Technology"

Society for Analytical Chemistry, Biological Methods Group (at the Chemical Society, Burlington House, Piccadilly, London, W 1), at 7 p m —Annual General Meeting, followed by Dr H J Wallis, Mr S S Kind and Dr A S Curry "Biological Methods in Forensic Science"

Women's Engineering Society (at "Hope House", 45 Great Peter Street, London, S W 1), at 7 p m —Dr Elizabeth Laverick "Radar and Telecommunications Research and Development"

Wednesday, December 9—Friday, December 11

Crop Protection and Pest Control Exhibition (organized by *World Crops*, at the Seymour Hall, Seymour Place, London, W 1)

Thursday, December 10

Institution of Electrical Engineers, Utilization Section (at Savoy Place, London, W C 2), at 5 30 p m —Mr D B Corbyn and Mr N L Potter "The Characteristics and Protection of Semiconductor Rectifiers"

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 5 30 p m —Dr Sheila T Callender, 'Iron Absorption" * (Last of the fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation)

Thursday, December 10—Friday, December 11

British Institute of Radiology, incorporated with the Röntgen Society (at Church House, Westminster, London, S W 1)—Annual Congress and Exhibition

Royal Society (at Burlington House, Piccadilly, London, W 1), at 9 30 a m daily—Discussion on "The Biology of the Southern Cold Temperate Zone" opened by Prof C F A Pantin, F R S

Friday, December 11

Royal Aeronautical Society (at the Institution of Mechanical Engineers, Birdcage Walk, Westminster, London, S W 1) —Symposium on "Flight Safety" (All Day Discussion)

University of London (at the Postgraduate Medical School of London, Ducane Road, London, W 12), at 4 p m —Prof A Haddow, F R S "The Present and Future Relationship of Cancer Research to Medicine"

Institute of Physics (at 47 Belgrave Square, London, S W 1) at 6 p m —Mr J F Sayers "The Ultrasonic Camera—an Alternative Approach to Ultrasonic Testing"

Institution of Electrical Engineers, London Graduate and Student Section (at Savoy Place, London, W C 2), at 6 30 p m — Sir Willis Jackson, F R S "The Trends of Electrical Progress and Their Implications"

Royal Aeronautical Society, Agricultural Aviation Group (at 4 Hamilton Place, London, W 1), at 7 p m —Mr Peter King "Aerial Operations Planning in the United Kingdom—Results and Difficulties"

Royal Institution (at 21 Albemarle Street, London, W 1), at 9 p m —Prof R E D Bishop "The Menace of Vibration in Engineering"

Saturday, December 12

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S E 23), at 3 30 p m —Mr Philip Hunter-Jones "The Desert Locust" *

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Technical Officer (with a university degree or comparable qualification in physics or electrical engineering or other approved subjects) in the Department of Physics—Dr F B Kipping, University Chemical Laboratory, Lensfield Road, Cambridge (December 2)

Principal Scientific Officer (with research experience, preferably, but not essentially, in the chemistry of fats or related substances) in the Fats Research Laboratory of the Department of Scientific and Industrial Research, New Zealand, to undertake investigations on the composition and significance of fats and related substances, including phospholipids and sterols present in animal and plant tissues —The High Commissioner for New Zealand, New Zealand House, 415 Strand, London, W C 2, quoting Ref No B 11/21/22 and mentioning *Nature* (December 4)

Assistant or Associate Professor of Applied Mathematics—The Chairman, Department of Mathematics, McMaster University, Hamilton, Canada (December 10)

Lecturer or Assistant Lecturer (with at least a good honours degree in physics, and preferably experience in teaching and/or research) in Physics at the University of Malaya, Kuala Lumpur—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (December 15)

Lecturer/Senior Lecturer (with an honours degree in chemical engineering and some teaching or industrial experience) in Chemical Engineering at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (Australia, December 19)

Senior Lecturer or Lecturer in Pathology at the University of Khartoum—The Registrar, University of Khartoum, c/o Inter-University Council for Higher Education Overseas, 29 Woburn Square London, W C 1 (December 22)

Senior Technician or Technician in the Department of Bacteriology, and a Senior Technician or Technician in the Department of Surgery, University of Khartoum—The Registrar, University of Khartoum, c/o Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W C 1 (December 22)

Entomologist, Grade C (with a good honours degree in entomology (zoology) and a particular interest in biological control work)—The Director, Institute of Biological Control, Science Building, Carling Avenue, Ottawa, Ontario, Canada (December 31)

Head (with a degree in electrical engineering or Corporate Member of the Institution of Electrical Engineers) of the Department of Electrical Engineering—The Principal, Coventry Technical College, Butts, Coventry (December 31)

EXPANSION OF UNIVERSITY EDUCATION IN BRITAIN

IN an address to the eighth Congress of the Universities of the Commonwealth* at Montreal in September 1958, Sir Douglas Logan, principal of the University of London, opening a discussion on the establishment of new universities, expressed the opinion that in all parts of the world there is to-day a widespread demand for an expansion of the facilities for higher education which can be satisfied only by the creation of new universities. While he paid tribute to the way in which the scheme of 'special relation' had contributed to the growth in the post-war period of the new university colleges in the overseas Commonwealth, he pointed out that the scheme is costly both in time and man-power, making heavy demands on the university foster-mother. He believes, too, that in England we have reached the end of an era when apprenticeship under the London external degree system was the avenue by which an institution approached full university status, but nevertheless we are reaching the limit of expansion of our existing universities, and the problem of expanding facilities for higher education in the United Kingdom can, in his opinion, only be solved by the establishment of new university institutions.

Sir Douglas Logan believes that in this matter the initiative should come from outside, and that it is disappointing that the new University College of Sussex would only be the fifth to be founded in the United Kingdom since the end of the First World War. The founding of other university institutions is, of course, already being actively canvassed, for example, at York, at Norwich and at Bournemouth, and it will at once be realized that many aspects of long-term university policy are implicit in Sir Douglas's address. Apart from the question of where new university institutions should be established and how many, there are such questions as the size of a university, new or existing, what type or types of new institution should be established, the optimum size of its departments and faculties, their range of studies and, probably, the length of their courses. Nor can these questions be wisely considered without regard to Britain's existing resources, the desirable output of graduate and postgraduate students and the cover of faculties.

These questions have been the subject of increasing discussion in recent months. Early this year in *The New Scientist*, Prof. W. G. V. Balchin, of Swansea, argued that universities are a product of population and have risen in response to national, civic and regional needs. A new set of regional university colleges is desirable, he believes, to satisfy the future demand for places, to maintain the standards of existing institutions and permit experimentation. The belief is widely held that the optimum size of a university is between 3,000 and 4,000 students, but there is also strong support for smaller units of 2,000 to 2,500. Prof. Balchin listed a dozen or more regional centres for consideration where preliminary moves have been made.

The decision as to the number of new institutions must be determined by the desirable target for national output, as well as by the views held as to the appropriate size of individual institutions. The University Grants Committee has given a figure of 136,000 as a suitable objective for Britain before the end of 1960. The Association of University Teachers, however, estimates that the university population should rise to 176,000 by 1960, falling to about 145,000 a few years later. Present Government grants based on the first figure are expected to provide an annual output of 12,000 science and engineering graduates by 1970, and with 10,500 qualified men from the technical colleges, will increase the student-population ratio to something like 1 : 410.

To a large extent the argument for university expansion in Great Britain rests on the alleged need for more scientists and technologists, and the analysis of this need by Prof. John Jewkes in his presidential address to Section F (Economics) at the British Association meeting at York is accordingly highly important in assessing the desirable magnitude of university expansion as a whole. Inevitably, the striking of a right balance between the scale of scientific and technical activities and other activities is a matter of judgment, perhaps also of intuition. Prof. Jewkes suggests, in fact, that our knowledge about our scientific and technical effort is really very limited, and that we know little about even the true magnitude of the needs of Britain in man-power.

Prof. Jewkes does not believe that the universities of Britain are at present failing in their task of selection, and accordingly if more people are trained in them in the sciences and in technology, fewer of the ablest segment of the community will be trained in the other intellectual disciplines. This could be the more serious if there is, in fact, not simply in the undeveloped parts of the world, but also elsewhere, a growing need for more men of the administrative and managerial type, and for the pervasive spread of specialized skills of all kinds which Western countries take for granted. Indeed, important as it is that the administrator and manager should be aware of scientific and technical factors in a situation and able to assess their importance, it could equally be argued that the growing need of to-day is for the imaginative insight, the vision and capacity to assess human values that a humanistic education can inculcate—a view which President Eisenhower's

Science Advisory Committee appears to share in its statement, "Education for the Age of Science".

Here, indeed, the question of quality is all-important, and the possibility and consequences of still further increasing the proportion of failures (already higher in science and technology than in other subjects) in a policy of university expansion in which standards are not lowered must be considered. Here, too, it should be remembered that the decisive contribution to economic or industrial expansion and to scientific advance comes from the comparatively few outstanding and creative minds. The right question is undoubtedly, as Prof. Jewkes suggests, whether the community will gain by having more scientists and more technologists trained at the expense of non-scientists; but this too is linked with the question of quality and whether, in fact, we are at present employing our scientists and technologists to the best advantage and, in particular, providing them with the technicians and other assistance as well as equipment which are required to make the most efficient use of their services. Nor, as Prof. Jewkes also observes, can we overlook the competition which exists for the services of scientists, for example, between the need for teachers of science and scientists in industry or government service.

Prof. Jewkes is inclined to challenge the assumption that Great Britain is suffering from an unmet need for more scientists, and he is highly critical of the evidence or criteria on which the argument for such a shortage has been based. Neither international comparisons nor the attempts to correlate industrial output and the number of scientists and technologists are convincing; nor again does it appear reasonable to assume that, in proportion to size, every industry should spend the same proportion on research and development or devote the same proportion of its labour force to those ends. Measurement of the net gain arising from research and development is equally difficult, and there seems to be no strong evidence that the appearance of modern industrial research laboratories about 1930 has made any steeper the general upward trend in output per head. Again, comparing experiences of the different industrial countries since 1945 provides no very obvious correlation between the rate of industrial expansion and the resources devoted to scientific and technological effort.

Prof. Jewkes suggests, therefore, that we should continue to search for better criteria for determining how much the community should devote to science and technology, but points out that meanwhile the striking of a correct balance is not in itself a scientific process or one in which scientists should have the last word. He reminds us, moreover, that social discoveries in their totality may have contributed just as much to the rise of standards of living in the past two centuries as the technical inventions and scientific discoveries of the period. He does not suggest that we do not need more scientists and technologists; he does suggest that we should be clear as to the full implications of such expansion both in the universities and elsewhere, before we commit ourselves to a policy of expansion on any particular scale.

Lord Simon, in an article on university expansion in the *Universities Quarterly* of 1958–59 (13, No. 1), argued strongly for the establishment of a Royal Commission on the Universities to examine both university expansion and long-term university policy. He claimed that long-term university policy is scarcely considered by the University Grants Committee and that the Committee's very success in dealing with heavy and vitally important administrative matters leaves it little or no time to devote to matters of long-term policy. Lord Simon instanced many matters which such a body might consider, such as the question of halls of residence and the extent to which new universities should be primarily residential, and the relations between teaching staff and students, but without advancing convincing reasons why such matters should be considered by such a body as a Royal Commission rather than some appropriate committee appointed by the University Grants Committee itself.

There is, of course, involved here the fundamental question which Minister or Department of State should primarily be charged with university policy. Besides the Chancellor of the Exchequer, to whom the University Grants Committee is responsible, the Minister of Education and the Lord President of the Council are both involved; and Lord Hailsham has already made it clear that he regards university policy as to some extent falling within his new responsibility for fresh thinking about the whole structure of Britain's scientific and technical effort. This follows inevitably from his responsibilities for the Department of Scientific and Industrial Research. Such really prickly questions as the magnitude of the alleged distorting effects of the prestige and resources of the older universities in comparison with the new ones, and the implications and consequences of requiring a greater expansion in the scientific departments than academic circles regard as healthy for university life might well be handled by him without resort to the expedient of a Royal Commission, with its demands on men and women whose judgment, vision, authority and wide experience are already heavily engaged.

The question of a Royal Commission has again been raised by G. C. Moodie in a pamphlet issued by the Fabian Society. In "The Universities: a Royal Commission?"*, Mr. Moodie sets forth eighty-eight questions for consideration by such a commission without, however, seriously examining the justification for appointing a Royal Commission to consider all these matters, some of which are clearly comparatively trivial and others which Mr. Moodie himself admits could not usefully be examined by a purely United Kingdom Commission, since any action would necessarily have to be taken jointly by all the Commonwealth Governments involved. Here, it would seem that the Commonwealth Educational

Conference has already established the appropriate means. Indeed, of the seven questions dealing with Commonwealth relations detailed by Mr. Moodie, at least five or six came under consideration at the Oxford Conference last July.

It is only fair to point out that Mr. Moodie recognizes that not all the questions he lists need be answered by the proposed commission in detail, and that decisions on some might more appropriately be left to the University Grants Committee or the universities themselves. The terms of reference he proposes, however, are comprehensive: "to examine university education to-day, the role of the universities in modern Britain, and the ways in which the universities may best be enabled to fulfil that role in the foreseeable future; in making this examination to pay special reference to the number of students to be admitted to the universities, the internal government of the universities, the special positions within the nation of the Universities of Cambridge, London and Oxford, and the proper relationship with the public as represented by the institutions of Government, and with the rest of the educational system". He recognizes that the commission would require a special trained staff and that it would also need to make extensive use of sub-committees; but it is nowhere clear why, if the University Grants Committee were suitably strengthened on similar lines, it could not undertake the task at least as effectively. In any event, questions regarding the work of the University Grants Committee itself, its relations with the Treasury and the effectiveness of its control over the universities and of public accountability generally could only be satisfactorily handled by an independent body appointed by the minister concerned. Probably, as already suggested, this aspect could well fall within the review of the nation's scientific resources to which Lord Hailsham has already addressed himself.

From what Lord Hailsham has already stated, he intends to examine other questions which Mr. Moodie lists, such as the relations between the universities and the research institutes, the best means of encouraging university research, and the increase of private benefactions, particularly from industry, and for universities other than Oxford, Cambridge and London. Besides such problems of postgraduate study and research and the general financing of the universities, the specific questions listed by Mr. Moodie fall into three groups: specific problems of university expansion, including the limits imposed by the availability of qualified staff, problems of wastage, standards of admission, awards, residence and the like; the range and variety of university institutions; and university government and autonomy. The groups are not indeed sharply separated, but by and large the essential issues are clearly enough displayed; some large fields are expressly excluded, although they could be disregarded in any survey which sought to guide long-term university policy and particularly to influence the proportion of the national resources which should be allocated to the universities.

Whatever reservations may be entertained as to the means by which such questions as Mr. Moodie propounds should be examined, little exception can be taken to the propositions on which he affirms any university policy should be based. There will undoubtedly be an increasing number of school-leavers capable of profiting from, and demanding opportunities for, further education or instruction. The country needs more trained and highly trained citizens if it is not to decline into international insignificance and internal stagnation. Within any educational system, variety is essential and uniformity strongly antipathetical to choice and experiment, without which education must suffer in the long run. However these requirements are met, it will be costly, but it will be a productive and constructive form of national expenditure.

Of the first two propositions, it might be observed that further education does not necessarily mean university or higher technological education. The question of balance is as important as that of the amount of potential talent at present missed if full use is to be made of our resources of man-power—and incidentally, if the maximum satisfaction is to be given to the student not simply in his or her years of training but also in after-life. It might be added that due attention to this aspect is likely to afford the nation the most productive return from its expenditure on education at whatever level that is fixed.

Mr. Moodie is obviously opposed to the universities continuing to determine their own policies of expansion, and is dubious as to the alternative possibility of raising university standards and making wider use of other institutions for the less gifted. He seems to lean rather to a lowering of standards to something approaching the American level, though he admits that if this were done it would be essential to develop some institutions such as Cambridge, Oxford and possibly others to provide a particularly high level of education to highly selected students. He suggests that while this policy would mean that university education would become a comparatively common experience, this would be socially beneficial; and from this point of view would presumably repay the higher investment. Restriction of university entry by raising standards would also be beneficial, as it would ensure that the universities were not the only source of social leadership, and would allow them to stand more clearly for learning and research.

It seems likely that such fundamental issues as these will receive at least preliminary attention from Lord Hailsham, and if he considers that they need closer consideration by a Royal Commission, the recommendation would come with greater weight from his new position as Minister for Science. Probably in the first instance he will recommend, however, some further strengthening of the University Grants Committee so as to enable it to give more consideration to questions of long-term policy. The questions, however, of the effectiveness of the University Grants Committee itself, of the relations between the universities and the Government, the magnitude of the resources which should be placed at their disposal and the channels by which they should be made available are certain to be examined independently by Lord Hailsham. His comments and recommendations here will be awaited with as much eagerness and interest as his proposals regarding relations between the Minister of Education, the Chancellor of the Exchequer, the Lord Privy Seal and other departmental ministers, who are in some degree responsible by the training of scientists and technologists and the use of their services.

CURRENT RESEARCH ON REPRODUCTION AND FERTILITY

Studies on Fertility

The Endocrinology of Reproduction

Edited by Prof. Joseph Thomas Velardo. Pp. viii+340. (New York and London: Oxford University Press, 1958.) 120*s.* net.

A NOTABLE feature of the new volume of "Studies on Fertility" is the publication of a group of papers on the use of synthetic progestins which, when administered orally, suppress ovulation and thus prevent conception in women. Dr. Gregory Pincus, one of the investigators originally concerned in the development of norethisterone (norlutin), norethynodrel (enovid), and similar compounds as potential oral contraceptives, reports favourably on the outcome of trials in Puerto-Rican women, and shows that a recovery of normal ovulatory function and fertility takes place readily after the cessation of medication. He, and Dr. Jackson, both mention, however, the disturbing side-effects of the oral medication, such as nausea, vomiting, dizziness, headache and abdominal pain which, though infrequent, yet require further investigation before synthetic progestins are adopted on a large scale as a safe and reliable means for the control of human fertility. Other papers in the same volume reflect adequately the various lines of advance in research on the physiology and pathology of human and animal reproduction. They cover a multitude of problems ranging from psychiatric and surgical aspects of human infertility to successful attempts of inducing conception in the guinea pig by injecting spermatozoa into the peritoneal cavity. Contributions to the physiology of gametes include new observations on the transfer of mouse eggs and on the effects of varicocœle, cryptorchidism, and ischæmia on testicular function in mammals, as well as new findings relating to the occurrence of some remarkable species differences in sperm metabolism of the boar, ram, stallion, bull and man.

The volume is a good example of progress achieved by an interchange of ideas and observations between clinical investigators, concerned primarily with the problems of human fertility, and the laboratory workers whose efforts are concentrated in the main on the more basic problems underlying the reproductive processes in animals. Now that the recently announced *Journal of Reproduction and Fertility* is going to replace the "Studies in Fertility" as the official organ of the Society for the Study of Fertility, one hopes that its editors will be able to extend even further the range of papers, while maintaining in the new publication the standard which distinguished the parent journal.

Like "Studies in Fertility", the Proceedings of the Symposium on Reproduction and Infertility, held under the auspices of the Colorado State University, illustrates well the tendency among research workers in the field of reproductive physiology to pay increasing attention to comparative aspects, in an endeavour to link up studies on human and animal fertility. Of the twenty papers given at that symposium, more than half deal with problems in cattle, mainly with the incidence and causes of vibriosis, vaginitis, malignant tumours of genital organs, and sterility of the so-called repeat-breeder cow. Those interested in human reproductive disorders will find especially interesting and instructive the chapter by Nowakowski, on the classification of male hypogonadism, based to some extent on the chemical analysis of semen, and Reifenstein's survey of new long-acting progestins and their use in maintaining human pregnancy and preventing abortion.

Progress in research concerned specifically with human reproduction naturally forms the main theme of "Essentials of Human Reproduction", a text-book written by thirteen specialists representing various medical schools in the United States, and edited by Prof. Velardo, of the Yale University Medical School. An attractive feature of this book and its companion volume, "The Endocrinology of Reproduction", is the emphasis which the authors have placed on existing problems in the physiology of reproduction and on current research problems. Both books are, moreover, notable for the inclusion of numerous illustrations, some of them reproduced from the monumental "Ciba Medical Illustrations" of Netter, others originating from Robert Wabnitz. "Essentials of Human Reproduction" contains discussion of all the main stages of the normal reproductive process in man, and tackles in addition the various disturbances of human pregnancy, endocrine disorders of the testis and ovary, and different forms of infertility. "Endocrinology of Reproduction", written alike for research students and specialists, includes, in addition to chapters on male and female endocrinology, some information on closely related subjects such as the genetics of reproduction and the anatomy and embryology of the male and female reproductive systems. As with most text-books written by several authors, there is a certain amount of overlapping. Research students will also find that some chapters of the text-book are much easier to follow than others, and they may have some difficulty in deciding which of the copious references should be selected for further reading. This, however, does not detract from the value of the book to the specialist, both as a concise and up-to-date survey of the subject and as a useful compilation of relevant literature T MANN

FORMALIZATION OF CONSTRUCTIVE CONCEPTS

Constructivity in Mathematics

Proceedings of the Colloquium held at Amsterdam, 1957 Edited by Prof A Heyting (Studies in Logic and the Foundations of Mathematics) Pp viii+297 (Amsterdam · North-Holland Publishing Company, 1959) 60*s*

THIS volume consists of 25 articles by 23 authors The central themes are intuitionism and inductive definitions The two fundamental steps in the background are Heyting's formal systems to embody Brouwer's ideas on logic and mathematics, and a classical formalization of the concept of effectively calculable functions by general recursive functions As a result of these steps, a more formal treatment, congenial to the logician, of intuitionism and constructive mathematics in general becomes possible Much of the book is devoted precisely to questions arising from such a treatment Since in classical mathematics we are concerned with not only natural numbers but also real numbers and real functions, a major problem is to extend the notion of recursive functions to those of objects of higher type, that is, to define computable or constructive functionals Kleene's paper on countable functionals, the papers by Davis, and by Kreisel–Lacombe–Shoenfield deal with this problem In addition, Kreisel and Kleene each gives an interpretation of intuitionistic analysis by applying constructive functionals

Another problem is to 'reconstruct' classical mathematics by restricting arbitrary functions to constructive ones This leads to the study of constructive, in particular, recursive, analysis and topology The articles by Goodstein, Grzegorczyk, Lacombe and Specker are taken up by this The three papers by Rasiowa and Sikorski are concerned with formal considerations on Heyting's calculus of intuitionistic logic

Fitch gives a consistent formal system which contains the theory of combinators and "extended basic logic" Myhill proves theorems on "finitely representable functions" which appear to be essentially the same as the Herbrand recursive functions reported in Godel's lectures of 1934 Hermes and Wette study certain problems about the "operative" logic and mathematics

The remaining nine articles are of a more general or a more philosophical character Heyting makes some familiar but pertinent remarks on intuitionism , Beth comments on his own formal treatment of the intuitionistic logic Kalmár argues against the hypothesis that every effectively calculable function is general recursive , Péter disputes that every general recursive function is indeed effectively calculable Lob tries to formalize concepts such as event, brain, subject, mental occurrence of a subject, perception, in terms of constructive ideas Nelson considers the meaning of falsity in empirical characterizations of truth, as well as the situation that classical logic identifies certain constructively distinct entities Lorenzen stresses the importance of inductive definitions for constructive mathematics Mostowski discourses on various degrees of constructivism Bernays gives a free-variable, complete formal system as a natural extension of the calculus of relations

If we summarize the concepts and methods of foundational studies under the five headings of anthropologism (strict finitism), finitism, intuitionism, predicativism (inductivism), and platonism, the book is mainly concerned with intuitionism and a part of predicativism This is perhaps not surprising since platonism falls outside the domain of constructivity, while the principles of anthropologism and finitism are not yet sufficiently clarified to admit a direct mathematical handling HAO WANG

BIRDS OF PREY

Pirates and Predators

The Piratical and Predatory Habits of Birds By Colonel R Meinertzhagen Pp ix+230+44 plates (Edinburgh and London Oliver and Boyd, Ltd , 1959) 70*s* net

THE author of this handsome volume emphasizes that it is a contribution and not a monograph The value indeed lies in the record of original observations made in the course of long experience in Europe, Africa and Asia Economical of words, the writer has a happy knack of conveying a vivid impression of what he has seen His touch is less sure when he cites the records of other observers, but in any event he disclaims an exhaustive representation of the literature

An opening chapter deals with various general points, such as the food preferences of individual members of a predatory species, the regular beats and hunting territories of some, relative size of the usual victims, methods of killing and of preparation for eating, and the reactions of other birds to predators Throughout, particular attention is paid to the occurrence of 'piracy', that is to say one species robbing another of its prey, occasionally in some instances and regularly in others The habits of mammals and reptiles receive frequent mention

Group by group, Colonel Meinertzhagen then briefly reviews predatory and piratical habits among the birds which he rather whimsically classes as 'amateurs', those outside the Falconiformes and Strigiformes Species by species he next deals with many of the 'professionals', the true diurnal and nocturnal birds of prey in which he is especially interested This is the longest section of the book and covers examples of hunting for many types of prey—insects, molluscs, fish, reptiles, birds and mammals—some species being highly specialized in this respect and others more versatile Flying prey may be secured by level pursuit or by 'stooping' from above prey on the ground may be located from flight (quartering, soaring, hovering), from a perch or from the ground itself (secretary-bird) , then there are the fishing hawks, the eaters of carrion and the partly vegetarian palm-nut vulture One would have welcomed some sort of general review of these topics, in addition to the piecemeal presentation

Finally, there is a chapter on what the author terms 'autolycism', that is to say, making use of other animals (including man) but not as victims There are the many birds which nowadays usually nest on buildings or which have developed feeding habits geared to human activities There are various associations of birds with mammals, both wild and domesticated, exemplified by the habits of the cattle egret and the ox-peckers There are associations between different species of birds, and breeding parasitism is just mentioned As regards associations with reptiles, Colonel Meinertzhagen has personally witnessed both *Pluvianus* and *Hoplopterus* picking the teeth of crocodiles

The colour plates are mostly from pictures by the late George Lodge, but one of a lammergeier from a tapestry by the author is of note ; the drawings and photographs are from various sources

Landsborough Thomson

KEEPING UP TO DATE WITH CHROMATOGRAPHY

Chromatographic Reviews

Progress in Chromatography, Electrophoresis and Related Methods, Vol 1 Edited by Michael Lederer Pp ix+276 (Amsterdam Elsevier Publishing Company , London D Van Nostrand Company, Ltd , 1959) 45*s*

PREVIOUS editions of two of these books are already well known The new editions of Block, Durrum and Zweig's "Manual" and of Cramer's "Papierchromatographie" maintain the high standard of their predecessors Both incorporate recent information and improvements in arrangement of subject-matter Because they are about subjects that are still growing rapidly, it is not surprising that these books are somewhat larger than previous editions Block, Durrum and Zweig's book is half as big again as their first edition of 1955, and has become rather bulky for a practical manual Cramer's book has also put on weight but it is still slim enough to carry around the laboratory without undue strain Cramer's exposition of paper chromatography remains less highly detailed and he deals only in outline with paper electrophoresis, whereas Block, Durrum and Zweig are faced with the problem of coping adequately with both techniques within the covers of one book Block and Zweig's section is a detailed and up-to-date account of the paper chromatography of very many substances, amply illustrated with photographs, diagrams and tables of R_F values The bibliography covers the literature up to the end of 1956 and occupies no less than 45 pages New features in Durrum's section on paper electrophoresis include recent developments in recording and integrating densitometers, radioactive scanners and improvements in curtain electrophoresis and other methods All the theory is now covered in one chapter instead of being split up as previously There is also a very full bibliography (about 2,000 references as compared with 300 in 1955) and a useful classification of electrophoretic applications Cramer's book covers much of the subject quite adequately for most purposes It is also well illustrated and has many tables of R_F values The colour reproductions are extraordinarily good The book is attractively printed and will appeal primarily to German-speaking workers

In 1954, under the editorship of Hais and Macek, the comprehensive Czech treatise "Papirova Chromatografie" was published Afterwards, the editors decided to prepare a new edition of this work in two volumes, the first to cover fundamentals and techniques, the second to cover applications and bibliography Also a German translation of this new edition was planned, and Vol 1 in German was published in August last year However, the original Czech edition, which I have not seen, was published only a few months ago Comparing the first Czech with this German edition, the conversion has been accompanied by a great improvement in appearance and the quality of printing and paper is now high There is no doubt that this massive work (mistakenly entitled "Handbuch') is the most complete exposition of paper chromatography that exists Theoretical aspects are dealt with fully and the many methods and applications are covered with remarkable thoroughness A number of features deserve mention There are supplements to every chapter and all are collected together as an appendix which gives full directions for preparing location reagents, for pretreating substances before chromatography and for pretreating paper when special modifications of chromatography are required Many of the R_F values are conveniently recorded in diagrammatic form There are excellent surveys of methods for structural analysis of large molecules, particularly proteins The book is published in Eastern Germany and copies may not be easily obtained in Western countries, though I have been informed that there is no such difficulty in Western Germany

It is striking how frequently new editions of books on chromatography are appearing Cramer's is the fourth since 1951, Block, Durrum and Zweig's is the third since 1952 if the "Manual" published that year by Block, Lestrange and Zweig is regarded as the first edition Hais and Macek's is the second in four years It would appear that authors of such books are obliged to think about preparing new editions as soon as they are published Nevertheless, for many and perhaps most purposes the earlier editions are still quite adequate and indeed they are largely incorporated unchanged in the new editions (It must also be admitted that some of the subject-matter has become dead wood, but there seems to be a reluctance to cut it out) The admirable efforts of the authors to keep their books on the whole field of paper chromatography abreast of the times may eventually prove to be an impossible task, because the subject continues to grow at an ever-increasing rate The alternative is to select a limited number of topics and give as much information as possible about each This is the purpose of Lederer's "Progress in Chromatography" and Vol 1 is the first of a series to be published at intervals (how frequently is not stated but presumably yearly) The series will be concerned with all forms of chromatography and with related methods, including electrophoresis For this volume some of the articles have been specially written while others are taken from the *Journal of Chromatography* and all are in English There are nine articles each contributed by specialists Two are concerned primarily with techniques, namely, "Chromatostrips and Chromatoplates" (Demole) and "High Voltage Electrophoresis" (Michl) Both are most useful contributions because the first describes an elegant technique which deserves wider recognition and the second deals with a method which is attracting more and more interest The other articles are on chromatographic and electrophoretic methods applied to the following special groups mould metabolites (Reio), strychnos and curare alkaloids (Marini-Bettolo and Casinovi), sterols and steroids (Neher)—probably the most thorough survey of this group that has been written—chloroplast pigments (Šestak), anthocyanins (Harborne), inorganic phosphorus compounds (Hettler) and isotope separation (Chemla) For anyone interested in these topics, the articles offer very detailed well-presented and up-to-date information If future volumes maintain as high a standard as Vol 1, the series will undoubtedly form a most valuable contribution to the literature of chromatographic and related methods

R Consden

NEW TECHNIQUES IN PACKAGING

Pressurized Packaging (Aerosols)

By A. Herzka and J Pickthall Pp xi+411 (London. Butterworths Scientific Publications, New York Academic Press, Inc, 1958) 63*s*

THE pressurized pack is a method of packaging and dispensing small quantities of a large variety of materials and has developed rapidly in recent years For products like hair lacquers it is probably ideal, for many others it is efficient and convenient, but expensive, and the relatively high cost may or may not offset its many advantages The pressure pack of horticultural insecticide is excellent for treating a treasured plant, but for pest control on a large scale gardeners who are not millionaires are soon forced back to the old bucket of derris

Herzka and Pickthall's book is an encyclopædia of the subject and is in fact source book, laboratory handbook, trade directory and recipe book all in one A short general section explains the general methods of operation of two-phase and three-phase systems Section B deals with propellants, containers, valves, methods of filling and the laboratory checking of finished packs from the points of view of safety, (in)flammability, spray size and pattern, moisture content, etc A considerable mass of information is collected together in its numerous tables and graphs Section C gives detailed instructions for the pressurized packaging of products ranging from foodstuffs to paint strippers, cosmetics to anæsthetics The special precautions necessary in packaging these different commodities are described and ample recipes are given The volume concludes with a glossary of abbreviations and technical terms, trade names of materials and suppliers, patents, particulars of industrial methylated spirits and a world list of suppliers of containers, valves, propellants, sealing equipment, laboratory apparatus, etc There are both author and subject indexes

This is a valuable reference work, well produced and printed Errors are few The illustrations are the weakest part Some of the line drawings are confusing, with the essential parts on too small a scale for it to be clear how the mechanism operates (for example, Figures 64 and 65) Not a few of the half-tone illustrations are of poor quality and not very informative These are, however, minor blemishes in a work that, containing much information in small compass, deserves wide circulation

V G W Harrison

TECHNOLOGISTS AND TECHNICIANS

Sandwich Courses for Teaching Technologists and Technicians

By Dr P F R Venables With a contribution by R Ratcliffe Pp 160 (London Max Parrish and Co, Ltd, 1959) 18*s* net.

DR P F R VENABLES is one of the most able practitioners and protagonists of technical education in Great Britain and his speeches and writings are treated with deserved respect In this, his latest publication, he has collected information about the so-called 'sandwich' courses for producing technologists and technicians which have grown up in such mercurial fashion over the past few years This information is set down with characteristic vigour and supported by views which are never lacking in candour or clarity Whether the book will have much vogue, however, is open to question Much of it contains information about routine administrative procedure necessary for running successful sandwich courses and will be already quite familiar to those concerned with running such courses

Where the book is likely to make an impact is among those principals of smaller technical colleges who are determined not to be left off the 'sandwich band-wagon' and who appear to put the prestige of their colleges before the genuine interests of their students Dr Venables makes it very clear that many higher national diploma and college associate courses would never have come into being if regional advisory committees had carried out their commitments with courage to repel over-ambitious local projects He also makes it clear that the time has come when colleges of advanced technology should take their rightful place alongside universities, heads of departments should become professors (has he not heard of the Royal Technical College, Glasgow, and Manchester College of Technology ?), eminent industrialists and technologists should be appointed to the part-time staffs as consultant professors, and research fellowships should be readily available to those more interested in teaching than research

Few would deny the strength of Dr Venables's arguments and most concerned with the progress of technical education in Great Britain would support him Perhaps his views about sandwich courses and related matters would have carried greater weight, however, if he had left the preparation of this book until sandwich courses had emerged from their swaddling clothes

Automation and Society

Edited by Howard Boone Jacobson and Joseph S Roucek. Pp. xiv+553. (New York Philosophical Library, 1959.) 10 dollars

A RESOLUTION accepted by the House of Commons on May 1 in a debate on automation requested the Government to undertake an intensive study of the probable consequences of its introduction and to invite industry to co-operate in effecting the necessary changes with a minimum of hardship to its employees. In the debate, which was concerned largely with the bearing of automation on employment, reference was freely made to the report on the technical trends of automation and their impact on management and labour issued by the Department of Scientific and Industrial Research some three years ago and to subsequent inquiries in this field which have been supported by the Department The present book does not provide the type of report which was visualized in the debate as contributing most decisively to co-operation but the sections dealing with automation and responsibility and with automation and society could assist that task of education or increasing the public understanding upon which alone such co-operation can be firmly based Apart from the first, in which Mr P T Veillette outlines very clearly the development of the concept of automation, the sections of this book are the composite work of some thirty authors, that on automation applied dealing specifically with its application in some fourteen fields in the United States The other two sections are of greater interest to British readers, but on the whole they scarcely bring out the social implications any more clearly than was done in 1950 by the Department of Scientific and Industrial Research's report The section on automation and society includes a useful dictionary of automation, but the 37 short case-histories of automation in the United States of America and Canada compare poorly with the three case-studies in automation published by Political and Economic Planning in 1957 It is difficult to believe that the book could not have been considerably compressed with great advantage, and the inclusion of brief biographies of contributors does not compensate for the omission of an index or for the scattering of selected bibliographies, some annotated, at the ends of chapters

R BRIGHTMAN

Metal Fatigue

Edited by Dr J A Pope Pp. xiv+381 (London Chapman and Hall, Ltd , 1959) 70*s* net

READERS of Nevile Shute will probably be surprised to realize that the unreceptive attitude of engineering designers to Mr Honey's ideas on fatigue was until fairly recently an authentic picture of the state of affairs in the engineering industry Several unfortunate aircraft crashes, which were proved to be initiated by fatigue failure, have, however, been in part responsible for a change of heart, and the more forward-looking engineers are now very much exercised by the problem of making allowance for the effects of vibrational stress on their structures Their task of producing a safe but economical design is not easy ; the amount of reliable data which are available is at present inadequate and, since several uncontrolled variables affect the fatigue life, a statistical approach is essential The volume under review should be a real help , it reproduces twenty lectures given in the Engineering Department at the University of Nottingham during a Summer School on the Fatigue of Metals The professed aim of the editor is "to present to practising engineers the known facts about metal fatigue and its effects on design" This is therefore a book primarily for engineers, although much of it will be read with profit and fascination by metallurgists and others interested in the wayward behaviour of stressed solids

The work is divided into three main sections the basic phenomena and, so far as it exists, their explanation , fatigue properties of engineering materials and components , and fatigue testing of engineering components The fifteen contributors have produced a readable, clearly presented and useful picture of the state of knowledge in 1955 The engineering designer will draw some comfort from a perusal of the book, particularly from the realization that the problems of fatigue, as they affect him, are being subjected to competent and energetic scrutiny He will see that already in some directions solid progress has been made, notably in our knowledge of the true stress intensification at cracks and notches, but he may wonder what further developments have taken place in the four years between the compilation of the material for the lectures and the appearance of this book.

K M ENTWISTLE

Principles of Modern Physics

By Prof Robert B Leighton. (International Series in Pure and Applied Physics) Pp xii+795 (London: McGraw-Hill Publishing Company, Ltd , 1959) 97*s*

THIS addition to the present series is most welcome The author has tried to write a book suitable for students of physics in their final year and for specialists in other subjects who require a broad general background It caters very well for the former group By assuming a considerable background of mathematics and classical physics a great deal of tedious digression, common in other books, is avoided The special theory of relativity, once relegated to an appendix, has, at last, achieved its rightful place—the first chapter , atomic and molecular spectroscopy, so often the major topics, are confined to about seventy pages More than one-third of the book is devoted to nuclear physics The book is very comprehensive and up to date It includes such topics as parity, band theory of solids and X-ray diffraction Work published as recently as 1958 is referred to Occasionally, the material becomes too condensed for easy reading, but frequently the exercises are very well designed to supplement the text. Other exercises vary from simple logical extensions of the preceding sections to difficult problems which only a very good student could be expected to solve without assistance Rationalized M K S A units are used throughout the book, although some of the formulæ are also given in what must still be regarded as their more familiar form, and there is a useful appendix of atomic constants in M K S A units

E STANLEY

Directory of Nuclear Reactors

Vol 1 . Power Reactors Pp ix+214 (Vienna International Atomic Energy Agency, 1959) 73 50 schillings , 21*s* , 3 50 dollars

THIS directory makes available the important details of power-reactor projects, throughout the world, which will be producing electric power by the end of 1962 , reactors with an electric power output of less than 2 MW are not included Information is presented for each reactor under the following headings general, reactor physics, core, fuel element, heat transfer, control, reactor vessel, fluid flow, shielding, containment, turbo-generator, cost and staff In almost every case diagrams are also provided of the fuel element, two sections of the reactor, and the fluid-flow sheet for the system The information is as up to date as can be hoped for , in every case, except one, it is dated between December 1958 and April 1959 Useful conversion charts and space for notes are also provided The directory is comparable with a similar compilation published a month earlier by the American Society of Mechanical Engineers It is better than the American publication in that the information on any particular reactor is fuller and more reactors are covered, for example, the Russian reactors are included

The book is very good value for its price, but a more substantial backing would be an improvement as the present one is very liable to damage A minor point is that a conversion scale from mills to pence would also be a help The few mistakes noted were all trivial In general, such a directory is required, the International Atomic Energy Agency appears to be the best organization to carry out such work, and the first volume is a good start A J SALMON

The Birds

By Oskar and Katharina Heinroth English edition prepared by Michael Cullen Pp 175 (London Faber and Faber, Ltd , 1959) 18*s* net

ORNITHOLOGY provides many fascinating problems, such as how birds mate, migrate, eat, sleep, and so on, which are a source of interest to an increasing number of people Lack of easily available and authoritative information has given rise to a number of popular misconceptions Mr Cullen states that Oskar Heinroth knew this because of his contact with people at the Berlin Zoo, where he was curator for many years That is the reason given for the book which Heinroth published in 1938 and which was revised by his wife in 1954 after his death in 1945 It is said that in this English edition certain parts of the text have been brought up to date

Though mainly and intentionally limited to certain aspects of bird biology in which Heinroth was particularly interested, for example, the development of nestlings, a wide range of information is provided which will satisfy the curiosity of many who want to know more about birds than merely their names There is ample scope for works of this kind, which are singularly lacking among the numerous bird-books Although appreciating the value of this one and the skill of the translator, one regrets that a need should have to be satisfied in this way, for translations, inevitably, lack the freshness of original thoughts It is a pity that the wealth of present-day photography was not used to give the illustrations a modern look

Mineralogical Study on Clays of Japan

By Dr Toshio Sudo Pp vii+328 (Tokyo Maruzen Co , Ltd , 1959) 2,000 yen ; 10 dollars

THOSE who have followed the recent literature on the clay minerals of Japan will be aware of the outstanding contribution made by Dr Sudo and his collaborators They will probably welcome, as does the reviewer, this collected account of his researches Although much of this material has already been published in various Japanese and foreign journals, its re-publication in volume form is justified on grounds of convenience in reference

The author has been quite uninhibited in his approach, and this book, being a report on research in progress, will inevitably be found wide open to criticism on many points Numerous details will have to be revised later, by the author himself or other workers But in its imaginative application of up-to-date techniques, the book is almost a model In most chapters, the reviewer found things to set him thinking along new lines, as well as things to disagree with

Most of the book is devoted to specific minerals and clay deposits The first seven chapters are general in nature, and the reviewer feels less happy about them Arguments, at times hard to follow, often seem to tail off inconclusively

The presentation is excellent, but the book needs an alphabetical index, even though there is a very full table of contents The language is, alas, only adequate at best, and at worst verges on unintelligibility The number of printing errors is more than would be tolerable in an English or American book We cannot expect authors to be expert linguists Surely the blame rests with the publishing house, which is one of international repute If they publish in English, they should ensure that adequate linguistic assistance is available D M C MACEWAN

Progress in Organic Chemistry

Vol 4 Edited by Dr J W Cook (Progress Series) Pp ix+256 (London Butterworths Scientific Publications , New York Academic Press, Inc , 1958) 50*s* , 8 80 dollars

THE choice of subjects for this volume is significant in that it reflects the present dominating position of natural products in organic chemistry Also symptomatic of current thinking is the inclusion of biogenetic considerations in both a predictive and interpretative role Of the four chapters devoted to natural products the most extensive is a very fully documented account by A H Cook and G Harris on the degradation and synthesis of peptides and proteins F D Gunstone reviews naturally occurring unsaturated fatty acids Notable here are the stereospecificity of recent synthetic procedures and the large emerging group of acids from compositous plants and micro-organisms, presenting a spectrum of ethylenic, acetylenic and allenic unsaturation

2-Acylcyclohexane-1 3-diones from sources as diverse as the male fern, hop resins and certain essential oils are discussed by C H Hassall in a chapter which also includes the widespread lichen constituent usnic acid, the recent synthesis of which underlies the probable role of oxidative phenolic coupling in biosynthesis That this concept may have wider significance is apparent from recent work on the spirocoumaranones griseofulvin, geodin and erdin which, together with methylene quinones, chromenopyrones and depsidones, are included in a chapter by W B Whalley on oxygen heterocyclic fungal metabolites F G Mann surveys recent syntheses of phosphorus, arsenic and antimony heterocycles, mostly from his own laboratory B and A Pullman contribute a theoretical discussion of free valency and correlate it with a selection of physical and chemical properties in aromatic hydrocarbons Once again the chapters of this book reflect the erudition and enthusiasm of experts discoursing within their chosen fields of interest K H OVERTON

RECENT WORK ON THE ELECTRON MICROSCOPY OF VIRUSES*

By DR. KENNETH M SMITH, C B E, F.R S
Agricultural Research Council Virus Research Unit, Cambridge

THE conception of a virus as a mysterious, almost supernatural, entity dating from Mayer's studies on tobacco mosaic virus in 1886 persisted up to quite recent times, and learned discussions were held as to whether viruses were particulate or not No one, however, suggested what they were if they were not particulate, and Beijerinck's famous conception of a "contagium vivium fluidum" was still quoted As lately as 1932, T M Rivers stated with a good deal of justification that the size of no virus was accurately known

The first indication of the shape of a virus was given by two American workers, Takahashi and Rawlins, in 1933, who observed that the sap of a tobacco plant infected with the mosaic disease showed the phenomenon of double refraction when made to flow and viewed by polarized light This indicates that the sap contained rod-like entities, an observation amply confirmed in later years

Apart from the so-called elementary bodies of certain animal virus diseases which came within the resolution of the optical microscope, the first actual pictures of a virus particle were made by Barnard with his ultra-violet light microscope It was only possible, however, to resolve some of the larger animal pox viruses, and no details of the particles could be seen It was not until the invention of the electron microscope that any conception of what a virus really looked like was obtained

The improvements in the electron microscope and the developments in the techniques for the study of viruses during the past ten years have been very great, and it is only possible to indicate them here without any technical description

The first virus to be observed on the electron microscope was that of tobacco mosaic, and the particles were shown to be rod-shaped, as had been predicted earlier by other methods The first electron micrographs of this virus showed only that it was a rod-shaped particle and no other details were visible It is by comparing these early pictures with modern electron micrographs of the same virus that some idea is obtained of the great advances which have been made in electron microscopy

Metal Shadowing

Williams and Wyckoff[1] developed a method of shadow-casting in which metal, evaporated from an electrically heated filament in a vacuum, impinges on a specimen from a sufficient distance so that the metal atoms arrive in almost parallel straight lines The metal, being more opaque to the electron beam, casts a shadow, thereby giving a three-dimensional effect to the objects ; this gives micrographs which are a great improvement on the flat and rather characterless pictures previously obtained Metals for shadow casting should not show a granularity which might obscure the structural detail of the object ; several have been used, and they include chromium, gold and platinum alloys, and uranium

Thin Sections

The development of the ultra-microtome for cutting ultra-thin sections has marked a great advance in electron microscopy In the early days sections were cut at a high speed and of a wedge shape, the thin end only being examined Nowadays, however, the technique has become almost ordinary laboratory procedure There are various types of ultra-microtomes on the market ; one or two still make use of steel knives, but the glass knife, made by fracturing a strip of plate glass, is more widely used Recently, the diamond knife, made from a polished industrial diamond, has become popular The advantages of this are its extreme hardness, its durability—it can be used continuously instead of only once as with the glass knife—and its suitability for cutting hard objects Very fine results have been achieved with the diamond knife but it requires great care in its manipulation (Figs 1 and 2)

A good operator with either glass or diamond knives should be able to cut sections of 300–400 A in thickness

The embedding medium is important, the most popular being a plastic made by the polymerization of butyl and methyl methacrylate[2] Other media are 'Vestopal' polyester resin[3] and 'Araldite' epoxyresin[4] ; all these require dehydration with ethanol Just recently, however, another embedding medium, to which the name 'Aquon' is given, has been described ; this medium is miscible in water and avoids the necessity of using dehydrating agents[5]

New Staining Methods

The standard method of fixing virus materials for electron microscopy is to use buffered 1 per cent osmium tetroxide, and this acts as a stain as well as a fixative Recently, however, a number of new staining techniques have been developed ; one of the most successful of these is phosphotungstic acid, and Selby[6] has used this acid at a concentration of 1 per cent adjusted to pH 5 4 Other useful stains are 1 per cent phosphomolybdic acid buffered at pH 5 4 with phthalate buffer[7], chrome gallocyanin[8], 0 1 M ferric chloride[9], mercuric bromophenol blue[10] and 0 5 per cent uranium acetate buffered at pH 6 1 with veronal acetate buffer[11] The last-named has proved very successful with insect virus sections

Supporting Films

For several years the standard supporting film on the grid was one of collodion or 'Formvar', and these are still used for routine work The increasing resolution of the electron microscope and the decreasing thickness of the sections, however, led to

---

* Substance of a University of London Special Lecture delivered on October 29

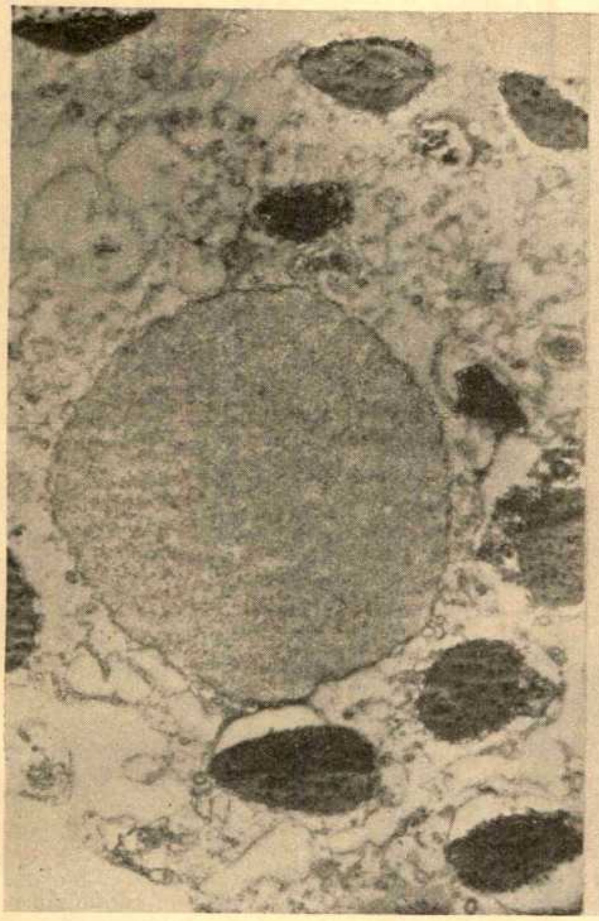

Fig. 1

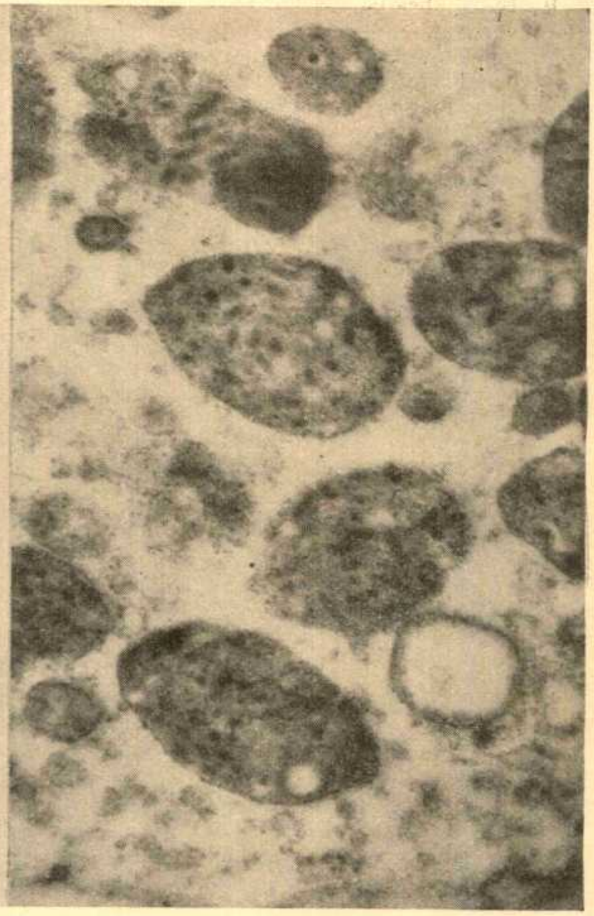

Fig. 2

Fig. 1. Ultra-thin section of a blood cell from the larva of *Tipula paludosa*, the crane fly, infected with a nuclear polyhedral disease ; the virus has left the nucleus where it develops and has become occluded in the polyhydral crystals surrounding the nuclear membrane. × 10,000

Fig. 2. Similar section to Fig. 1 showing peculiar virus inclusions in the blood cell. × 49,000

difficulties and it became necessary to find another substrate. Carbon films[12] made by boiling carbon in a vacuum have proved very satisfactory ; they have virtually no structure to confuse the issue at high magnifications, and they are more resistant to the electron beam and do not volatilize and foul the gun.

Carbon Replicas

Several replica techniques have been devised since the electron microscope became a laboratory tool, but except for specialized work the carbon replica has proved the most successful. This technique was first suggested by Mühlethaler, but has been brought to its present high standard by Bradley, working at the A.E.I. Research Laboratory at Aldermaston. The carbon replica technique is a single-stage process in which the suspension of material to be replicated is dried down on to a 'Formvar'-coated grid. This is coated with carbon from a source normal to the grid surface and the material removed. The source of carbon consists of two pointed carbons, spring-loaded and touching at the points. A heavy current is then passed across and a spot temperature of 2,000° C. is reached ; the carbon boils and a thin coating of structureless carbon is deposited on the grid. The 'Formvar' and material are then removed by their respective solvents (Fig. 3).

This technique has been applied in various fields and a resolution of 7 A. has been obtained.

Freeze Drying

The most serious source of structural deformation in biological specimens is the force of surface tension, and attempts have been made to adapt the old-established technique of freeze drying to electron microscopy. Two methods are current, one devised by Anderson[13] and the other by Williams[14].

Anderson's technique avoids surface tension forces by drying out in liquid carbon dioxide. The specimen is fixed in osmic acid vapour, dehydrated and finally obtained in a suspension with amyl acetate. The amyl acetate is washed out with liquid carbon dioxide under 30° C. The temperature is raised through the critical point of carbon dioxide (31° C.) and pressure released. This method suffers from the fact that changes in the specimen have been brought about by the introduction of solvents.

Williams's method is more suited for general work. A suspension of the liquid is sprayed on to a carbon-coated copper disk held at the temperature of liquid nitrogen. The disk is put in a vacuum, the temperature raised to −50° C., and the ice allowed to sublime. The carbon film is removed and placed on specimen grids ready for examination.

By the application of these modern techniques to the electron microscopy of viruses, it is now possible to obtain information on the following aspects: (1) size and shape of virus particles; (2) topography of virus particles; (3) surface detail; (4) internal structure; (5) methods of replication; (6) behaviour of viruses in the cell; (7) virus crystals; (8) latent viruses.

Size and Shape

Since little internal structure is visible in whole virus particles, most of the information on their size and shape has been obtained from shadowed specimens. Variations in size and shape are considerable; as we have already seen, some of the plant viruses are rod-shaped, that of tobacco mosaic virus measures 15 mμ × 300 mμ. Other rod-shaped plant viruses include potato viruses *X* and *Y* and a number of soil-borne viruses, some of which are latent in their plant hosts.

Many plant viruses are spherical or nearly spherical, and are very small; examples are the viruses of tomato bushy stunt, Southern bean mosaic, turnip yellow mosaic, tobacco ringspot and squash mosaic, all of which range in size from 30 to 27 mμ. These very small viruses are extremely uniform in size and shape and so are easily obtained in crystalline form. While the majority of the viruses affecting animals and the higher plants are either rod-shaped or nearly spherical, a number of the bacterial viruses are tadpole- or sperm-shaped with a 'head' and a 'tail'.

Air-dried preparations of virus particles in the electron microscope are apt to show distortion and appear smaller than they actually are. Accurate estimation of size, therefore, can only be made on frozen-dried specimens.

Topography of Virus Particles

It was suggested by Crick and Watson[15] that all small viruses are built up on a framework of identical protein sub-units packed together in a regular manner. They showed that three types of symmetry are possible for spherical viruses, namely, tetrahedral, octahedral and icosahedral.

Although many of the smaller viruses present a polyhedral appearance, it requires a combination of the freeze-drying and double-shadowing techniques to give the three-dimensional shape of the particle. A good example of this is provided by the *Tipula* iridescent virus, which even in air-dried specimens presents an almost perfect hexagon or pentagon. Although this virus is rather large, it exhibits such extreme uniformity of size that it easily crystallizes.

It has been shown by Williams and Smith[16] that the particle of this virus is an icosahedron with twenty sides. A cardboard model of an icosahedron was made and shadowed by two light-sources separated 60° in azimuth and orientated so that an apex of the hexagonal contour points directly towards each light source. Under these conditions two shadows are thrown: one has five sides and is blunt-ended and the other has four sides and is sharp-ended. When a frozen-dried particle of *Tipula* iridescent virus is treated similarly, two shadows identical with those thrown by the model are produced. By means of this shadow-analysis, it is proved that the *Tipula* iridescent virus particle is an icosahedron.

Surface Detail

Until recently the amount of external structure of virus particles which could be seen on the electron microscope was somewhat disappointing. It was not possible, for example, to make out the helical structure of the tobacco mosaic virus rod as revealed by X-ray studies. The new staining methods, however, especially negative staining with phosphotungstic acid[17], have given much improved results. By this means the arrangement of the protein sub-units of the virus particle can be visualized directly on the microscope.

Particles of adenovirus, type 5, have been examined in this way. At high magnification the particle has a roughly hexagonal outline and is clearly facetted, each facet being an equilateral triangle with a side consisting of six sub-units. The presence of triangular facets immediately excludes a dodecahedral form and suggests that the particle is an icosahedron. A model of an icosahedron with a side of six sub-units was built from table-tennis balls, and the arrangements of the sub-units in the virus particle and the model are identical. Herpes virus shows a similar sub-unit structure, but the sub-units appear to be hollow and ring-shaped[18].

The same technique has been applied to one of the bacterial viruses, φ*X*174, which apparently has a nearly spherical shape without the 'head' and 'tail' of the *T*-even 'phages[19]. The micrographs of this 'phage suggest that it contains a shell of twelve 'knobs' arranged regularly as on the faces of a regular dodecahedron. This is based on the observation of one apical and five surrounding peripheral knobs with the suggestion of a second underlying tier similarly arranged.

It has been suggested by Klug, Finch and Franklin[20] from X-ray data that the particle of turnip yellow mosaic virus is a snub dodecahedron made up from sixty spherical sub-units. Electron micrographs of this very small plant virus by Brenner and Horne using negative phosphotungstic acid staining show the presence of a number of sub-units.

A characteristic of the insect viruses is the presence of membranes surrounding the virus itself and the various ancillary structures associated with them.

In the early stages of infection with one insect virus, the *Tipula* iridescent virus, there occur many empty shells, the significance of which is discussed later. By means of phosphotungstic acid staining these shells appear to consist of a double membrane, two concentric hexagons. In addition, by negative phosphotungstic acid staining, protein sub-units on the surface of the full or apparently mature virus particles become visible.

Internal Structure

Improvements in the technique of cutting ultra-thin sections not only allow sections to be cut of the virus particle itself but also of serial sections through one particle. This obviously is one way of examining the internal structure of the virus, but the difficulty here is that the electron microscope cannot differentiate between the chemical constituents of the virus. Sections do, however, reveal differences in structure and quantities of contents and, as we shall see, show up the empty virus particles.

Another method is to treat the virus particles with enzymes which dissolve away the protein covering and leave behind the nucleoprotein.

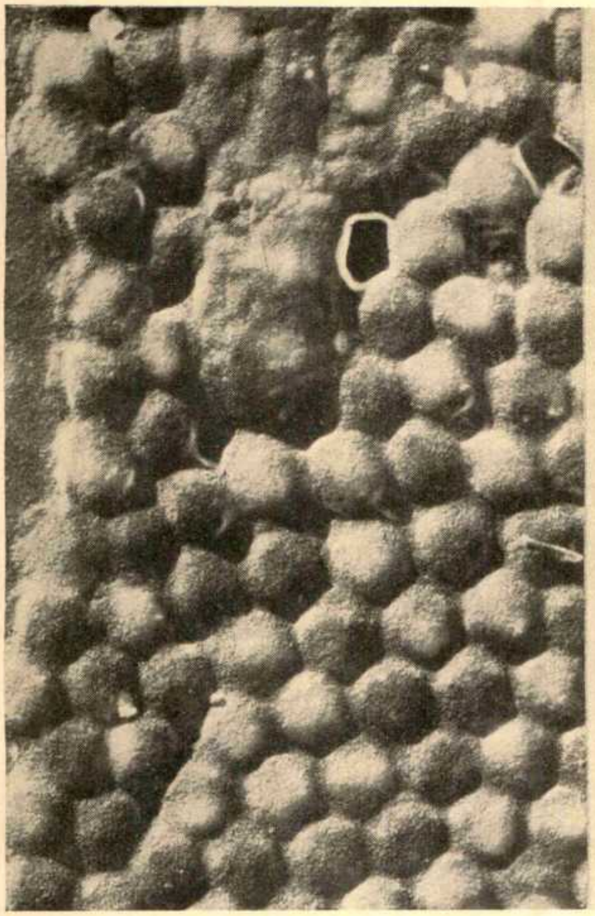

Fig. 3

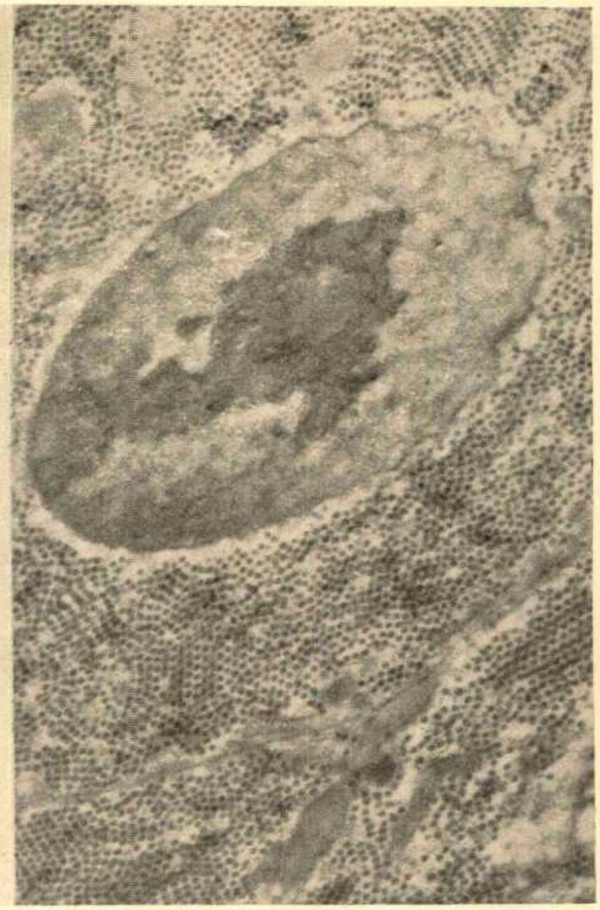

Fig. 4

Fig. 3. Carbon replica of an air-dried microcrystal of the *Tipula* iridescent virus. × 70,000

Fig. 4. Ultra-thin section of fat-body from a larva of *Tipula paludosa* infected with the iridescent virus; note how the virus avoids the nucleus and how the particles are orientated in regular array. × 10,000

Electron micrographs Figs. 1–4 by G. J. Hills

For studying the internal structure of virus particles by ultra-thin sectioning it is, of course, better to choose the larger viruses, although this technique, using a diamond knife, has been applied to tobacco mosaic virus[21].

Ultra-thin sections of vaccinia and fowl-pox viruses reveal a limiting membrane, a dense eccentrically placed body and a finely granular matrix. Sections of these viruses at a later stage seem to reveal developmental changes in which an elongated body surrounded by dense material can be seen[22].

Thin sections of the *Tipula* iridescent virus reveal a variety of different forms ranging from apparently empty shells to the mature virus with its two concentric hexagons.

The rickettsiæ, which strictly speaking should not be regarded as true viruses, are very suitable for this type of study. Thin sections of purified *Rickettsia burnetii* reveal a limiting membrane within which lie a granular region and a dense central body. The configuration of the central body suggests that it may consist of an elongated and irregularly twisted strand[23].

The method of digesting the protein covering and observing the residue by means of the electron microscope has only been applied to the larger viruses. When the influenza virus was treated on the microscope grid with various enzymes, the nucleoprotein component was left behind in the form of an irregular ring built of long threads. A similar result has been obtained with the virus of Newcastle disease of fowls, and when stained with phosphotungstic acid the ring showed a number of dark lines, possibly representing the tracks along the protein to which the long nucleic acid molecule is bound[24].

Methods of Replication

The way in which viruses reproduce themselves has always been a subject of great interest and it is only recently that definite information on this subject has been obtained. Although we know that they do not grow and divide but replicate themselves from their genetic material, it is probable that the method of replication is not the same for all viruses. The most precise information has been obtained on the multiplication of the *T*-even 'phages, and their method of replication is closely bound up with their possession of a 'head' and 'tail'. The 'phage particle attaches itself to the bacterial cell wall which it penetrates and the deoxyribonucleic acid contents of the head pass down into the bacterium[25]. What happens next has been well shown by Kellenberger *et al.*[11]. They used a 1 per cent osmic acid fixative dissolved in acetate veronal buffer, stained their preparations with uranyl acetate and embedded for sectioning in 'Vestopal *W*'. In an infection of *Escherichia coli* by T_2 'phage, the breakdown of the bacterial nucleus is accompanied by the formation of marginal vacuoles containing deoxyribonucleic acid, from which the pool of 'phage deoxyribonucleic acid develops some minutes later. The phage deoxyribonucleic acid starts to increase 6–7 min. after infection. Then, about 9 min. after infection, the protein precursors, immature 'phages and finally, at 13 min., complete 'phage particles appear in the infected cell.

Ultra-thin sections of the fat-body of a larva of *Tipula paludosa* infected with the iridescent virus in an early stage of the disease reveal few virus particles but large numbers of empty or partially empty shells. Some of these membranes contain a few threads, others a central body which varies in size from a small granule to a darkly staining mass filling the membrane. It has been suggested that these empty membranes may represent a stage in the development of the virus ; the assumption being that the membranes form first and the nucleoprotein is afterwards introduced into the empty shell. In sections fixed in formalin it is possible to see the membranes apparently being formed from the substrate.

Behaviour of Viruses in the Cell

The technique of ultra-thin sectioning has allowed the virus to be observed *in situ* in the cell, and a good deal of information on its behaviour has been obtained. Perhaps the least successful in this direction have been the studies of viruses in plant cells. This is partly due to the difficulty in distinguishing between the virus and the normal cell constituents and is particularly true of the very small plant viruses. It occasionally happens, however, that the virus may be concentrated in a small area and then becomes easily visible. In ultra-thin sections of *Datura stramonium* infected with tomato bushy stunt virus, micro-crystals of the virus may sometimes be seen.

It is much easier to observe the animal viruses in the cells, particularly when grown in tissue culture. Certain insect viruses, too, are very suitable for observation in thin sections of infected tissue.

It was shown by Morgan *et al.*[26], by means of sections of chorioallantoic membrane cells infected with herpes virus, that the virus differs slightly according to whether it is in the cytoplasm or the nucleus of the cell. The intracellular cytoplasmic particles consist of a dense central body, surrounded by a double membrane. In the nucleus, however, the particles contained the same central body but only one membrane.

The rate of development of herpes virus has been followed in cultures of HeLa cells. Samples of cells exposed to heavy infection were sectioned and examined for virus at successive time intervals after infection. No increase in infective virus was found in the cultures at 9 hr., but at 12 hr. new virus appeared in the cell fraction and particles were found in the nuclei of two of twenty-five cells. At 26 hr. after infection and later, large numbers of virus particles were present in both nucleus and cytoplasm and on the cell surface[27].

Sections of fat-body from the larvæ of the fly *Tipula paludosa* infected with the iridescent virus reveal enormous quantities of virus in the cytoplasm of the cell but never in the nucleus. The concentration of the virus is such that it forms liquid crystals in the living insect, giving rise to a characteristic blue or violet iridescence (Fig. 4).

Another virus found attacking the same fly larva causes a polyhedral disease, so-called because of the polyhedral bodies which develop in the tissues and which contain the virus. They are protein crystals, not virus crystals. In this disease the virus develops in the nucleus of the blood cells and not, like the foregoing, in the cytoplasm. The virus particles are rod-shaped and are enclosed in a membrane. After formation in the nucleus, the virus rods become occluded in the polyhedra, which lie on the outside of the nuclear membrane (Fig. 1).

Virus Crystals

Because of their small size and great uniformity, a number of viruses have been obtained in crystalline form. This is particularly true of the plant viruses, and examples are those of tomato bushy stunt, tobacco necrosis, turnip yellow mosaic, Southern bean mosaic and others. The crystals of tobacco necrosis virus are very suitable for electron microscopy because of their flat shape and resistance to the electron beam. Replicas of these crystals show clearly the orientation of the virus particles in the crystalline lattice.

After the crystallization of the plant viruses, the production of some animal viruses in the crystalline state passed without much comment. The first of these viruses to be crystallized was that of poliomyelitis and the next the *Tipula* iridescent virus. Crystalline inclusions of herpes virus and adenovirus have also been observed[22]. The crystal structure of *Tipula* iridescent virus is face-centred cubic with the particles held at a distance apart by long-range forces. These crystals show Bragg reflexions of visible light and are responsible for the blue or violet colour of infected larvæ.

We have seen already that many of the small viruses are polyhedral in shape. Electron micrographs of replicas of a plane surface cut through the interior of a single crystal of poliomyelitis virus show this very well[28].

Latent Viruses

Latent infection is an interesting phenomenon which occurs commonly. It is frequently met with in plants and even more frequently in insects, while so many new viruses have been discovered in the excretions of man and monkey that they are known as 'viruses in search of a disease'.

On the whole, attempts to visualize latent viruses *in situ* on the electron microscope have been disappointing, though rod-shaped particles have been observed in healthy plants.

It does not seem possible to stimulate a truly latent plant virus into activity ; it is necessary to inoculate it into another host in order to produce a disease. This, however, does not apply to latent virus infection in insects, which can be 'triggered off' in a variety of ways. This phenomenon has been well demonstrated during cross-inoculation studies. It frequently happens that larvæ, which have been inoculated with a foreign virus, die of a virus disease. Examination, however, may show that the virus which killed the larva was not the one injected but a latent infection stimulated by the foreign virus. This phenomenon has interesting repercussions, because it may be used to obtain new viruses from insect orders in which no virus disease has been recorded For example, until recently no virus had ever been found in the order Neuroptera, but now two or more have been discovered in the carnivorous larvæ of *Chrysopa* and *Hemerobius*, better known as 'lacewing flies' or 'golden eyes' Their predacious larvæ live mainly on aphids but can be induced to feed on pieces of caterpillar infected with a polyhedral virus disease A fairly high percentage of the larvæ that do this die about ten days later from a very similar polyhedral disease (Sidor, C, unpublished work, see also ref 29)

It has long been an axiom that insect viruses were very specific and that transmission to other species did not occur or only rarely did so Experiments to test the truth of this were difficult, owing to the complication of latent infection referred to above However, this difficulty has been overcome with the discovery of the *Tipula* iridescent virus; this gives the opportunity of repeating the cross-transmission studies in a way that avoids the possibility of confusing latency with transmission It is unique in the sense that from an infected insect the virus can be isolated in the form of a brilliant iridescent pellet No other known insect virus has this property, and so *Tipula* iridescent virus can be used as a marker and identified with certainty With this virus it has been possible not only to infect a number of very different fly larvæ but also to transmit the virus back and forth between three different orders, the Diptera, Lepidoptera and Coleoptera[30]

COMPARATIVE STUDIES OF ULTRASTRUCTURE IN BIOLOGY

THE success with which the electron microscope has been used in biological research during the present decade was usefully brought to the attention of a wide variety of biologists by the Linnæan Society of London when it organized a one-day symposium entitled "Comparative Studies in Ultrastructure", held in the British Museum on April 24

Presenting his paper, "Microsomes and Ribonucleoprotein Particles", Dr G E Palade (Rockefeller Institute, New York) began by surveying the research which set the stage for one of the outstanding achievements of electron microscopy, the identification of certain small particles in the cytoplasm of cells of many different kinds as the sites at which one of the steps in protein synthesis is very probably carried out The advances in the techniques of specimen preparation which made this possible, and had also benefited the other investigations discussed in this symposium, were in several instances due to work carried out at the Rockefeller Institute

At the time when electron microscopy began to be applied to the problems of cell growth and the manufacture of secretory products by cells, it was believed that ribonucleic acid was intimately concerned It was also known that the sites of this substance in the cytoplasm were basophilic, and that microsomes (one of the cell components isolated by fractionation procedures) were rich in ribonucleic acid Dr Keith Porter and Dr Palade and their colleagues then discovered the submicroscopic 'endoplasmic reticulum' in the intact cell, identified it with the basophilic material seen in the light microscope and showed that the microsomes were derived from it Palade observed that the membranes of the reticulum often, but not always, carried numerous small dense particles, about 150 A in diameter Using electron optical and biochemical techniques in parallel, Palade and Siekevitz demonstrated that these small particles were rich in ribonucleic acid and that the basophilia of cytoplasm and the ribonucleic acid content of microsomes were due to these ribonucleoprotein particles and not to the membranes of the reticulum But not all the particles are attached to the membranes, many lie 'free' in the cytoplasm

Meanwhile, it had been shown by other workers that microsome preparations could incorporate labelled amino-acids into their proteins Palade and Siekevitz have recently studied the synthesis of chymotrypsinogen and trypsinogen and the turnover of ribonucleic acid in pancreatic cells Various cell fractions (microsome-attached ribonucleoprotein particles, 'free' ribonucleoprotein particles, 'soluble' ribonucleic acid, etc) have been separated and their radioactive isotope and enzyme contents measured The results clearly implicate the ribonucleoprotein particles in enzyme manufacture and suggest that their role may be to arrange activated amino-acids in specific sequences in the polypeptide chains of the proteins they are synthesizing.

The recent technical advances in the preparation of tissues for electron optical studies were admirably illustrated in a paper on "The Fine Structure of Vertebrate Neurons and Their Processes" by Dr. S. A. Palay (U.S. National Institutes of Health, Bethesda). He gave a detailed description of the neuron and brought out the subtle differences in structure between axons and dendrites on which depend the interpretation of the very complex pictures seen in electron micrographs of brain sections. Thus, dendrites contain large numbers of long tubules, about 200 A. in diameter, and clumps of Nissl substance, that is to say, endoplasmic reticulum bearing ribonucleoprotein particles. Axons, on the other hand, are distinguished by large numbers of neurofilaments, about 100 A. in diameter; Nissl substance is absent. These neurofilaments have approximately the same dimensions as the fibrous-protein molecules isolated by Maxwell and his colleagues from the axoplasm of the giant nerve-fibres of squid. Dr. Palay attributed the positive birefringence of axoplasm to the neurofilaments because he found that this optical property is enhanced by lipid extraction.

Among other features discussed in this paper was the structure of synapses, characterized by the increased density of the apposed cell membranes and by the presence of numerous small granules on the presynaptic side, together with mitochondria and elements of the endoplasmic reticulum.

During the past few years evidence has been brought together from several sources to show that cross-striated myofibrils are made up of a longitudinal series of alternating arrays of myosin and actin filaments, giving rise to the *A* and *I* bands; furthermore, that these arrays partly overlap in the *A* bands, and slide into or out of each other as the muscle changes its length, the protein filaments themselves staying at constant length. This evidence has led to the sliding filament hypothesis of muscular contraction, which is based on biochemical and physiological as well as structural information. The hypothesis has received strong support from the results of electron microscopy, which have revealed the spatial relationships of the two kinds of filaments and shown the existence of cross-bridges between them. This work (by H. E. Huxley) and information obtained by Hanson and Huxley by different methods (which confirm and extend the interpretation of the electron micrographs) were reviewed in a paper entitled "Comparative Studies in the Contractile Structures of Striated and Smooth Muscles", by J. Hanson, H. E. Huxley and J. Lowy (Medical Research Council, King's College and University College, London).

The sliding filament hypothesis was based on studies of vertebrate skeletal muscles, and until recently too little was known about smooth muscles, or about any other contractile system, for one to be able to say whether or not a sliding filament mechanism is a special property of striated muscles. But Hanson and Lowy have now found that in three different types of smooth muscles (the byssus retractors of the mussel *Mytilus*, the translucent part of the adductor of the oyster, and the funnel retractor and mantle muscles of the squid) the contractile apparatus consists of two kinds of filaments linked by bridges which resemble those seen in electron micrographs of cross-striated muscles. In all these smooth muscles one kind of filament is about 50 A. in diameter, like the actin filaments of striated muscles. The other kind of filament is thicker, the diameter varying from one type of muscle to another. In the case of the *Mytilus* byssus retractors, a comparison of extended and contracted muscles, cut transversely, has shown that neither the diameters of the thicker filaments nor their numbers (in unit area) change as a result of length changes in the muscle. These findings indicate that the thicker filaments are discontinuous along the fibre and do *not* contract. Such electron optical evidence (together with certain results from X-ray diffraction and light microscopy) strongly suggests that these smooth molluscan muscles contract by a sliding filament mechanism. (However, the smooth muscles of vertebrates, of which Mrs. C. Schoenberg showed some electron micrographs in the discussion following this paper, apparently possess only one kind of filament, about 50 A. in diameter, and no bridges have yet been seen.)

The rest of the paper dealt with work done by Hanson and Lowy on the structure of several molluscan muscles which show various degrees of tonicity, that is to say, the ability to maintain a steady high level of tension for prolonged periods of time. These comparative structural investigations have been carried out in parallel with experimental studies on the mechanical properties of the muscles.

It has been found that the more tonic a muscle is, the longer tension persists after stimulation has ended and the active state has decayed to zero. Thus, in the tonic anterior byssus retractor of *Mytilus*, the decay of tension can be two orders of magnitude slower than that of the active state, whereas in non-tonic muscles like the frog sartorius, or the smooth funnel retractor of *Octopus*, the time scales of the two processes are of the same order of magnitude.

Electron optical studies show that muscles such as the funnel retractors of cephalopods contain well-differentiated myofibrils and sarcoplasmic reticulum, and that their filaments are regularly packed and of relatively small diameter (about 100 A. and 50 A.). In these features such muscles resemble vertebrate skeletal muscles, the chief differences being the absence of *Z* lines and of any alignment of the two kinds of filaments into transverse arrays. At the other extreme, in a specialized tonic muscle like the anterior byssus retractor of *Mytilus*, the filaments are not grouped into fibrils, but are irregularly packed, and they vary greatly in diameter, the thicker ones (that is to say, those which are not of the 50 A. kind) ranging from about 150 A. up to more than 1000 A. In addition, such tonic muscles are distinguished by the fine structure of their thicker filaments. This structure has been found to be due to the presence of large amounts of tropomyosin. The problem now is to show if, and how, tropomyosin is involved in the mechanism responsible for the tonic specialization of smooth muscles, which contract similarly to non-tonic muscles by a sliding filament mechanism.

One of the classical problems of muscle physiology, namely, the means by which the excitatory stimulus reaches the contractile elements inside a muscle fibre, has been brought a step nearer solution by the application of electron microscopy. Several earlier light microscopists described transversely-orientated structures (as distinct from the longitudinal myofibrils and their bands) in striated muscle, and already in 1881 Retzius had suggested that these structures were involved in excitation. The greater resolution of the electron microscope has made possible a more detailed study of these structures, which are now known as the 'sarcoplasmic reticulum' The recent work of A F Huxley (Cambridge) and his colleagues goes a long way towards showing that this reticulum, or probably one particular part of it, is somehow concerned in conducting the excitatory stimulus

In a paper entitled "Comparative Study of the Activation of Contraction in Muscle", Huxley described how isolated muscle fibres were viewed in an interference microscope or in a polarizing microscope, while the potential difference across the surface membrane was changed over a very small area by passing current through a micropipette in contact with the membrane It was found that excitation was conducted transversely (inwards into the fibre) only when current was applied at the levels of the *Z* lines in frog fibres, and near the *A* *I* boundaries in crab and lizard fibres But responses were not obtained everywhere as the micropipette was moved around the perimeter of the fibre at these levels, instead it was found that the sensitivity was limited to definite small areas Stimulation at these places resulted in local contractions which extended into the fibre for a distance several times greater than the length of the sarcomere, but did not spread longitudinally into adjacent sarcomeres Effective stimulation in the frog fibre always resulted in an equal shortening of both halves of the *I* band, the *Z* line remaining central, but in lizard or crab fibres it was possible to cause the *Z* line to move towards one *A* band, its distance from the other *A* band usually increasing as this half of the *I* band was actually stretched All these results were elegantly and convincingly demonstrated in ciné films

The location of the sensitive regions near the *A* *I* boundary in crab and lizard fibres, and the finding that only one half of the sarcomere shortens, suggest that the *Z* line cannot be the structure concerned in conducting excitation Instead, it is probable that certain differentiated elements of the sarcoplasmic reticulum—the 'triads' first described by Porter and Palade—are involved, because as Huxley showed in electron micrographs, these 'triads' are located at the *Z* line level in frog fibres, and near the *A* *I* boundary in lizard fibres

As the title shows, the symposium was planned to emphasize the value of the comparative approach to biological problems The papers on muscle illustrated two successful applications of this the identification of structures concerned with a given function (for example, transmission of stimulation into a muscle fibre) by comparing systems where these functions are differently located, and the recognition of fundamental properties (for example, the structural features which are common to all kinds of contractile systems) by comparing muscles specialized in different ways Similarly, a comparison of different kinds of cells, particularly mammalian, which vary in the intensity and distribution of cytoplasmic basophilia, helped to locate ribonucleic acid at the sub-microscopic level Also the importance of getting away from stock laboratory animals and looking for other more suitable experimental material was brought out by the notable success of Dr Palay in preparing the central nervous system for examination in the electron microscope he chose to work on goldfish However, the only papers which dealt with invertebrate animals were those on muscles, and it was disappointing that in none of the papers was there any mention of plant cells

J Lowy

NEWS and VIEWS

Thermo-Nuclear Physics at Sydney

Prof C N Watson-Munro, O B E

Mr C N Watson-Munro has been appointed, as from January 1, 1960, to the chair of physics in the field of thermo-nuclear physics in the School of Physics, at the University of Sydney The chair normally will be vacant on the retirement of Prof V A Bailey at the end of 1960, but provision has been made for the earlier filling of the chair Mr Watson-Munro was born at Dunedin, New Zealand, in 1915 He graduated at Victoria University College, Wellington, with first-class honours, winning the Sir George Grey scholarship and later a Jacob Joseph scholarship for postgraduate research In 1935 he joined the Department of Scientific and Industrial Research, New Zealand, where he carried out original work on problems of seismology and geophysics at the Dominion Physical Laboratory In 1939 he joined a team engaged on radar development of which he became the leader In 1941 he went to the United States and worked on radar research at the Massachusetts Institute of Technology before establishing the first New Zealand Scientific Liaison Office in Washington in 1942 Later that year he returned to New Zealand to become the director of the New Zealand Radar Development Laboratory Early in 1944 he was specially invited to join the Atomic Energy Research Project at the Chalk River Laboratories in Canada under the direction of Sir John Cockcroft He was largely responsible for the design and operation of the first power heavy-water pile to be built Transferring in 1946 to the Atomic Energy Research Establishment, Harwell, he was, as principal scientific officer, in charge of the team responsible for the design, construction, and operation of Britain's first atomic pile, *Gleep*, a low-power graphite pile that was constructed in fifteen months and has proved very successful He returned to New Zealand in 1948 to take charge of the Department of Scientific and Industrial Research Accepting the chair of physics at Victoria University, Wellington, in 1951, Prof Watson-Munro became dean of the science faculty of that University in 1954 In 1955 he was appointed chief scientist of the Australian Atomic Energy Commission responsible for the Lucas Heights Research Establishment which was constructed under his supervision

Theoretical Physics at Sydney

Prof S T Butler

Dr S T Butler has been appointed, as from November 2, 1959, to the chair of physics in the field of theoretical physics in the School of Physics, at the University of Sydney This is a newly created chair

Dr Butler first studied at the University of Adelaide and graduated (B Sc) in 1945 with credits in all subjects (physics, pure mathematics and applied mathematics) He obtained his first-class honours degree at Adelaide in 1946, and his M Sc in 1947 This latter was for theoretical work, in collaboration with the Physiology Department at the University of Adelaide, and involved an analysis of the transient responses of electronic equipment being employed in physiological and biological research In 1948 Dr Butler obtained an Australian National University scholarship, and proceeded to the Department of Mathematical Physics at the University of Birmingham, England, to work under the supervision of Prof R E Peierls He remained there until September 1951, obtaining his Ph D from the University of Birmingham in June 1951 In September 1951, Dr Butler took up a position in the Laboratory of Nuclear Studies at Cornell University, where he remained for two years He then returned to Australia first to spend ten months at the Australian National University at Canberra, Australia, and then to take a readership at the University of Sydney Since leaving Birmingham in 1951, Dr Butler has made research contributions in several fields, including the low-temperature problems of liquid helium and superconductivity, and in the field of meson and strange particle physics Most of his work, however, has been in the field of nuclear reactions, not only furthering his original work on stripping reactions, but also as one of the originators of the general field of direct nuclear reactions

Scientific Adviser to the U K High Commissioner in India

Dr H R Ambler, O B E

Dr H R Ambler has been appointed to the newly created post of scientific adviser to the U K High Commissioner in New Delhi In addition to advising the High Commissioner on scientific matters, he will be responsible for furthering the exchange of information between British and Indian scientists Dr Ambler, who is fifty-eight, will hold the rank of senior principal scientific officer in the Department of Scientific and Industrial Research He joined the Government service shortly after he graduated with first-class honours in chemistry at the University of London in 1920 Since then he has held a variety of posts at home and abroad, including seven years in India At present, Dr Ambler is assistant director of the Chemical Inspectorate of the Ministry of Supply at Woolwich Dr Ambler, whose appointment is for three years in the first instance, is taking up his new duties at the end of the year.

Explosives Research and Development at the Ministry of Aviation

Dr. C M Johnson, C B E

The Ministry of Aviation announces that Dr C M Johnson has been appointed director of the Explosives Research and Development Establishment at Waltham Abbey Dr Johnson was born in 1904 and gained his Ph.D. at the University of London in 1927 For the next eleven years he was a lecturer in chemistry at the University of California and the University of Bristol In 1938 he joined the Shell Refining and Marketing Co as research manager, moving in 1948 to the Explosives Research and Development Establishment Since 1954 he has been director of the Materials and Explosives Research and Development Branch

Deputy Director of Air Armament Research :

Mr W H Hill

Mr W H Hill has been appointed deputy director of air armament research He was born in 1915 at Warwick, and gained his degree at the University of Cambridge During 1937–41 he was an assistant lecturer in applied mathematics at the University College of the South West, Exeter In 1941 he joined the Royal Electrical and Mechanical Engineers, and was posted to work with the Ministry of Supply on radar and signals research From 1946 until 1951 he worked at the Army Operational Research Group, where he became general scientific co-ordinator In 1951 he joined the Department of the Scientific Advisor to the Army Council In 1952 he was appointed to the Royal Aircraft Establishment, working on guided weapons, and in 1954 he transferred to the Armament Research and Development Establishment as superintendent of the Weapons Assessment Department

History of Medicine and Pharmacy

A Faculty of the History of Medicine and Pharmacy has been founded under the auspices of the Worshipful Society of Apothecaries of London (which received its Charter from King James I in 1617) Its aim is to foster and extend more general interest in medical history, and to attract the co-operation of general historians, so that work in this field may be co-ordinated with wider historical studies The Society will provide in its ancient hall a central meeting point for historians, and medical and pharmaceutical historical societies In addition to the Gideon de Laune Oration, which will next be delivered by Sir John Charles in April 1960, it has an endowment for two additional lectures which may be delivered in London or elsewhere A research fellowship, generously endowed by the Wellcome Trustees, is held at present by Mr R S Roberts, a professional historian, who is working upon the early organization of the drug trade from the seventeenth century It is proposed to hold occasional symposia, discussions, congresses, and joint meetings with other bodies , invitations to visit sites of medical historical interest have already been received Announcements and reports of meetings will appear in the official organ of the Faculty, *Medical History*, which is published quarterly Ordinary membership of the Faculty is by election Applications for affiliation from student historical, medical or pharmaceutical societies or similar bodies, which should nominate a representative, can also be accepted The inaugural lecture will be given in the Hall of the Society on December 2 by Canon Charles E Raven, on ' Medicine—Mother of the Sciences" Further information can be obtained from the honorary secretary, Dr F N L Poynter, Wellcome Historical Medical Library, Euston Road, London, N W 1

Distribution of British Books and Films Overseas

In reply to a question in the House of Commons on November 9, the Chancellor of the Duchy of Lancaster, Dr Charles Hill, said that negotiations had begun with several countries with the aim of agreeing upon schemes broadly on the lines of the former British book export schemes Mr A L P Norrington had accepted the chairmanship of the Advisory Committee on the Selection of Low-Priced Books for Overseas, and the necessary administrative arrangements were being made so that negotiations on contracts could begin as soon as titles had been selected A Publishing Trade Consultative Panel had been set up after consultation with the trade organizations concerned The British Council was steadily expanding its own library services and co-operating with Colonial Governments in improving their services and there had been consultation with trade organizations in the periodical field on measures to assist circulation of newspapers and periodicals in some of the more difficult markets overseas Consultation was also taking place with the publishing trade in Great Britain and other countries with the view of encouraging more effective wholesaling and retailing of books in the African countries in particular Answering a further question, about documentary films, Dr Hill said that in 1958–59 the Central Office of Information commissioned twenty-eight documentary films and acquired 118, all for overseas distribution, and in 1959–60 it was expected that about 120 would be acquired More than a hundred British films had been entered in 1959 for showing at international festivals and twenty-one awards or special mentions had been gained

National Lending Library for Science and Technology Consultative Committee

A consultative Committee has been appointed to advise the Department of Scientific and Industrial Research on the services of the National Lending Library for Science and Technology Literature is now being collected for the Library by the Lending Library Unit of the Department at 20 Chester Terrace, Regent's Park, London, N W 1 The National Lending Library for Science and Technology will be located near Boston Spa, Yorkshire, and its transfer will take place in the first half of 1961 Its collection of scientific literature, which will become the largest in the United Kingdom, will be available to any organizations through loan and photocopying services

The Committee is as follows · Sir Lindor Brown, biological secretary of the Royal Society (*chairman*), Prof J D Bernal, professor of physics, Birkbeck College, London, Mr D I Colley, librarian, Manchester Public Library, Dr B M Crowther, editor of *Science Abstracts*, Mr G. H Davison, secretary of the United Steel Companies, Ltd, Research Department, Dr R E Fairbairn, head of the Library Department, I C I Dyestuffs Division, and chairman of the Council of Aslib, Mr R M Fishenden, United Kingdom Atomic Energy Research Establishment, Harwell, Prof G Gee, Sir Samuel Hall professor of chemistry, University of Manchester, Mr C W Hanson, research officer, Aslib; Mr L J H Haylor, Ministry of Supply, Mr K W Humphreys, librarian, University of Birmingham, and secretary of the Standing Conference of National and University Libraries; Mr D D Morgan, information manager, P E R A, Prof W J T Morgan, Lister Institute of Preventive Medicine, London, Mr H T Pledge, keeper, Science Museum; Dr M R Pollock, Medical Research Council, Mr A C Townsend, library of the British Museum (Natural History) The secretary of the Committee is Miss R M Bunn

Dounreay Fast Breeder Reactor Critical

The Fast Breeder Reactor at Dounreay went critical on November 14 The reactor will go through a period of low-power operation for some months This may be followed by a shut-down for any modifications found necessary, and the reactor will then be worked up to power in stages Construction work on this reactor started in May 1955 and it was scheduled to start operating last year Because of the redeployment of staff due to the Windscale pile incident and to certain design modifications, start-up has been delayed The reactor consists of a central core which is a hexagonal prism approximately 21 in high and 21 in across the flats This is made up of about 360 enriched uranium rods in niobium cans, and is surrounded by a 'blanket' of 2,000 rods of natural uranium which under irradiation produces plutonium Plutonium can be used in the core to produce more heat and more plutonium, and experiments have shown that the amount of fissile material produced in the core and the blanket during operation will exceed the amount burned up in the core, and the reactor is thus a breeder In this type of reactor the neutrons are not deliberately slowed down as in a thermal reactor, that is, no 'moderator' is used and the neutrons are said to be 'fast' Heat is removed from the core and blanket by a liquid sodium–potassium alloy, which is circulated by electromagnetic pumps through the vessel and through heat exchangers The reactor with its primary heat exchanger circuits is installed in a concrete vault within the 135-ft diameter steel sphere which dominates the Dounreay site In the early stages the Dounreay reactor will be operated to provide information on the physics and control characteristics of this type of system, and this will be followed by a stage of intensive development and testing of different types of fuel elements

South African Council for Scientific and Industrial Research

The thirteenth annual report of the South African Council for Scientific and Industrial Research covers the year ended March 31, 1958, and includes lists of research bursaries and assistantships awarded during the year as well as a list of publications (Pp xvii + 226 + xix–lix Pretoria South African Council for Scientific and Industrial Research, 1958) Concern is expressed as to the shortage of scientists and particularly at the loss overseas of promising South African scientists Much interest is being taken in the work on the demineralization of water by electrodialysis, and the plant designed by the Council and being erected at Welkom has a capacity of 2 5 million gallons a day River surveys involved a comprehensive programme of chemical, biological, bacteriological tests and flow data, as well as laboratory studies on the chemical and biological reactions in water and river mud A Wine Research Unit was established at Stellenbosch, where it is hoped that investigations of the causes of biotic turbidity will offer a solution of a serious problem in South African wines Investigations on the chemical mechanism of carcinogenesis continued Initial difficulties with the cyclotron at the National Physical Laboratory were overcome during the year and improvements in several of the basic components increased the stability of operation The isotope separator was assembled in December 1957, and the electro-mechanical recording systems in South African Courts established by the Acoustics Division were further extended Under a recently established Foundry Sands fellowship the properties of available sands are being studied and their suitability for casting determined At the National Mechanical Engineering Research Institute work was carried out on the phenomenon of rock-bursts with a view of devising methods for their prevention or at least of decreasing their incidence and severity. The Institute is also studying erosion, the silting of rivers and harbours, coal-burning gas turbines and solar operated refrigeration systems.

In telecommunications a radio tracking system was improvised which enabled the orbit of the first Russian Earth satellite to be determined roughly within a few days and an accurate determination of the velocity of radio waves was made by means of extensive measurements at the Ridgeway base and surrounding triangulation to provide a value which can be used confidently in work with 'tellurometers'. Work was carried out on the shear strength of non-saturated soils under different moisture conditions and the stresses set up in various layers of road foundations by compaction operations or surface loads were closely observed. Experimental studies on the relations between malnutrition and the mental development of young children showed that 38 per cent of a group of Bantu children suffering from kwashiorkor had abnormal electroencephalograms compared with only 3 per cent of normal children, and another study showed that rats bred from protein-deficient mothers and themselves reared on protein-deficient diets were inferior in learning ability to those bred and fed normally. In medical research particular attention is being given to the relation between diet and diseases of the arteries.

Waterways and Ionizing Radiations

CIRCULAR No. 57/59 from the Ministry of Housing and Local Government to local authorities, joint water boards, joint sewage boards, river boards, statutory water companies in England and Wales tells them from which departments of the Government they should seek advice when in doubt about local problems concerning hazards from ionizing radiations. As a potted "Inquire Within on Everything" in this field it is extremely informative and helpful. As an explanation of the scientific problems involved it is slipshod, since the construction of the sentences is tortuous, 'radioactivity' is confused with 'radiation' and there is at least one mis-statement attributed to the Medical Research Council on the contribution by diagnostic X-rays to the dose of radiation received by the general population.

Hatfield Memorial Lecture

ACADEMICIAN G. V. KURDJUMOV, director of the Department of Metallography and Metal Physics at the Central Research Institute for Ferrous Metallurgy, Moscow, has accepted an invitation from the Council of the University of Sheffield to deliver the twelfth Hatfield Memorial Lecture, in the Firth Hall of the University on November 25. His subject will be "The Phenomena occurring in Steels during Quenching and Tempering". The Hatfield Lectures, which are given annually in either London or Sheffield, were founded in memory of the late Dr. W. H. Hatfield, and are always devoted to a subject in which Dr. Hatfield was interested. The Hatfield Memorial Lecture Fund is administered by the University of Sheffield as trustees, and arrangements are in the hands of a Lecture Committee, composed of representatives of the University, the Royal Society and the Iron and Steel Institute. Academician Kurdjumov is also to lecture to the Iron and Steel Institute during the autumn general meeting in London. He will be speaking at the Hoare Memorial Hall, Church House, Great Smith Street, S.W.1, on December 2, and on this occasion his subject will be "Martensitic Transformations in Metals and Alloys".

International Federation of Automatic Control

FOLLOWING the first General Assembly in Chicago of the International Federation of Automatic Control, it is announced that the Executive Council now consists of the following members: *President*, A. M. Letov (U.S.S.R.); *Past President*, H. Chestnut (U.S.A.); *First Vice-President*, Ed. Gerecke (Switzerland); *Second Vice-President*, O. Benedikt (Hungary); *Treasurer*, M. Cuénod (Switzerland); *Ordinary Members*, J. G. Balchen (Norway), J. F. Coales (Great Britain), G. Evangelisti (Italy), K. Kaneshige (Japan), P. J. Nowacki (Poland), Z. Trnka (Czechoslovakia). D. P. Eckman (U.S.A.) will remain chairman of the Advisory Committee of which J. Loeb (France) was appointed vice-chairman.

The Vernon Prize

THE late Dr. H. M. Vernon made a bequest to the National Institute of Industrial Psychology expressing the wish that the Institute should award a prize every second year to the investigator who, being a British subject and under the age of forty-five years, has in the opinion of the council of the Institute done the most valuable research work in the service of industrial psychology or industrial physiology. The fourth award will be made in 1960; it will consist of approximately £40 in cash and a silver medal. Recommendations and direct applications must be received by February 29, 1960. Further information can be obtained from the Secretary, National Institute of Industrial Psychology, 14 Welbeck Street, London, W.1.

Royal Agricultural Society of England Research Medal

THE Royal Agricultural Society of England offers annually a Medal together with an award of 100 guineas for research work of outstanding merit carried out in the United Kingdom which has proved, or is likely to prove, of benefit to agriculture. Recommendations for this award can be made by the heads of university departments, research stations and institutes and other research organizations. No direct application by candidates will be considered. Recommendations for the next award must be submitted to the Secretary, Royal Agricultural Society of England, 35 Belgrave Square, London, S.W.1, not later than January 30, 1960, and from whom further information can be obtained.

Course on Digital Computers

THE British Council is arranging a course on digital computers in London during February 7–20 for industrial and research scientists from overseas. The course will concentrate on recent improvements in computer design and programming techniques, and will be closely linked with practical work in industry. Many firms have already offered to show computers being made or actually used for commercial and industrial purposes. Course members will also be able to discuss problems with workers on the job. The course will be directed by Dr. Andrew Booth, head of the Department of Numerical Automation at Birkbeck College. Visits have been arranged to see computing equipment at the National

Physical Laboratory (*Deuce* and *Ace*), Ferranti (*Pegasus* and *Sirius*), Elliot Brothers, Cambridge University Mathematical Laboratory (*Edsac II*), E M I. Electronics (*Emidec*), London University Computational Laboratory (*Mercury*) Creeds (project high-speed punching), Solatron (*Era*), Leo Computers and International Computers and Tabulators The fee for the course is £47 and accommodation will be in London hotels

Radioisotopes in Agricultural Research

A REGIONAL training course on the use of radioisotopes in agricultural research, organized jointly by the Ministry of Food and Agriculture, Government of India, Food and Agriculture Organization, International Atomic Energy Agency and Unesco South Asia Science Co-operation Office, will be held at the Indian Agricultural Research Institute, New Delhi, during January 20–February 17, 1960 The course will deal with the role of radiation in cytology and genetics, radioisotope techniques as applied to problems in soil fertility, fertilizer application and plant biochemistry and radiation as a protective agent Unesco has extended invitations to the Governments of Burma, Ceylon, India, Pakistan and Thailand A maximum of twenty-five participants will be admitted to the course Further information can be obtained from the Unesco South Asia Science Co-operation Office, 21 Curzon Road, New Delhi, India

The Night Sky in December

FULL moon occurs on Dec 15d 04h 49m U T and new moon on Dec 29d 19h 09m The following conjunctions with the Moon take place Dec 2d 06h, Saturn 4° S , Dec 26d 19h, Venus 2° S In addition to these conjunctions with the Moon, Mars is in conjunction with Antares on Dec 15d 16h, Mars being 4 4° N, Mercury with Antares on Dec 20d 08h, Mercury being 6 0° N, Mercury with Mars on Dec 25d 13h, Mercury being 1 0° N, Mercury with Jupiter on Dec 27d 01h, Mercury being 0 0° S, and Mars with Jupiter on Dec 29d 01h, Mars being 0 8° S Mercury will be visible as a morning star during the first three weeks of the month, rising almost two hours before the Sun, but conditions are not particularly favourable Venus is a morning star, rising at 3h 25m, 4h 00m and 4h 40m on December 1, 15 and 31, respectively, its stellar magnitude is −3 8 Its distance increases during the month from 77 to 98 million miles and the visible portion of the apparent disk increases from 0 598 to 0 714 Mars, Jupiter and Saturn are too close to the Sun for observation Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich Dec 13d 22h 10 3m, 75 Tau (*D*), Dec 20d 6h 09 4m, ο Leo (*D*), Dec 20d 7h 12 6m, ο Leo (*R*), Dec 27d 6h 34 1m, θ Lib (*R*), *D* and *R* refer to disappearance and reappearance, respectively The Geminid meteors are active during December 9–14 and the Ursids during December 20–22, but in neither case are conditions favourable for observation The winter solstice occurs on Dec 22d 15h

University News : London

DR G MORTON, lecturer at the London School of Economics and Political Science, has been appointed to the University readership in operational research tenable at that School

Titles have been conferred as follow professor of embryology on Mr Michael Abercrombie, reader in chemistry on Dr D J Millen, reader in botany on Mr P J Syrett, in respect of their posts at University College

Sheffield

THE following appointments to lectureships have been announced E Litton (civil engineering), L G M Sparling (mechanical engineering)

Announcements

THE firm of Blackie and Son, Ltd, has celebrated its 150th year of publishing Until very recently, all the scientific and technical publishing was conducted from Glasgow, but now a publishing department has been set up at the firm's London office to handle this type of book, and Mr Christopher T Rivington has been appointed London scientific editor

MR A S D BARRATT, technical director of Edwards High Vacuum, Ltd, since 1945, is resigning from the board of the Company at the end of the year to become an independent consultant His long association with the Company will, however, be maintained by his appointment as technical consultant to the Company, thus providing a liaison between the large-scale developments of vacuum technology now taking place and the long-term developments of the Edwards international group of companies

THE Iron and Steel Institute is devoting the main sessions at its autumn general meeting during December 2–3 to the forging and extrusion of steel The meeting is being held in the Great Hall, Caxton Hall, London Further information can be obtained from H Cleere, Iron and Steel Institute, 4 Grosvenor Gardens, S W 1

A SYMPOSIUM on the Exploitation of Natural Animal Populations, sponsored by the British Ecological Society, will be held at the Durham Colleges, University of Durham, during March 28–31 Full details can be obtained from E D Le Cren, The Ferry House, Ambleside, Westmorland

THE University of Texas M D Anderson Hospital and Tumour Institute announces the fourteenth Annual Symposium on Fundamental Cancer Research, "Cell Physiology of Neoplasia", to be held during February 25–27 Further information can be obtained from the Editorial Office, The University of Texas M D Anderson Hospital, Texas Medical Center, Houston 25, Texas

THE Department of Civil Engineering and the Department of Extra-Mural Studies in the University of Birmingham have announced a course on River Pollution Sewage Disposal and Trade Waste Treatment, to be held at the University of Birmingham during January 4–8, 1960, and continued during April 4–8, 1960 The course is arranged in co-operation with the Institute of Sewage Purification Further information can be obtained from Mr R F Wills, Civil Engineering Department, The University, Edgbaston, Birmingham 15

FURTHER to the announcement in the September 19 issue of *Nature* regarding the availability of the "Great Soviet Encyclopædia" in Britain, a complete translation into English of the fiftieth volume of the second edition will be published by Pergamon Press, Ltd, early in 1960 under the title of "U S S R Information" This is an authorized translation, produced with the full co-operation of the editor-in-chief of the "Great Soviet Encyclopædia".

CHEMISTRY IN THE EIGHTEENTH CENTURY

AN international meeting was convened in Paris during September 11–13 by the Comité National Francais d'Histoire et de Philosophie des Sciences in the name of its president, Prince Louis de Broglie It was timed to follow on the ninth International Congress on the History of Science, held this summer in Spain, and some of those attending did in fact reach Paris via Barcelona The invited contributors were asked to review topics such as phlogiston, the discovery of the gases, the preparation of non-gaseous chemicals, the reformation in chemistry, affinities, chemical biographies and works, chemistry and eighteenth-century science

Final arrangements were completed by M Maurice Daumas (Conservatoire National des Arts et Métiers) and he proposed to some thirty participants, when they assembled at the Conservatoire, six sessions incorporating twenty-five speakers, who would each be allowed thirty minutes for reading and discussion of their announced memoir This Procrustean principle, genially supervised by the sessional chairman, worked out surprisingly well A provocative précis, giving time for a rapid-fire of terse, ready commentaries in French or English, often threw very helpful flash-lights on an unfamiliar subject

The largest single groups attending were from France and the United States, but a useful British contingent accompanied the representatives of Eastern Germany, Eire, the Soviet Union, Sweden, Switzerland and Yugoslavia Some others, including Douglas McKie, were unable to attend, but this was a notable, perhaps a unique concentration of interest and authority on the history of chemistry

Reference to individual contributions must be invidious It is in any event the intention of the sponsors to publish, under a separate cover, the proceedings of this colloquium These again surveyed such pivotal pillars of progress as Boerhaave, Black, Priestley and Lavoisier If perhaps too little was heard on Henry Cavendish and J B Richter, other figures such as Bergman, Crawford, Cullen, Geoffroi, Kirwan, de Morveau, Scheele, Tillet and Watt were exhibited in refreshing detail

To the minority of professional chemists in attendance, there may have been something a whit rarefied in the attention given to Maupertuis and Gaspard Monge, but these were balanced by the stiffly practical consideration given by Academician Arthur Birembaut to early gas-manipulation or by F Greenaway to contemporary analytical chemistry None surely will forget the calm finality with which G Kersaint buried the unsavoury legend of the treachery of Fourcroy to Lavoisier, Figourovskij straddling the difficulties of language and time in his projection of Lomonossov, Claude Secretan's cool, systematic appraisal of scientific personalities, the charming intervention of M Braise, who now occupies the pharmacist's shop once served by Lavoisier's mentor, Guillaume-Francois Rouelle

The formal sessions were extended to the lunch-table, where the exchangers of criticism, literature-reference and citation could communicate their ideas There was also an exciting inspection of new acquisitions from Lavoisier's laboratory apparatus (By an educative coincidence, Blériot's original biplane apparatus, in this jubilee year, was seen suspended from the ceiling of another room) The foreign guests were permitted a privileged visit to the chemical archives of the Academy, an inspection of note-books by Lavoisier, and a glimpse of the meeting-rooms with their antique velvet, gilt frames, classic mouldings and individual microphones

Personal and renewed impressions were of the countless historical trails that lead back to Newton and Boyle, the accepted importance of the chemistry of the Scottish universities in the eighteenth century, the long-delayed development of Stahlian doctrine in the hands of Macquer and Rouelle, the painstaking, sharp rescrutiny of the contributions by Lavoisier to chemical theory, the muddled yet stimulating notions of affinity, the factors and persons which foreran Dalton An intimidating confusion of early schools and ideas, acquiring a laboured, significant sequence as the simple gases were isolated and understood, and there is still much historical material to arrange and digest before such studies bring full benefit

In their development of chosen themes by address or in debate practically every speaker was mindful of the broader canvas against which the chemical feature must be examined There was careful attention to contemporary physics, metallurgy and pharmacy, to economics and invention; even inevitably to politics, with some good-humoured interventions on delicate French and Irish situations Here were specialists indeed, but specialists determined on an adequate setting of their studies even to "The Fifteen", the Mountain and Vinegar Hill Humanism kept breaking in

Much more than the usual formalities of praise must go to the organization of this conference. Informal, urbane, efficient, friendly, it produced the sadly impractical conviction that such meetings should be held more frequently, and always convened in Paris Of still more lasting importance was the sense of community created Historians of science and especially, one imagines, historians of chemistry must generally plough a somewhat lonely furrow, although there are seemingly a few sites of adequate appraisal and support Here was the refreshment of friendly controversy, of actual and potential collaboration, and an atmosphere in which chemistry was seen as something even more than a magical technique, seen as a major factor in the climactic development of scientific method and modern science, as a bright particular strand in the culture pattern of Western mankind On these last points the eighteenth century had already no doubts at all

In some closing words of appreciation, Henry Guerlac used his graceful bilingualism to express our thankful sense of pleasure and profit from this occasion and hinted at a possible opportunity of meeting American colleagues in 1962 None commented on the very sparse German attendance or on the Italian absences which some later colloquium will surely find improved

ANDREW KENT

FAST CHEMICAL REACTIONS IN SOLUTION

VERY many chemical reactions in solution proceed too rapidly to be studied by conventional techniques, which require times of at least several seconds for their manipulation. Slower reactions often involve several steps, all but one of which are fast. It is also generally true that the simplest and most fundamental reactions tend to be fast ones.

The development of electronic methods of detecting and recording has made it possible to record almost any physical parameter in a very short interval of time and therefore to carry out a chemical investigation. But, in order that such an observation shall be significant, it is necessary to initiate the chemical change in some way in a time which is short compared with the time of reaction. Methods of attaining this and some of the results obtained were the subject of a recent meeting organized by the Bunsengesellschaft für physikalische Chemie and the Max-Planck-Gesellschaft. The colloquium was held in Hahnenklee/Harz during September 14–17 and was attended by about one hundred and sixty scientists, of whom about ninety were from Germany, thirty from the United States, twelve from Britain and twenty-eight from other countries. Thirty papers were presented, covering practically every available method.

The first two days were devoted to a discussion of the fast-reaction methods and measuring techniques themselves. Historically the first method was the rapid-mixing method introduced by Hartridge and Roughton thirty-six years ago, and this was discussed by F. J. W. Roughton (University of Cambridge) with particular reference to the reactions of hæmoglobin, for which the method was first developed. It has been extended and modified in many ways, for example, by the introduction of stopped-flow techniques, and is useful for half-reaction times of about 1 millisecond or more. Flash photolysis, developed by Norrish and Porter, is a second generally useful method, and in describing this method G. Porter (University of Sheffield) pointed out that almost every type of reaction can be initiated photochemically, and that at present it is possible to measure bimolecular reaction-rates with velocity constants up to 10^{10} litres/mole/sec and first-order constants up to 10^{5} sec^{-1}.

Q. H. Gibson (University of Sheffield) described how the stopped-flow method has been used to study the combination of hæmatin and carboxy-hæm with globin. Examples of the application of the flash photolysis method were given by H. Linschitz and J. Eloranta (Brandeis University), who used this method to study metal and hydrocarbon ion solutions, by H. T. Witt, who gave an extensive survey of the work which he and his co-workers have carried out on chlorophyll with particular reference to primary processes of photosynthesis, and also by E. W. Abrahamson (Syracuse University), who described work on the visual pigments.

Both mixing and flash-photolysis methods are applicable to systems which are far removed from equilibrium as well as to relaxation systems. Most of the other fast-reaction methods start with a system at equilibrium, displace the equilibrium slightly by changing some physical parameter and then observe the rate of relaxation to the new equilibrium position. Dr. M. Eigen and his colleagues at the Max Planck Institute for Physical Chemistry in Göttingen have been pioneers in this field, and a comprehensive review of relaxation methods and an account of the mathematical procedure and of the assumptions necessary to evaluate rate constants from the experimentally determined parameters was given by L. De Maeyer. Displacement can be either periodic or of the jump type, and temperature, pressure, field impulse and sound absorption are all used to produce the disturbance. K. Tamm (University of Göttingen) gave a survey of the use of the sonic relaxation method for rate measurements in water solutions. M. Eigen summarized many reactions which have been studied by relaxation methods. The fastest reactions which are controlled by diffusion give rate-constants of about 10^{10} litres/mole-sec for ionic reactions other than protonic where values of about 10^{11} litres/mole/sec are obtained. The use of the ultrasonic technique to study association reactions and rotational isomerizations was outlined by Van W. Maier (University of Freiburg) and J. Lamb (University of London) respectively, and the application of the relaxation method to enzymatic reactions was discussed by R. A. Alberty and G. G. Hammes (University of Wisconsin).

A new and very powerful approach to fast reactions is provided by the methods of electron and nuclear magnetic resonance. A molecule, such as water or hydrogen peroxide with two equivalent protons, gives a single peak in its nuclear magnetic resonance spectrum. A mixture of water and hydrogen peroxide will give two separate peaks if there is no exchange between the protons of the two molecules. However, if there is a fast exchange of the protons, there will be only one peak as all the protons will then appear equivalent. For intermediate cases the exchange-rate constants may be calculated from the form of the spectra. The nuclear magnetic resonance method can be used for reaction times from 1 to 10^{-3} sec. Electron spin resonance spectra can be interpreted in an analogous way to determine reaction-rates with characteristic times in the range 10^{-4} to 10^{-9} sec.

The carbon dioxide – water equilibrium has been studied by A. Patterson and R. Ettinger (Yale University) using nuclear magnetic resonance methods. Patterson pointed out that two most interesting questions remain unanswered, namely, why is such a large proportion of carbon dioxide in solution present in dissolved but not hydrated form, and, secondly, why is the hydration reaction such a slow process. R. G. Pearson (Northwestern University) explained how paramagnetic ions in solution affect the line-shape and how line-width can be used to measure exchange rate constants for reactions of complex ions.

Methods which are not quite so general in their application include the fluorescence method—A. Weller (Technischer Hochschule, Stuttgart) described how it is used to measure the fast reactions of excited molecules—and electrochemical methods. R. Brdicka (University of Prague), Jiri Koryta (Academy of

Science, Prague) and others gave comprehensive reviews on the use of polarographic technique in the study of electrode reactions

The transfer of electronic excitation energy between molecules is a special type of fast reaction which, in some cases, is so efficient that rate constants exceed those calculated for the maximum rate of a diffusion-controlled reaction using normal collision diameters Prof Th Forster (Technischer Hochschule, Stuttgart) explained how the interaction in such cases occurs through dipole–dipole coupling so that energy transfer can take place over distances as great as 50 A Two examples of the direct measurement of energy transfer processes were presented S S Brody (University of Illinois) has used a small specially designed hydrogen lamp to produce a flash of a few millimicroseconds duration He measured the delay between the flash and the fluorescence of chlorophyll in the chloroplast By using suitable filters, other pigments apart from chlorophyll were made to absorb the light and the sensitized fluorescence of chlorophyll was studied M Burton and H Dreeskamp (University of Notre Dame) were also able to resolve decay times of about 10^{-9} sec A low-voltage X-ray tube was used to deliver an approximately square wave pulse of about 10^{-8} sec duration with rise and fall times each about 10^{-9} sec By this means the energy transfer from benzene to *p*-terphenyl was measured

Papers by H Eyring (University of Utah) and R M Noyes (University of Oregon) dealt with questions of solution structure and fast reactions Noyes has developed a simple theory to predict the quantum yield for iodine dissociation from the values of the viscosity of the solvent, the sizes and masses of the fragments of dissociation, the energy of the bond that is broken and the energy of the absorbed quantum The agreement between theory and experiment is remarkably good for such a simple model

A very pleasant feature of the meeting was a visit to the Max Planck Institute in Gottingen, where a number of experiments on fast reactions in solution were demonstrated This visit provided a unique opportunity to compare and contrast many of the methods discussed at the colloquium The methods demonstrated included (1) flow methods, (2) relaxation methods—field impulse, temperature and pressure jump and sound absorption (3) polarographic methods, and (4) the nuclear magnetic resonance method

A lively discussion followed most of the sessions and was greatly facilitated by an excellent earphone translation system between the German and English languages Most of us left the meeting feeling that, with such a wealth of excellent methods available, there is now practically no chemical reaction in which rate cannot be directly measured, and the 'instantaneous reaction' has gone for ever It was also clear that reactions which proceed in times of less than one second are as numerous and at least as fundamentally important as those which allow a more leisurely approach to rate measurement

G PORTER
F WILKINSON

SWISS SOCIETY FOR NATURAL SCIENCES

THE one hundred and thirty-ninth annual meeting of the Swiss Society for Natural Sciences was held at Lausanne during September 11–13. The annual president, Prof A Girardet (Lausanne), opened it, with an address on "La science, le savant et le pharmacien", touching the history and psychology of pharmaceutical teaching, practice and research, which in Switzerland are the concern of the universities and medical authorities far more closely than in Britain in the general pattern of scientific and industrial development He pointed out in conclusion the financial handicap implied by the present-day loss of monopoly for the sale of many types of drugs, which has forced the pharmacist to extend his business to non-pharmaceutical products to the detriment of his professional standing Once the equals of the surgeon in the employ of the medical theorist, the pharmacist and pharmacologist have not fought their way to the same independence and supremacy as he has

The first general meeting adjourned to St Croix in the Jura Mountains, a geological and industrial district of considerable interest, in magnificent weather enjoyed with mixed feelings by the inhabitants, entirely dependent on wells for their water Prof A de Muralt (Berne) reported on the first seven years of the Swiss National Fund for Scientific Research, State subsidized but remarkably free from State control, and available to Swiss organizations and individuals in the widest conceivable manner Nuclear research has naturally come in for a large share, and its potentialities and limitations in Switzerland were discussed separately in more detail by Prof P Huber (Basle), who has been most concerned with it

The remainder of the general proceedings took place in the fine painted Aula of the University of Lausanne, adjoining the magnificently re-organized up-to-date library and the Museum of Fine Arts, where one of the hospitable receptions was held, all of them pleasantly devoid of any visible host or formality of any kind

After an illuminating account by P Muller, of the Paris Observatory, on "Le Pourquoi des Satellites Artificiels", and a masterly and moving survey, "La Science à la Recherche d'une Conscience", by the annual vice-president, Prof D Rivier (Lausanne), the day ended with a report by Dr G Chevallaz (syndic of Lausanne) on preparations in hand for the Swiss National Exhibition to be held in 1964 at Lausanne in better circumstances, it is to be hoped, than its predecessors of 1914 in Berne and 1939 in Zurich

Finally, at the third general meeting, Dr F Kaudewitz, of the Max Planck Institute of Tubingen, spoke on "Methoden, Denkweise und Ergebnisse der Erbforschung an Bakterien", with a sober simplicity, clarity and directness remarkable in so new and complex a domain, and the *sous-directeur* of the National Museum of Natural History at Paris, T Dorst, under the title "La Signification des Galapagos pour l'Étude de l'Évolution", gave the latest findings and hypotheses on these unique islands

The meeting was timed to coincide with the annual Comptoir Suisse at Lausanne, in order to give Swiss residents the advantage of return travel at single fare by means of an automatic ticket-stamping device inside the Comptoir, with a reduced entrance fee for members of the Society The simultaneous disadvantage that hotels had to be booked long in advance kept away a certain number of members Nevertheless, the sectional proceedings were on the whole as lively and well attended as ever, the Geophysical, Meteorological and Astronomical Section in particular being fortunate in having the director of the Swiss Meteorological Station, Prof J Lugeon, at hand in person after his extensive travels of recent years, partly in connexion with the International Geophysical Year and two of them to the North Pole, to report, with collaborators, on "Les Recoupements Radiogoniographiques des Grands Foyers Orageux de l'Hémisphere Nord depuis la Base Spitzberg-Suisse (4100 km)" and "Comparaison des Régimes des Parasites Atmosphériques Polaires et Européens", and to give a preliminary report on measurements of atmospheric electricity and radioactivity of the air at Murchison Bay during the International Geophysical Year The History Section was specially interesting with reports on the mathematical aspect of the Hippocratic Logos (Dr Lichtentaeler, of Leysin), on Baldasar Heseler's eyewitness account of Vesalius's first public anatomy lecture at Bologna in 1540 (Dr N Mani, of Basle) and on the little-known mathematician and philosopher de Crousaz, of Lausanne, 1663–1750 (Dr Ed Fueter, of Wadenswil, ZH) Perhaps the Physics Section was the busiest, under the annual vice-president, Prof D Rivier, with twenty-eight papers mainly on metal, crystal and atomic physics

Excursions after the meeting were organized for those interested in geology (3 days), mineralogy (2 days) and botany (2 days)

R C H Tanner

SCIENCE AND THE LIBRARY SERVICES IN BRITAIN

THE programme of the annual conference of the Library Association usually includes two or three papers of some general scientific interest and, although that of the annual conference held at Torquay during September 22–25 was possibly of less scientific interest than usual, Prof Lancelot Hogben's "Past, Present and Future of the Printed Page", Sir Sydney Roberts's "Reflections on the Roberts' Report", and Alderman F J Stott's "The Public Library as a Major Instrument of Education" are of wide interest Besides this, Miss M E Wilden-Hart's "Observations on County and Municipal Practice" touched on various matters involved in the development of an adequate national library system whether for science and technology or in any other field Earl Attlee's presidential address, succinct, wise and witty, illustrated the extent to which wide reading and the right handling of books are still positive constructive factors in modern life , and Lady Barlow discussed "Charles Darwin as Author"

Prof Hogben addressed himself to three issues Can other means of communication adequately replace the printed page ? Will their rightful exploitation diminish the demand for the printed page relative to the size of the literate public ? And how far does a plan of peaceful co-existence for the two call for a new programme of book design ? On the first, Prof Hogben remarked that 'adequately' was the operative word, and the freedom to turn the pages backwards or forwards to interpret the author's meaning in the light of previous statements or of what occurred later was an incentive to concentrated attention and acted as a brake on superficial assent To regard reliance on mechanized instruction without reliance on the printed page as calamitous did not mean that the more extensive use of sound or television should be regarded with disfavour or that such extension would curtail the need for book learning On the contrary, Prof Hogben thought that we would have to exploit new means of instruction and that radio sound and television could solve the modern problem of shortage of talented teachers in a world of wider educational opportunities if—and only if—we could give it a curricula orientation entirely divorced from the prepossessions of the entertainment business The exploitation of the newest visual aids did not mean that there would be need for fewer books in the near future In some of the backward territories there would be vastly more readers if we could use the new means to speed up universal literacy, and where literacy was already well-nigh universal the new means could so expand the appetite for learning as to stimulate powerfully the output of new informative literature

As regards the third question, while there was no reason to anticipate that the exploitation of the new means at our disposal would diminish the demand for the printed page, and ample reasons existed for believing that it would increase that demand, we could certainly forecast that it would increasingly change the content of what printed matter is in demand and set a new standard of design for books which satisfy an abiding demand Here Prof Hogben referred to the possibilities opened up by gearing issued and printed material into editions which could subserve two educational objectives, sentences of one line in length permitting repetition of the same message line by line in several languages In the new era the first challenge to intellectual effort was how most expeditiously we could make available to all persons everywhere the printed page , the second was how to make everywhere accessible to all, both one and the same printed page and one and the same human voice The third great intellectual challenge was how to disperse over an ever-widening and deepening understanding less of the mechanical techniques at our disposal than of the peculiarly human innovations

Sir Sydney Roberts began by pointing out that the central question his Committee had been asked to consider was what changes, if any, should be made in the administrative arrangements of the public library service, and this included possible transferences of responsibility from one type of library authority to another Although there were obviously two clashing views of the functions of a public library, both were agreed that the public library service, by whatever type of authority it might be administered, was essentially a feature of local government. Nevertheless, the Committee was clear that provision of library facilities should cease to be a local option and should become a statutory duty with ultimate authority vested in the Minister of Education. Librarianship, however, was a highly specialized function, and in Sir Sydney's view a committee responsible for a public library should be an independent committee reporting direct to the library authority. Directing attention to the Committee's comment that size and efficiency did not necessarily march together, and its view that full opportunity—at least three years—should be given to any non-county borough or urban district to demonstrate its ability to fulfil the required conditions before any change was made in its library status, Sir Sydney said that the Committee had had before it the proposals for the new National Lending Library for Science and Technology, and its consideration of such matters had confirmed its misgivings about the imperfections of the reference sections in many libraries. Co-operation between libraries of an entirely different character and constitution, however, could best be achieved by individual negotiation, in the light of local conditions, between the libraries concerned. The main obstacle to higher efficiency in the working of the regional bureau, however, was finance, and the Committee was not prepared to advocate a standard pattern of administration over the whole country. Finally, after touching on the problems of book selection, financial and otherwise, Sir Sydney pointed out that the public libraries must take full account of the implications of the scientific revolution in which we live. They must stock both the technological text-books and reference books needed by their industrial and academic clients and they must make a judicious choice of those authors who attempt to explain the basic principles of scientific development to the non-scientific reader. They had also to recognize the sociological results of scientific discovery and development and meet adequately the recreational needs of leisure.

Alderman F. J. Stott, who began with a quotation from the report of President Eisenhower's Science Advisory Committee, "Education for the Age of Science", stressing that the aim of an educational system must always be the development of the individual so that he could live the fullest life with himself and the community, elaborated further Sir Sydney Roberts's closing remarks. If the scientific age challenged technologists to make a special effort to ensure that their education was not detrimental to their balanced development as individuals and challenged non-technical people to keep in touch with the new language and thoughts of science, it was essential for our national welfare that we should stay in communication with each other, and the channels of communication could only be secured by the universal enjoyment of liberal education. Education, however, was being required to devote more and more of its resources to vocational and technical training at the expense of wider values, and while at work more and more were called upon to do less and less thinking, in our ever-increasing leisure more and more were content to leave the planning of their leisure to the instruments of mass entertainment.

In this situation, in which the integrity and full flowering of the individual were threatened on all three counts, Alderman Stott thought that the public library had an important part to play. A survey of readers recently made in the Plymouth public libraries indicated that, whereas in Plymouth 33,000 scholars at primary, secondary and grammar schools spend 33.5 million hours in attendance, 66,000 readers of all ages devoted 36.5 million leisure hours to reading, of which 15 million were devoted to reading of a deliberately self-chosen, informative and educational character. On the provision of this service some £80,000 a year was spent, compared with about £2 million on formal education in primary and secondary schools, but Alderman Stott, of course, emphasized that on two-thirds to three-quarters of the population the public library services made no impact at all. He did not think it was simply a matter of increasing the provision for public library services but rather, as Lord Attlee had suggested, for encouraging children early in life to use and cherish books. There was also need for much more publicity and some attempt to meet the needs of individuals.

INDUSTRY AND HEALTH IN BRITAIN

THE annual report of the Chief Inspector of Factories for the year 1958 follows the new form adopted last year, which was very well received, and there is again a separate report on industrial health (Ministry of Labour and National Service. Pp. 95. (Cmnd. 810.) London: H.M. Stationery Office, 1959. 5*s*. 6*d*. net). While the number of reported accidents fell by 4 per cent, from 174,713 to 167,697, and was the lowest reported for any year since 1935, fatal accidents rose from 651 to 665. For factories alone the figure declined by 5 per cent to 143,099, of which 368 were fatal; but in building operations and works of engineering construction there were increases from 14,568 to 15,017 and from 1,924 to 2,329, respectively. The former included a considerable increase in fatalities due to falls, especially of materials, and this appears to be due to much demolition work being carried out by inexperienced personnel with little or no appreciation of the loading and stresses in various parts of the structure on which they are working. No figures are available for accident incidence rates of individual industries, although the report gives comparative frequency rates, based on voluntary returns from individual firms, and it is hoped to publish a table of incidence rates in next year's report. The distribution of accidents between the sexes and between young persons and adults was little changed, but the report points out that, in spite of the emphasis placed on training young persons entering industry, 9,838 young persons were involved in notifiable accidents and 8 of them were killed. In some industries it is still true that the probability of an accident is greater for a young person than for an adult

The Chief Inspector directs attention to the increase in accidents due to transport other than rail, where the 1958 figure was more than double that for 1948, and to the need for much more attention to problems of safety in the use of road transport within factories and other work-places greater care, for example, might be exercised in selecting drivers and operators of such transport Accidents associated with the use of power presses again increased in spite of great efforts to evolve better designs and methods of guarding, and greater attention to maintenance of these machines and their guards appears to be needed

The new arrangement of the report gives prominence to the aspects of special interest to the scientist There is a separate chapter on the problems encountered by the Inspectorate in relation to nuclear energy and ionizing radiations, which covers electrical instrumentation and the control of nuclear reactors, as well as the preparation and fabrication of special metals used in reactors, the preparation of enriched uranium, the handling and treatment of irradiated fuel rods and sealed and open sources of radiation A chapter on fire prevention stresses the need to report dangerous occurrences which are not associated with personal injury, and attention is directed to the possibilities of eliminating sources of ignition by less hazardous arrangements as well as to the hazards associated with waste and with the handling of inflammable liquids even on a relatively small scale The limitations of devices based on developments in modern telecommunications techniques are discussed and special attention is directed to the hazards associated with organic peroxides Here and for the handling of mercury the report details a number of specific precautions, and the advantage of placing any potentially explosive plant, such as that for handling hydrogen, outside any occupied room and where explosion is unlikely to injure anyone if it occurs, is indicated The scientific interest of the work of the Inspectorate is further illustrated by the list of interdepartmental committees on which inspectors have served, and the report records 407 inspectors of all grades in posts at the end of the year with vacancies for nine general, eleven chemical, eight engineering and two medical inspectors

THE BRITISH FORESTRY COMMISSION

THIRTY-NINTH ANNUAL REPORT

AS remarked in the opening sentence of this report*, by far the most important event of the year in British forestry was the statement on policy made in Parliament In view of the developments and progress since the post-war policy was adopted in 1946, planting is to continue at approximately the current annual rate of 60,000 acres for another five years, after which a significant reduction, about a fifth, is envisaged, when the older plantations will be coming into full production at an age of around fifty years There is no specific abandonment of the old national target of five million acres of productive woodland for Britain as a whole, though it is recognized that its strategic basis has altered considerably No specific target is set for the planting of private woodlands, currently running at 32,000 acres annually, but the policy of encouraging planting and more intensive management is continued, the acreage grants being raised and somewhat modified Action is also being taken to improve the marketing of produce from these private woodlands as it has long been recognized as unsatisfactory, with consequent discouragement to owners and potential investors The increased grants were offered on condition that owners organized an effective association for marketing and connected purposes, and they have in fact now done this on a regional basis ; at the same time, the warning is given that the grants are not to be viewed as a permanent subsidy, but only as an initial stimulus and help which should fairly soon become unnecessary Felling licences will be continued, not to restrict felling to a predetermined quota, but to ensure acceptable felling practices and replanting where necessary

Once again, difficulties in acquiring the necessary land for the annual planting programme constitute a major handicap, and the necessity of paying rather higher prices than in the past is accepted It is hoped that more land will become available particularly in Scotland and Wales, where the expansion of forestry will provide diversification of employment and important social benefits

Although one of the most direct benefits of increased timber production in Great Britain should obviously be a gradual reduction of imports which run at present at around £170 million per annum, we should now be entering a phase of quite considerable development of wood-based industries , this should more than compensate for some drop in consumption of unprocessed wood, such as has occurred with pit-props and railway timbers The opening of a large hardwood pulp mill on the Severn estuary is an important event and is being followed by similar developments in various parts of Great Britain The possibilities of small-scale pulping are under special consideration and seem quite promising

Expenditure on research now stands at more than £300,000 annually A short summary of progress in the several branches of the work is included in this report though a full account is published separately Research facilities have been greatly improved during the year by the provision of a large new building which was formally opened in July

Reviewing the situation as a whole, it is clear that the decision taken forty years ago to remedy the extremely unsatisfactory forestry position in Britain has been acted on with a measure of success that rarely attends such long-term ventures, and we are now rapidly approaching the time when the returns, both direct and indirect, will be coming in at a rapidly increasing rate already sales of produce are bringing in more than £3,000,000 in the year

ULTRASONIC BARIUM TITANATE ADHESION AND PASTE TRANSDUCERS

By DR A LUTSCH*

National Physical Research Laboratory, South African Council for Scientific and Industrial Research,
P O Box 395, Pretoria

PRELIMINARY observations on the behaviour of two new types of transducer will be described to emphasize the possible importance of these generators They offer possibilities particularly in overcoming the following problems which arise in applying transducers available at present

(1) For the generation of elastic waves in solids at very high frequencies, a quartz crystal of a thickness of 0 1 mm —having a fundamental resonance frequency of approximately 30 Mc /s —is, due to fragility, the smallest thickness that can be used in practice

(2) The coupling layer between the transducer crystal and the test object should be as thin as possible, preferably less than $\lambda/20$ This again sets a limit for high-frequency applications

Exciting a crystal in its harmonic modes is not always a reliable method and does not solve the coupling problem The importance of extending the frequency-range is summarized in ref 1

(3) In addition, in non-destructive testing, the degree of coupling between an ultrasonic transducer and object is unknown[2] A firm and stable contact is desirable, but is especially difficult to obtain at rough and curved surfaces

(4) The resonance frequency of a crystal transducer is not variable—a disadvantage in some applications

New desirable transducer types and manufacturing methods are mentioned in ref 3

A transducer produced on the surface, forming an integral part with the test block, would avoid the handling of extremely thin crystals and the necessity of providing a coupling layer This is obviously not possible with conventional barium titanate transducers[4], because during the production a temperature of 1,350° C is required which cannot be tolerated for most test objects

The Barium Titanate Adhesion Transducer

Barium titanate powder was mixed with a liquid ethoxyline and heated to remove moisture After allowing this mixture to cool to a few degrees above room temperature, a hardener was added and the mixture was cast on the surface of a metal block (Fig 1) A ring made from an electrical insulating material of the same thickness as the desired ultrasonic transducer was placed on the surface of the metal block forming a casting mould for the mixture. Immediately after casting, while the mixture was still in a 'plastic' stage, a flat metal disk was placed on top of the ring The disk and the metal block form the electrodes and two defining surfaces of the mould A high-voltage direct current source was connected through a resistor to polarize the transducer, while simultaneously the electrical output of a conventional ultrasonic reflectoscope[5] was applied via a condenser The reflectoscope transmitted short electrical pulses to the transducer cast When the cast became operative as a transducer its performance could be deduced by observing the pulses reflected from the far end of the test block The metal disk and the casting mould ring were coated with a thin layer of a silicone paste before assembly It was found that this was sufficient to isolate the elastic vibrations of the transducer from the top electrode By thorough cleaning of the metal surface of the test block an intimate elastic coupling to the case was obtained The unit was heated to approximately 135° C and allowed to cool to room temperature, while the high-voltage source and the reflectoscope were still connected During this operation the mixture became a solid layer in firm contact with the test block, hence the name adhesion transducer

The reflexion from the far end of the test object was observed and showed an increase in amplitude with decrease in temperature The behaviour was tested by applying the pulses at carrier frequencies 0 5, 1, 2 5 and 5 Mc /s , which were available from the reflectoscope, to the same adhesion transducer

The majority of the subsequent tests were carried out at 2 5 Mc /s with a pulse length of 1 μsec The temperature cycle was repeated several times and the same result as described above was obtained On heating a polarized adhesion transducer while the direct voltage source was disconnected, a decrease

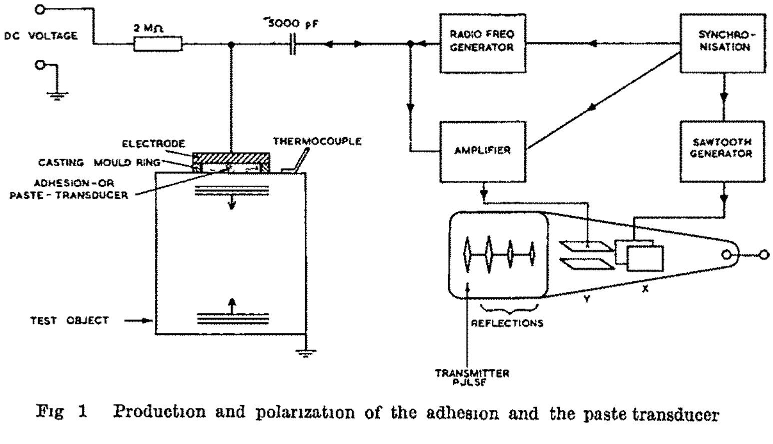

Fig 1 Production and polarization of the adhesion and the paste transducer

of the amplitude of the reflexion was observed If the temperature exceeded 135° C the amplitude dropped to zero and the transducer was depolarized On heating a polarized transducer without the d c field to a maximum temperature of, say, 120° C, which is below the Curie temperature of conventional barium titanate transducers, its piezo-electric properties recover after cooling down but the amplitude of the reflexion does not increase to the original value

---

* Present address Brown University, Providence, Rhode Island U S A

While the optimum composition of the mixture from which the adhesion transducer was made is still being investigated, an attempt has been made to determine the effect of different barium titanate powder sizes One problem for further investigation would be to test the expected usefulness of the adhesion transducer as a generator for high-frequency elastic waves Since it can be expected that the relation of wave-length to grain size will be important in determining high-frequency limitations, the following tests were carried out Because no electronic apparatus with higher carrier frequencies than those already mentioned was available, coarser powder was used while the frequency was held constant in an effort to obtain an estimate of the effectiveness of fine powder at correspondingly higher frequencies Powder diameters between $d = 50$ μm and 500 μm in five grades were available The velocity of sound of the transducer for compressional waves was found to be $2\ 7 \times 10^5$ cm /sec The following measurements were also made at a carrier frequency of 2 5 Mc /s The corresponding ratios of the wave-length in the transducer to the powder diameter d were $21 > \lambda/d > 2\ 1$ No significant differences in the observed reflexion amplitudes were observed, the coarse grain transducer ($\lambda/d = 2\ 1$) seeming if anything to be slightly more effective

The electrical impedance of the adhesion transducer was found to be considerably higher and the dielectric constant considerably smaller (ε_r approximately 7) than the corresponding values for conventionally made barium titanate transducers

The adhesion transducer as described was hardened for a few minutes at a temperature above 100° C The polarization of the transducer made from fine powder was effective only if the temperature exceeded 135° C On the other hand, the use of coarse powder in making adhesion transducers allows an important modification of the manufacturing procedure The remarkable effect was observed that they could be polarized by application of a d c field at room temperature, while the transducers were still in the 'plastic' stage forming a thick paste The hardening can take place at room temperature, but hours or days are required, the actual time depending on the mixing ratios, the physical dimensions, and ambient temperature This modification is important where test objects cannot tolerate a temperature of 135° C After the transducer has hardened to a solid layer, it can be de- or re-polarized only above 135° C in the manner already described

The Barium Titanate Paste Transducer

The procedure for manufacturing a paste transducer is identical with that described at the end of the last paragraph, except that no hardener is added to the mixture and only grain sizes above a certain value are useful The mixture remains a paste independent of temperature and time It is polarized at room temperature The first polarization curve and the hysteresis loop of the de- and re-polarized curve are shown in Fig 2

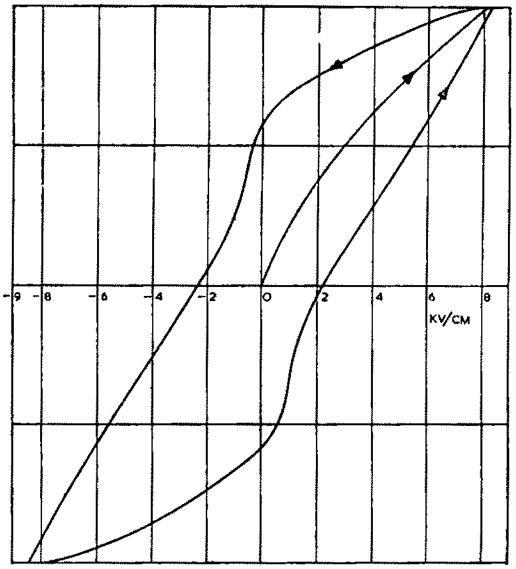

Fig 2 Ferro-electric hysteresis of a paste transducer Amplitude in percentage of the reflexion from the far end of the attached test block as a function of the polarization field in kV /cm Measured at 2 5 Mc /s , and 25° C

The paste transducer can be de-polarized (i) by means of stirring the paste , (ii) by means of a d c field of an appropriate negative value (see Fig 2) The behaviour of these paste transducers was totally unexpected in that unlike conventionally made barium titanate transducers and the adhesion transducer it was found still to operate above 135° C Even at 200° C a reflexion amplitude of 66 per cent and at 300° C of 40 per cent of the value measured at room temperature was observed The piezo-electric performance of the paste transducer is also less dependent on temperature than that of the adhesion transducer

A paste transducer made from finer powder was found to be less effective, and for the finest available size no piezo-electric effect was measured An obvious advantage of the transducer in paste form would be that by altering the distance between the upper disk electrode and the test block, using a casting mould ring of an elastic material, the transducer could be tuned to $\lambda/2$ for a given frequency of the electrical oscillator

Stability of Performance of the Transducers immediately after Polarization

After removing the polarization d c voltage on a paste transducer it was found that the amplitude of the reflected pulse decreased from 100 to 63 per cent in approximately 10 sec , and to 60 per cent (as shown in Fig 2) during the subsequent minute, after which it remained practically constant No further ageing could be observed over a period of two weeks

By adding a hardener, as described for the production of the solid adhesion transducer, a hardening time of several days can be arranged using a suitable low temperature The following remarks concern a transducer with a final hardening time of two days Immediately after the hardener was added the same behaviour as mentioned above for the paste transducer was observed Removal of the polarization field 2 hr after the addition of hardener increased the 100 to 63 per cent reflexion decay-time mentioned previously, from 10 sec to several minutes. In later stages between the 'plastic' and solid state this time may further increase to several hours. No decay was observed after the transducer layer had become a solid.

Some Aspects of the Application of the New Transducers for the Non-destructive Testing Technique

A useful application of the transducers is in the non-destructive testing of objects having a rough or curved surface. Unlike conventional transducer probes they are in direct contact with the object. Furthermore, no damping block on the back of the crystal is required for increasing the frequency band-width, as is necessary in conventional transducers, because the mechanical damping of most test objects is sufficient even at a rough surface. Detuning of the transducer, having a band-width, caused by a rough or irregular surface, is not of importance in practice; this can be corrected by re-tuning in the case of the paste transducer, as already mentioned above. At rough surfaces a reflectoscope, operating with the new transducers, should be capable of detecting cracks with a smaller area or at a greater distance from the transducer than is possible with a conventional apparatus. The so-called 'dead zone' would also be smaller because the transducer band-width is wider and therefore shorter pulses can be applied.

Theoretical investigation and further experimental work are continuing to (*a*) explain the observed ferro-electric and dielectric behaviour; (*b*) extend the frequency-range of the transducers by considering, for example, possible spray and evaporation techniques for obtaining physically thin layers.

I thank Mr J D N van Wyk of the National Physical Research Laboratory for valuable discussions, and Mr E R Schmidt for preparing the barium titanate powder.

INCORPORATION OF N-METHYL CARBON OF MONOMETHYLAMINOAZOBENZENE INTO POLAR DYES

By Prof. HIROSHI TERAYAMA

Department of Biophysics and Biochemistry, Faculty of Science, University of Tokyo

AND

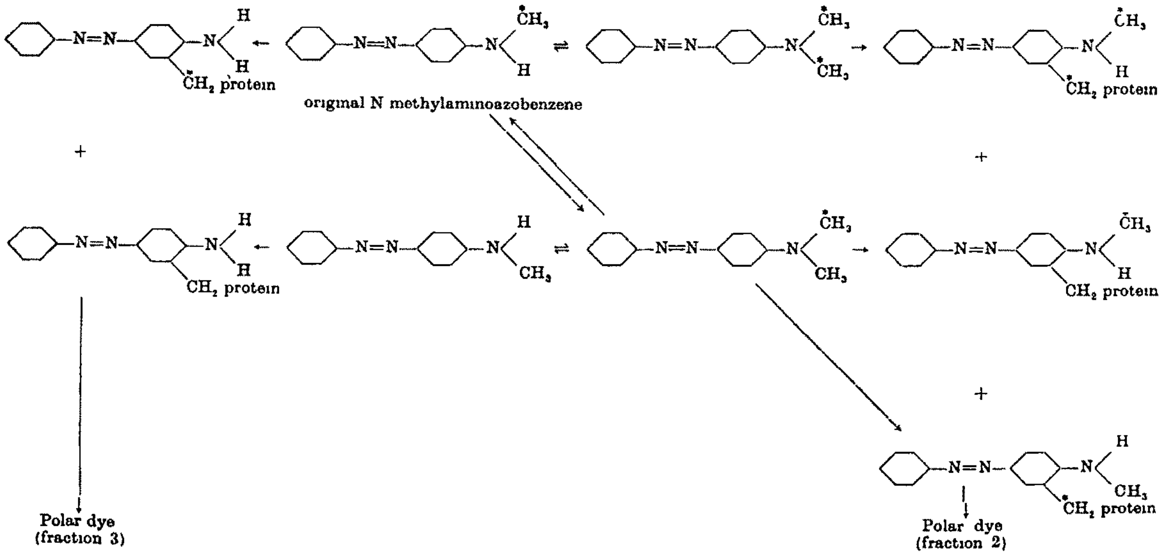
Prof MORIZO ISHIDATE and AKIRA HANAKI

Faculty of Pharmaceutical Science, University of Tokyo

THE chemical binding between carcinogenic aminoazo dyes such as dimethylaminoazobenzene and cellular protein of rat's liver was first discovered by the Millers[1], who then proposed the protein deletion hypothesis as the basis of chemical carcinogenesis.

The chemical nature of the binding, however, has not been sufficiently investigated, due to the difficulty of purifying the polar dyes from the hydrolysate of the dye-bound liver proteins as well as the small amounts available. Terayama *et al* recently studied the purification of the natural polar dyes from the hydrolysates of the dye-bound rat liver proteins[2,3] and discovered the presence of at least two types of polar dyes, depending on the nature of the amino group of the dye moiety, one having the primary (fraction 3) and the other having the secondary amino group (fraction 2)[3,4]. They also showed that the binding is at position 3, ortho to the amino group, in the dye moiety of polar dyes prepared from rat liver after the administration of dimethylaminoazobenzene or N-methylaminoazobenzene[3]. Evidence for position 3 binding is the remarkable spectral change (disappearance of the 500–520 mμ absorption in acid media) shown by the polar dyes after the 4 position amino group of the polar dyes is methylated up to the dimethylamino group with a mixture of formaldehyde and formic acid. The binding at position 4-amino group[5] was excluded so far as the acid-stable polar dyes (fractions 3 and 2) derived from dimethylaminoazobenzene or N-methylaminoazobenzene are concerned. This was confirmed by the result of the comparison with the synthetic acid-labile polar dyes which have the amino-acid substitution at the amino group (Mannich base)[3,6]. The amino-acid which is responsible to the binding in the protein moiety was assumed to be tyrosine mainly from the strong Folin–Ciocalteau's reaction, ultra-violet absorption and stability against acid treatment of the polar dyes[3]. The bridge to bind the dye to the tyrosine residue was thought tentatively to be a methylene[3] or oxymethylene, —OCH$_2$— (unpublished work), group mainly on account of the necessity for at least one N-methyl group in the potent carcinogenic aminoazobenzene dyes as indicated by the Millers[6,7]. Direct evidence in support of the presence of a methylene (or oxymethylene) bridge has, however, been lacking. The present communication gives experimental support for the incorporation of the N-methyl group of N-methylaminoazobenzene into the polar dyes at a position other than the 4-amino group of the dye moiety.

N-^{14}C-methylaminoazobenzene was administered to rats and the polar dyes were prepared, fractionated and measured by the radioactivity as well as the optical absorption. 25 mgm of the labelled compound in 2 ml of olive oil was administered intragastrically under ether anæsthesia. The rats thus treated were killed 3 days later, livers removed and the polar dyes prepared as described in earlier papers. The partially purified mixture of polar dyes in 2 *N* hydrochloric acid was submitted to '*IRC*-50' (*H* type) column chromatography. The dyes were adsorbed at the top of the column, washed with



Scheme for the formation of protein-dye *in vivo* upon the administration of labelled N-methylaminoazobenzene

2 *N* hydrochloric acid, water and 30 per cent alcohol successively and then eluted with 60 per cent alcohol Three fractions were separated The portion not removed with 60 per cent alcohol was then eluted with 2 *N* ammonia (fraction 4) Fraction 1 seems to be contaminated with a small amount of non-polar dye Fraction 2, a major component, having absorption maximum at 522 mμ in 2 *N* hydrochloric acid in 50 per cent alcohol, is the polar dye with the secondary amino group, and fraction 3, a minor component, having absorption maximum at 514 mμ in the same solution, is the polar dye with the primary amino group Fraction 4 seems to be a mixture of the polar dyes with the longer polypeptide chains and can be further fractionated after being hydrolysed again The acid-stable fractions 2 and 3 were rechromatographed The radioactivity and the optical density measurements for the portions of the eluates are closely paralleled

The specific radioactivities of the purified polar dyes (fractions 2 and 3) are listed in Table 1 Since we do not know the exact molar extinction coefficients of the polar dyes, the amount of the fraction 2 polar dye is expressed in terms of N-methylaminoazobenzene or 3-methyl-N-methylaminoazobenzene, and for the fraction 3 polar dye in terms of aminoazobenzene or 3-methylaminoazobenzene tentatively It is very interesting to see that the polar dye having the primary amino group, fraction 3, still holds an appreciable amount of the radioactivity derived from the N-methyl group of the original N-methylaminoazobenzene This demonstrates clearly that the N-methyl group of the latter is certainly incorporated into the polar dye at a position different from the position 4-amino group The specific activity of fraction 2 polar dye seems to be greater than that of fraction 3, the original radioactive N-methylaminoazobenzene being intermediate Although the comparison of radioactivity in a strictly quantitative sense should be suspended until the exact molar extinctions of the polar dyes are elucidated, the result obtained here might be explained by assuming that the N-methylaminoazobenzene administered is further methylated *in vivo*, as indicated by the Millers[8,9], via the methyl pool, which is partly endogenous and partly derived from N-methyl metabolism of the radioactive N-methylaminoazobenzene, thus forming doubly labelled dimethylaminoazobenzene, which is then metabolized in the liver It seems reasonable to assume that fraction 2 polar dye is derived from the latter thus formed *in vivo* and the fraction 3 polar dye from N-methylaminoazobenzene, the radioactivity of which might be somewhat diminished *in vivo* as the result of the intracellular demethylation and methylation reactions, as shown in the accompanying scheme

Table 1 (*a*) YIELD OF POLAR DYES

From five rats, 25 mgm N-methylaminoazobenzene in 2 ml olive oil per rat

Polar dyes	Yield (γ) (in terms of N-methylaminoazobenzene)
Total polar dye, unfractionated	72 5
Fraction 1*	15 3
Fraction 2	30 7
Fraction 3	16 9
Fraction 4	5 4

* A part of fraction 2 is mixed in this fraction

Table 1 (*b*) SPECIFIC RADIOACTIVITY OF THE PURIFIED POLAR DYES

Polar dyes	Specific radioactivity (c p m /γ)
Fraction 2	580 ± 27 (in terms of N-methylaminoazobenzene) *c* 580 (in terms of 3-methyl-N-methylaminoazobenzene)
Fraction 3	224 ± 18 (in terms of aminoazobenzene) *c* 270 (in terms of 3-methyl-N-methylaminoazobenzene)
N-^{14}C-methylaminoazobenzene (administered)	430 ± 22

OXYGEN-CONTAINING FUNCTIONAL GROUPS IN THE ORGANIC MATTER OF A PODZOL SOIL

By J. R. WRIGHT and M. SCHNITZER
Soil Research Institute, Research Branch, Canada Agriculture, Ottawa

IT has long been recognized that there is a close connexion between the mobilization and immobilization of metals and that of organic matter in the development of podzol soils. The mechanism involved remains obscure, largely because little is known about the chemical constitution of the organic material(s) moving from the *Ao* through the *Ae* into the *B* horizon of the profile. It seems reasonable to assume that the organo-metallic reactions involved depend on the nature and numbers of functional groups. For this reason, a systematic study was undertaken of such groups in the organic matter of the *Ao* and *Bh* horizons of the Armadale soil, a poorly drained podzol from Prince Edward Island[1]. This report deals only with oxygen-containing functional groups.

The organic matter from both horizons was extracted with 0·5 *N* sodium hydroxide solution. Parallel extractions were made under air and under nitrogen in order to evaluate possible effects of air-oxidation[2]. Following extraction, the organic matter of the *Ao* horizon was dialysed exhaustively against distilled water, while that of the *Bh* horizon was passed over 'Amberlite *IR*-120' exchange resin in order to remove most of the inorganic cations. Both extracts were then concentrated to near dryness on the steam-bath and finally dried at 100° C. under nitrogen. Where extractions were made under nitrogen, the most stringent precautions were taken to exclude air during extraction and purification. Wherever possible, the analytical data were checked by independent methods. Total acidity was measured by baryta absorption under nitrogen[3] and carboxyl groups by reaction with calcium acetate and with iodate–iodide[4]. Total hydroxyls were determined by acetylation[4,5] and phenolic hydroxyls by reaction with barium hydroxide[6] and by a modified Ubaldini procedure[7]. All hydroxyl determinations were made under nitrogen. Carbonyl groups were measured by the method of Brooks *et al.*[8] and methoxyls by Zeisel's method[9]. Ultimate analyses were done by dry-combustion. Infra-red spectra were recorded on a Perkin–Elmer Model 21 spectrophotometer, using potassium bromide pellets[10].

Irrespective of whether extractions were carried out under nitrogen or air, the material from the *Ao* was higher in carbon, hydrogen and nitrogen but lower in sulphur and oxygen than that from the *Bh* horizon (Table 1). A comparison of the results for functional groups in the *Ao* and *Bh* materials extracted under nitrogen showed that: (*a*) the *Bh* material was considerably more acidic, due entirely to the presence of more carboxyl groups; (*b*) the *Bh* organic matter was higher in total and consequently alcoholic hydroxyls since the phenolic hydroxyl content of both materials was similar; (*c*) there was little difference in the carbonyl content, and (*d*) the *Ao* organic matter contained more methoxyl groups (possibly because of the presence of undecomposed lignin).

Table 1. ANALYTICAL CHARACTERISTICS

Elementary composition (per cent) (dry ash-free basis)	*Ao* material extracted Under N	*Ao* material extracted Under air	*Bh* material extracted Under N	*Bh* material extracted Under air
Carbon	56·92	57·16	50·22	49·50
Hydrogen	5·20	5·30	3·74	3·62
Nitrogen	2·34	1·87	0·72	0·67
Sulphur	0·70	0·68	1·30	1·33
Oxygen (by difference)	34·84	34·99	44·02	44·88
Ash (dry basis)	8·87	8·25	3·02	3·85
Functional groups (m.-equiv. per gm. dry ash-free organic matter)				
Total acidity	4·7	4·7	11·4	11·5
Carboxyl	1·5	1·9	8·2	8·6
Total hydroxyl	3·2	6·0	5·0	5·1
Phenolic hydroxyl	3·2	2·8	3·2	2·9
Alcoholic hydroxyl (total minus phenolic)	0	3·2	1·8	2·2
Carbonyl	6·0	3·6	6·2	5·5
Methoxyl	0·4	0·4	0·2	0·2

The results for total and alcoholic hydroxyls (difference between total and phenolic) may be high, since total hydroxyls were determined by acetylation with acetic anhydride. This reagent[11], besides reacting with hydroxyls of primary and secondary alcohols and of phenols, also reacts with sulphydryl groups and primary and secondary amines. What proportion of the total nitrogen and sulphur is present as such groups is not known.

The most important changes in the distribution of functional groups when the organic matter was extracted under air (in contrast with nitrogen) were the following: (*a*) a decrease in carbonyl and an increase in alcoholic hydroxyl groups suggesting, in part, some form of keto-enol transformation; (*b*) a small increase in carboxyls and a concomitant equivalent decrease in phenolic hydroxyls. Durie and Sternhell[12] found a similar 1 : 1 correspondence between the decrease in phenolic hydroxyls and the increase in carboxyls on oxidizing brown coal in alkaline solution in the presence of oxygen. They concluded that the increase in carboxyl groups arose from phenolic groups.

There were no changes in the total acidity and methoxyl content of the organic matter whether extracted under air or under nitrogen.

Table 2 shows that whereas all the oxygen of the *Bh* organic matter was found in the functional groups, only 60 per cent of the oxygen of the *Ao* material

Table 2. DISTRIBUTION OF OXYGEN IN FUNCTIONAL GROUPS

	$\frac{\text{O as COOH}}{\text{Total O}}$	$\frac{\text{O as OH}}{\text{Total O}}$	$\frac{\text{O as CO}}{\text{Total O}}$	$\frac{\text{O as CH}_3\text{O}}{\text{Total O}}$	$\frac{\text{O accounted for}}{\text{Total O}}$
Ao material extracted under nitrogen	0·14	0·15	0·28	0·02	0·59
Ao ,, ,, ,, air	0·15	0·27	0·16	0·02	0·60
Bh ,, ,, ,, nitrogen	0·60	0·18	0·23	0·01	1·02
Bh ,, ,, ,, air	0·61	0·18	0·20	0·01	1·00

Table 3 MAJOR BANDS AND RELATIVE ABSORBANCES IN THE INFRA-RED OF EXTRACTED ORGANIC MATTER

Frequency (cm $^{-1}$)	Relative absorbance *Ao* organic matter	 *Bh* organic matter	Interpretation*
3,380	strong	strong	hydrogen bonded —OH and bonded —NH groups
2,910	medium	shoulder	aliphatic C—H stretching vibrations

1,620	strong	strong	joint interaction of hydroxyl and carboxyl with carbonyl (ref 13), also possibly carboxylic groups associated with metals so as to give the carboxylate structure (ref 11)
1,450	strong	0	CH_3 and/or CH_2 in plane deformation vibrations
1,400	0	medium	carboxylate
1,250	weak	0	phenoxy C—O
1,200	0	medium	carboxyl
1,030	medium	0	Si—O of silica due to the presence of clay

* After Bellamy (ref 14) unless stated otherwise

was similarly distributed The remaining 40 per cent was probably present as ring and/or ether oxygen Unfortunately, all systematic errors which occurred in the determination of the other oxygen groups are accumulated in this figure (O accounted for)

The information from infra-red absorption spectra (Table 3) confirmed the chemical evidence with regard to the presence of the major oxygen-containing functional groups In addition, the infra-red spectra suggested that the *Ao* material was more aliphatic in nature than the *Bh* material There were no detectable differences in the infra-red spectra whether the organic matter was extracted under nitrogen or air

The major functional groups (carboxyls, hydroxyls and carbonyls) found in the organic matter of both horizons are known to react with metals such as iron and aluminium Therefore, the presence of large numbers of such groups, especially in the organic matter of the *Bh* horizon, offers a partial explanation for the observed reactivity to metals of this type of organic matter during the formation of podzol soils

ACTIVE PRINCIPLES OF THE NEUROHYPOPHYSIS OF COLD-BLOODED VERTEBRATES

Chromatographic and Biological Characteristics of Fish and Frog Neurohypophysial Extracts

THE neurohypophyses of all mammals so far investigated contain oxytocin and arginine vasopressin, with the exception of that of the pig, which contains oxytocin and lysine vasopressin There are some indications, however, that the active principles in the glands of other vertebrate classes may differ from the mammalian peptides For example, it has been shown[1] that, in frogs kept in water, the increase in weight produced by the injection of the extract of a single frog pituitary is matched by about 1,000 mU mammalian oxytocin but that, assayed on a mammalian uterus, a frog gland contains only about 40 mU oxytocic activity A similar difference in the ratio of activities has been shown by Sawyer[2] in the bullfrog

In view of these indications, it was decided to investigate further the active principles in non-mammalian neurohypophysial extracts The pituitary glands of three species of fish (trout, cod and pollock) and of frogs (*R temporaria*) were used Extracts of these glands produced oxytocic, vasopressor, antidiuretic, milk ejection and frog water-balance effects The oxytocic and vasopressor activities were completely abolished by treatment with sodium thioglycollate The resistance of the other activities to such treatment has, as yet, not been investigated

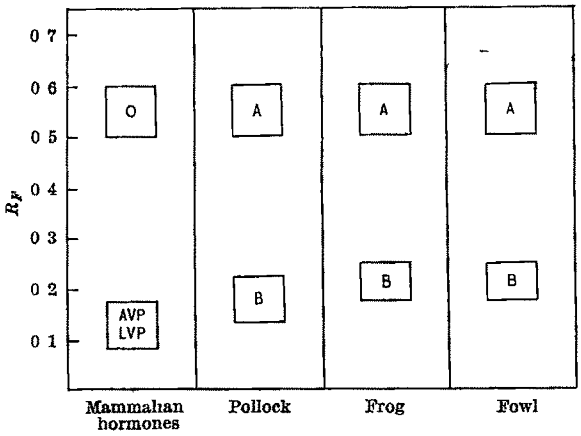

Fig 1 Descending paper chromatograms of acetic acid extracts of mammalian and non-mammalian pituitary glands The squares represent areas from which active substances could be eluted Oxytocin (*O*), arginine vasopressin (*AVP*), lysine vasopressin (*LVP*), fast-moving oxytocic activity (*A*) and slow-moving oxytocic activity (*B*)

When subjected to descending paper chromatography in butanol/acetic acid/water (4 1 . 5) and stained by the method of Heller and Lederis[3], eluates containing oxytocic activity were obtained from two regions of the paper (Fig 1) Eluate *A*, which was obtained from the same region as mammalian oxytocin, contained only a trace of antidiuretic activity and no pressor activity could be detected Thus, almost all the pressor and antidiuretic activity of the original extract was found in eluate *B* Both eluates caused milk ejection in the lactating rabbit and an increased uptake of water in frogs As Fig 2 shows, however, the frog water-balance effect of eluate *B* was much greater than that of eluate *A*

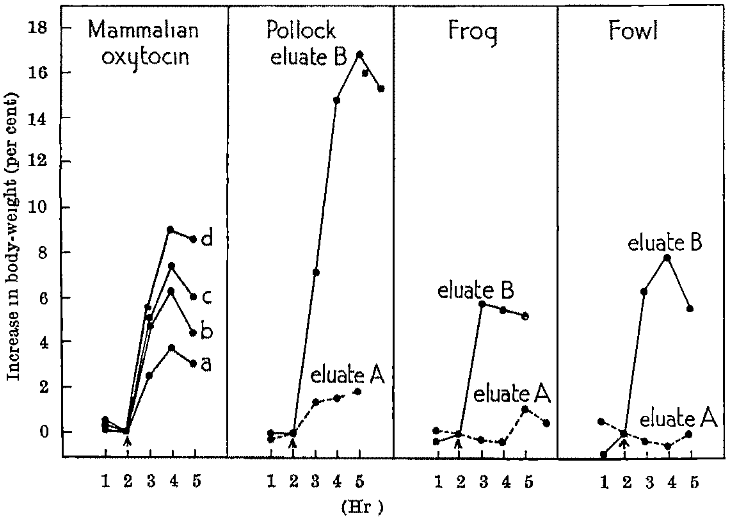

Fig 2 Effects of eluates *A* and *B* (see Fig 1) on frog water-balance The volumes of eluates injected per frog had the following activity as assayed against synthetic oxytocin on the isolated rat uterus Pollock, eluate *A*, 76 mU , eluate *B*, 101 mU Frog, both eluates, 7 5 mU Fowl, both eluates, 12 3 mU (*a*) 100 , (*b*) 300 , (*c*) 600 , (*d*) 900 mU oxytocin Injections at arrow The results shown are the mean responses of five or six frogs

It would seem, therefore, that the pituitaries of the three teleosts (two sea-water and one fresh-water species) and the amphibian investigated contain at least two oxytocic hormones, one of which behaves chromatographically and pharmacologically much like mammalian oxytocin The other, which differs from the vasopressins in its marked oxytocic and frog water-balance activity, also seems to occur in fowl posterior pituitaries (Fig 1) These results raise the interesting possibility that the hypothalamus of the vertebrate classes mentioned elaborates oxytocin and another active peptide not present in mammalian glands

We should like to thank Dr Grace Pickford for kindly supplying the pollock pituitary powder used in these experiments

Pharmacological Evidence for the Presence of Arginine Vasotocin and Oxytocin in Neurohypophysial Extracts from Cold-blooded Vertebrates

Munsick, Sawyer and van Dyke[1] have reported that chicken neurohypophysial extracts contain two active polypeptides One appears to be oxytocin A second peptide, present in greater quantity, has pharmacological and chromatographic characteristics indistinguishable from those of arginine vasotocin

Arginine vasotocin was synthesized by Katsoyannis and du Vigneaud[2] and kindly supplied by them for pharmacological study in this Department It is unique among the neurohypophysial hormones and analogues that we have studied in that it has activities on the isolated hen or turtle oviduct, on frog water-balance and diuresis, and on water transport across the bladder-wall of the frog far greater than one would predict from its vasopressor and oxytocic potencies

Heller[3,4] demonstrated that neurohypophysial extracts from fish, frog, snake and pigeon have frog water-balance activity much greater than that of mammalian extracts This observation suggests that they contain a peptide active on frog water-balance that is neither oxytocin nor vasopressin Since arginine vasotocin is such a peptide and has been tentatively identified in the avian neurohypophysis, we have studied neurohypophysial extracts from cold-blooded vertebrates to determine if their pharmacological characteristics are consistent with those of arginine vasotocin

Extracts from the green turtle (*Chelonia mydas*), the bullfrog (*Rana catesbiana*), the common American toad (*Bufo americanus*), the pollack (*Pollachius virens*), and the marine lamprey (*Petromyzon marinus*) were assayed by rat vasopressor, rat antidiuretic, rat uterus with and without magnesium, rabbit milk-ejection, hen oviduct, and isolated bullfrog bladder assays[1,5,6] The ratios of potencies by pressor, antidiuretic, hen uterus and frog bladder assays were, in each case, completely consistent with the relative activities of arginine vasotocin on these assays In all but *Petromyzon* there was more rat uterus and milk-ejection activity than could be due to arginine vasotocin alone This is consistent with the assumption that oxytocin is also present in all but the lamprey

One extract of the neurohypophysis of *Squalus acanthias* (spiny dogfish) has also been subjected to this series of assays Its pharmacological profile is not that of arginine vasotocin, oxytocin, or of any analogue that we have yet studied

We can advance the hypothesis, therefore, that arginine vasotocin and oxytocin occur in birds, reptiles, amphibians and teleosts Arginine vasotocin also appears in the most primitive living vertebrates, the cyclostomes The one elasmobranch studied appears to possess an active peptide unlike any that we have encountered elsewhere among the vertebrates

This investigation was supported by grants *A*1940 and *H*1788 from the National Institutes of Health, U S Public Health Service, and from the N Y Heart Association and the Smith, Kline and French Foundation

Arginine Vasotocin

IN connexion with the programme being carried out in this Department on the relationship of the structures of the posterior pituitary hormones to their biological properties, an analogue was synthesized[1] containing the ring of oxytocin attached to the side-chain of arginine vasopressin , for convenience, this substance was called arginine vasotocin This highly purified compound was tested for its uterus-contracting activity with the isolated rat uterus and for its pressor activity in the rat Our best information at the present time is that the arginine vasotocin has approximately twice the rat-uterus contracting activity and about one-fourth the rat-pressor activity of arginine vasopressin

Although the arginine vasotocin is not as active with regard to pressor activity as arginine vasopressin, the high pressor activity of the vasotocin is noteworthy in indicating the contribution to pressor activity of the basic amino-acid in the side-chain, since oxytocin, which differs from arginine vasotocin in having leucine in place of arginine in the side-chain, has approximately one-tenth the pressor activity of the arginine vasotocin The results also indicate that the phenylalanine in the ring of arginine vasopressin is of significance to pressor activity, since the vasopressin is more active than vasotocin, which has *iso*leucine in place of the phenylalanine Furthermore, the fact that arginine vasotocin has twice the oxytocic activity of arginine vasopressin indicates that *iso*leucine in place of phenylalanine raises the oxytocic activity In other words, replacement of phenylalanine by *iso*leucine has decreased the pressor activity and raised the oxytocic activity

Because of the interesting pharmacological properties of arginine vasotocin, a sample of the synthetic product was made available to Prof H B van Dyke for more extensive pharmacological investigation

In view of the strong evidence of the possible occurrence of arginine vasotocin in non-mammalian sources adduced by Sawyer, Munsick and van Dyke (preceding communication) and the possible correlation of their work with the results of Pickering and Heller (preceding communication) on the occurrence of an active peptide in certain non-mammalian vertebrate neurohypophyses, it was felt that this brief communication on arginine vasotocin would be appropriate

If subsequent chemical results substantiate the evidence for the occurrence in Nature of arginine vasotocin, the synthesis of the arginine vasotocin would represent a remarkable example of the synthesis of a polypeptide hormone before its identification as a natural product

COUNTER-CURRENT DISTRIBUTION OF PROTEINS IN AQUEOUS POLYMER PHASE SYSTEMS

By PER-AKE ÅLBERTSSON and ED JACQUES NYNS*

Institute of Biochemistry, University of Uppsala, Sweden

THE method of counter-current distribution has been shown to be one of the most efficient tools for analysing mixtures of substances of biochemical interest such as polypeptides So far, it has mainly been applied to low molecular substances but recently a number of proteins such as insulin[1], adrenocorticotropine[2], growth hormone[2], lactogenic hormone[2], lysozyme[3,4], ribonuclease[4], casein[5-7], serum albumin[8], and hæmoglobin[9] have also been successfully distributed One of the advantageous features of counter-current distribution is that it is based upon several steps each involving a state of equilibrium between two liquid phases Generally a state of equilibrium is supposed to be more easily obtained between two liquid phases than between, for example, a solid phase and a liquid phase For macromolecules this difference in equilibrium behaviour may be expected to be more pronounced than for low molecular weight substances It would therefore be of the greatest interest if counter-current distribution can be applied also for large molecular weight substances such as proteins and nucleic acids Many difficulties present themselves, however, when carrying out liquid–liquid extractions of proteins Thus they show a general tendency, due to their large molecular size, to be distributed unilaterally and there is always a risk of denaturation which may be caused by the interfaces and the organic solvents of the phase system In some cases, for example, with serum albumin[8], these difficulties have been successfully avoided by introducing complexing agents such as trichloracetic acid The effect of these is to stabilize the protein against denaturation and to make it more soluble in the organic phase

The present communication describes another approach to overcome these difficulties, namely, the

---

* Present address Laboratory of Biochemistry II, University of Louvain, Belgium

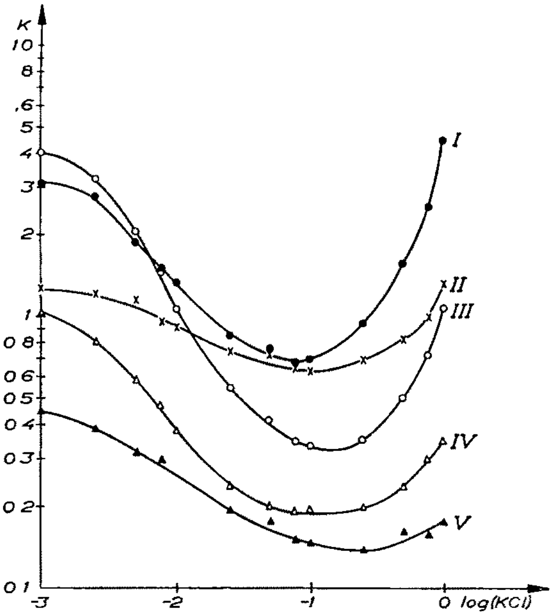

Fig 1 The partition coefficient (K) as a function of potassium chloride concentration for a number of proteins in a two-phase system of dextran and polyethylene glycol The curves represent phycocyanin (I), barley albumin (II), phycoerythrin (III), cæruloplasmin (IV), and human serum albumin (V) The system contains 0 005 mole potassium dihydrogen phosphate, 0 005 mole potassium monohydrogen phosphate, and potassium chloride as indicated, all per 976 ml of the phase system (976 ml is the volume of 1 kgm standard phase system which has a composition of 7 per cent (w/w) dextran, 4 4 per cent (w/w) polyethylene glycol, and 88 6 per cent (w/w) water) The protein in the two phases was estimated by determining the extinction at 545 mμ for phycoerythrin, the extinction at 620 mμ for phycocyanin, the nitrogen according to the Kjeldahl method for serum albumin, the enzyme activity for cæruloplasmin, and with the biuret method for barley albumin

use of aqueous polymer phase systems[10,11] based upon the fact that different polymer solutions in general are not miscible[12,13] These systems are obtained by mixing water solutions of two different polymers, for example, dextran and methylcellulose or dextran and polyethylene glycol Of the two phases in such a system the one phase usually contains most of one polymer and the other phase most of the other polymer The important point is that the water content is high in both phases and that the interfacial tension is very small Most proteins will, therefore, dissolve easily without denaturation This has been demonstrated for a number of proteins[11] and viruses[14] in a dextran–methylcellulose system The same system has also been used for the enrichment and purification of viruses[15,16] and for the fractionation of brain microsomes[17]

For the present study we have used a system of dextran and polyethylene glycol mainly because its phases have comparatively low viscosities, particularly the top phase (the polyethylene glycol-rich phase), which is the moving one In addition, reasonable times for phase separation (15–30 min) may be obtained by this system The following fractions of the polymers were found to give suitable conditions dextran with a viscosity number of 0 48 dl /gm ('Dextran 500' from Pharmacia, Uppsala, Sweden, and 'Carbowax polyethylene glycol 6000' from Carbide and Carbon Chemicals Co , U S A) A phase diagram of the system, and the way in which the polymers may be purified before use, will be described elsewhere[18,19] The phase system which has been used throughout contained 7 per cent (w/w) dextran and 4 4 per cent (w/w) polyethylene glycol, the rest being water or buffer The compositions of the upper and lower phases of this system at + 20° C are 0 2 per cent (w/w) dextran, 7 7 per cent (w/w) polyethylene glycol, 92 1 per cent (w/w) water and 14 4 per cent (w/w) dextran, 0 9 per cent (w/w) polyethylene glycol, 84 7 per cent (w/w) water, respectively The viscosities of the top phase and the bottom phase are about 4 and 60 centipoises, respectively

A striking characteristic of this system is the great dependence on the salt composition of the partition coefficient (K) for many proteins Thus, for example, phycoerythrin is mainly in the top phase ($K = 5$) in the presence of 0 01 M phosphate buffer (*p*H 6 8) If increasing amounts of potassium chloride are added the protein is pushed down into the bottom phase until a minimum value of $K = 0$ 33 is obtained Further addition of potassium chloride then causes the protein to be transferred to the top phase again Fig 1 serves to illustrate this salt effect for a number of proteins and it may be seen there that it is rather different for different proteins This salt effect has been studied systematically and will be described elsewhere[18,19]

The counter-current distributions were run on the two proteins phycoerythrin ($M = 290{,}000$) and phycocyanin ($M = 150{,}000$), which had been isolated from the red alga *Ceramium rubrum*[20] and purified by twice repeated chromatography on calcium phosphate[21] An automatic apparatus, constructed similarly to the Craig glass apparatus[5], was used The volumes of the phases were about 10 ml each, the settling time 35 min , and the number of shakings 50 The results from three experiments are given in Figs 2, 3 and 4 The aim of the two first experiments (Figs 2 and 3) was to see if the distribution of the protein followed the theoretical distribution law A K-value of about 1 was desirable for these experiments and the salt composition necessary to give this was selected with the aid of the curves of Fig 1 As may be seen in Figs 2 and 3, the experimental distribution curve fits the theoretical one very

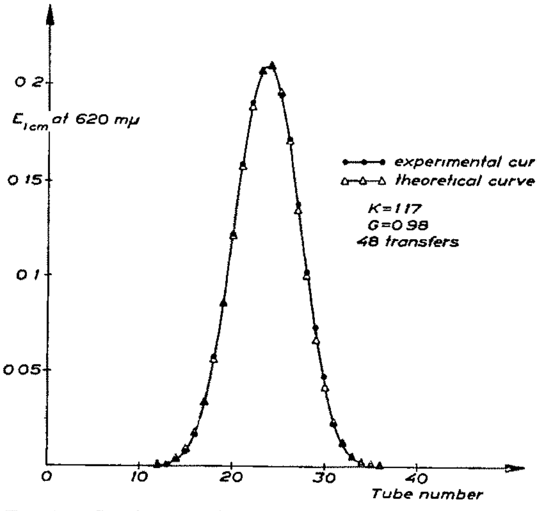

Fig 2 Counter-current distribution of phycoerythrin in a dextran–polyethylene glycol system containing 0 005 mole potassium monohydrogen phosphate, 0 005 mole potassium dihydrogen phosphate and 0 022 mole potassium chloride per 976 ml of the phase system The first tube was charged with 28 2 mgm protein Extinction was measured for samples from the bottom phase diluted with equal weight of water The K value was determined experimentally and the G value (the amount of protein in the top phase divided by the amount of protein in the bottom phase) was calculated from the position of the maximum of the experimental curve

well, indicating that the partition coefficient of the proteins in this phase system is a true Nernst partition coefficient. The salt mixture which would give a large separation factor necessary for the separation of phycoerythrin and phycocyanin could also be selected from the curves of Fig 1. Thus a salt concentration of 0·01 mole potassium phosphate and 0·75 mole potassium chloride per kgm. phase system was used in the experiment depicted in Fig 4. The *K*-value was determined experimentally for each tube. These are plotted in Fig 4, where it may be seen that while the *K*-value is fairly constant for phycocyanin it increases with the tube number for phycoerythrin, indicating heterogeneity for the latter protein. Such heterogeneity is also known from chromatography on calcium phosphate[21]. Heterogeneity could not, however, be revealed by precipitation tests according to Ouchterlony[22] since the phycoerythrin of the front and the trailing part of the peak gave identical reactions.

The proteins studied here are coloured and could easily be measured by their strong absorption in the visible spectrum. For uncoloured proteins the estimation of protein concentrations is more tedious. Thus, before measuring the ultra-violet absorption at 280 mμ the phases have to be diluted two to three times and then cleared by high-speed centrifugation for a few minutes. Even then it is sometimes difficult to get reproducible values when a small amount of protein is present. The dextran and polyethylene glycol interfere in the method of protein determination according to Lowry *et al.*[23] The biuret method[24] works for the polyethylene glycol-rich top phase. Nitrogen determination according to Kjeldahl may be used but this is rather time-consuming when many samples have to be analysed. A simple and rapid modification of these methods for protein estimation in a dextran–polyethylene glycol system is therefore needed.

There is no general method like, for example, dialysis for removing the polymers from the protein. On the other hand, there are so many other possibilities for achieving this purification that for a given protein a suitable method may usually be selected. Two ways in which phycoerythrin was recovered may serve as examples.

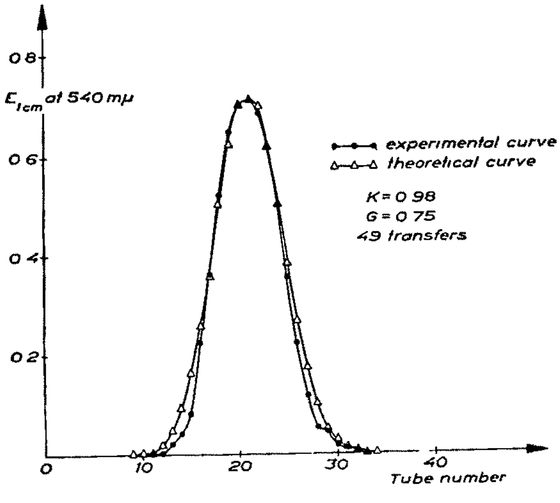

Fig 3. Counter-current distribution of phycocyanin in the same system as in Fig 2. The first tube was charged with 7 ml. of a solution of phycocyanin with an extinction of 20·3 when measured at 620 mμ in a 1-cm. cell. The *K* and *G* values indicated were obtained as in Fig 2

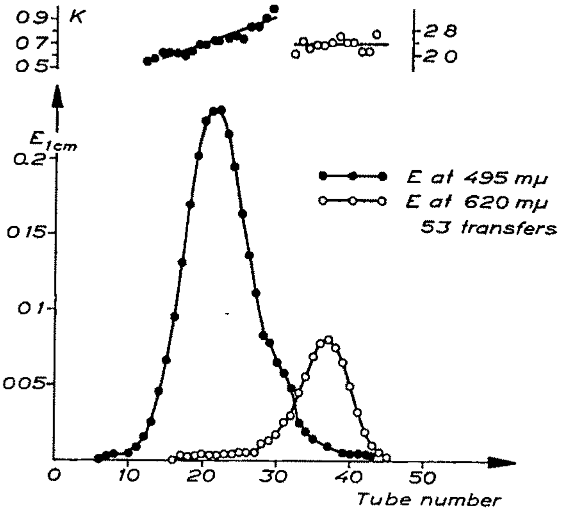

Fig 4. Counter-current distribution of a mixture of phycoerythrin (filled circles) and phycocyanin (open circles) in a dextran–polyethylene glycol system containing 0·005 mole potassium monohydrogen phosphate, 0·005 mole potassium dihydrogen phosphate, and 0·75 mole potassium chloride per 976 ml. of the phase system. The protein mixture was put into the first two tubes. The extinctions given are those of the top phase. The *K* values plotted above have been determined experimentally. The estimation of protein in the two phases was done by determination of the extinction at 495 mμ for phycoerythrin and the extinction at 620 mμ for phycocyanin

By the first method the mixture is passed through a column of calcium phosphate at 0·005 *M* potassium phosphate buffer (*p*H 6·8). The phycoerythrin is adsorbed while dextran and polyethylene glycol are not and they can therefore be washed away by the buffer. The phycoerythrin is then eluted with 0·1 *M* phosphate buffer. That the polymers had been washed away completely was checked by the anthrone method[25] for dextran and the method of precipitation of the barium derivative with phosphomolybdic acid for polyethylene glycol[26]. The presence of dextran and polyethylene glycol does not change the absorption capacity of calcium phosphate for phycoerythrin; it only reduces the time of flow.

The second method involves the following procedure: ammonium sulphate is added to 1·1 l. of a mixture containing the phycoerythrin, 3·5 per cent (w/w) dextran, and 2·2 per cent (w/w) polyethylene glycol until a concentration of 1 *M* is obtained. A top phase of 70 ml. is formed and contains all the phycoerythrin. It is dialysed against a 30 per cent (w/w) solution of polyethylene glycol containing 0·1 *M* sodium chloride and then added to 17 gm. of a 30 per cent (w/w) solution of a low molecular weight fraction of dextran (viscosity number 0·05). The phycoerythrin is almost entirely transferred to the small bottom phase of this system, which had a volume of 7 ml. and contained no polyethylene glycol. This phase is collected, dialysed, and the protein precipitated by the addition of ammonium sulphate.

All these procedures for the recovery of the protein have the advantage that the protein is concentrated into a small volume, a step which is often desirable prior to further purification or analysis.

We wish to thank Prof. A. Tiselius for his stimulating interest in this work, and Dr. L. Philipsson of the Institute of Hygiene and Bacteriology, Uppsala, for carrying out the immunological tests. The work has been aided financially by grants to the Institute of Biochemistry, Uppsala, from the Swedish Technical Research Council and from the U.S. Department of the Army through its European Office, under contract number *Da*-91-508-*EUC*-287 One of us (E J N) wishes to thank the Ministry of Education, Belgium, for a grant

PROPERTIES AND INHERITANCE OF HÆMOGLOBIN BY ASYMMETRIC RECOMBINATION

By DR. HARVEY A ITANO and ELIZABETH ROBINSON

National Institute of Arthritis and Metabolic Diseases of the National Institutes of Health,
Bethesda, Maryland

A MOLECULE of human adult hæmoglobin, which contains two types of polypeptide chains designated the α- and β-chains[1], dissociates into subunits α_2 and β_2 in dilute acid and re-associates to the native molecule $\alpha_2\beta_2$ in neutral solution[2,3] (A different nomenclature has been used in previous publications (refs 2, 4 and 5) Identification of the aberrant chain of hæmoglobin *S* (refs 7 and 8) permits adoption of a uniform nomenclature based on the proposal of Rhinesmith, Schroeder and Martin (ref 1) A comparative chart of the two systems of nomenclature has been given elsewhere (ref 3) Recombination of an acid-dissociated mixture of two hæmoglobins that differ from each other in one of the two pairs of chains results in exchange of the sub-unit common to the two forms without formation of new molecular species[2,4] Recombination of two hæmoglobins that differ from each other in both chains apparently results in formation of new molecular species[5]

The effect of recombining two hæmoglobins that differ in both chains has been observed in the present work with mixtures of human carbonmonoxyhæmoglobin *A* and canine carbonmonoxyhæmoglobin Acidification of equimolar mixtures of these hæmoglobins to *p*H 4 7 followed by neutralization[4] yielded two new electrophoretic components in addition to the original components (Fig 1) The absorption spectrum of the recombined mixture is the same as that of an untreated mixture Canine carbonmonoxyhæmoglobin migrates more slowly than carbonmonoxyhæmoglobin *A* at *p*H 6 8 One of the new components migrates more rapidly than *A* and the other migrates more slowly than the canine form The relative mobilities of these new components and increase in their proportions with time of exposure to dilute acid (Table 1) are consistent with the occurrence of a relatively slow exchange reaction in which mixed molecules are formed The net change (formation of new species at the expense of the original components) may be represented by the reaction

$$\overset{A}{\alpha_2}\overset{A}{\beta_2} + \overset{\text{can.}}{\alpha_2}\;\overset{\text{can}}{\beta_2} = \overset{A}{\alpha_2}\overset{\text{can}}{\beta_2} + \overset{\text{can}}{\alpha_2}\;\overset{A}{\beta_2}$$

(The α and β polypeptide chains of human hæmoglobin have been defined according to their N-terminal amino-acid sequences (ref 1) Since these sequences are not known for canine hæmoglobin, our use of this terminology here depends upon the fact that the chains of canine hæmoglobin appear to be configurational analogues of the α- and β-chains)

Table 1 COMPOSITION OF CANINE AND HUMAN HÆMOGLOBIN MIXTURES BEFORE AND AFTER RECOMBINATION

Dissociation time	Electrophoretic composition per cent of total*			
	New slow	Canine	*A*	New fast
Control	—	41	59	—
20 min	10	36	44	10
40 min	11	39	39	11
4 hr	22	28	32	18
22 hr	31	24	21	24

* All samples contained 50 per cent each of human and canine hæmoglobin before recombination Percentages shown are probably anomalous because of low concentration of buffer-ion

Vinograd, Hutchinson and Schroeder[6] and Ingram[7] have shown that the β-chain is the aberrant chain of hæmoglobin *S*, and Hunt and Ingram[8] have shown that the inherited amino-acid substitutions of hæmoglobins *S* and *C* occur in the identical chain position Recombination with hæmoglobins *S* and *C* of hæmoglobins *D*, *E* and *J* from families previously reported by one of us[9,10] resulted in no significant change in electrophoretic composition A component migrating between hæmoglobins *A* and *I* appeared when hæmoglobin *I* from the family reported by Rucknagel, Page and Jensen[11] was recombined with hæmoglobin *S* (Fig 2) Changes in composition were also observed when Hopkins-2 hæmoglobin[12] was recombined with hæmoglobins *S*, *C* and *J*.

No evidence of recombination was obtained from acidification and neutralization of mixtures of bovine carbonmonoxyhæmoglobin *A* (ref 13) with human carbonmonoxyhæmoglobin *A*, canine carbonmonoxy-

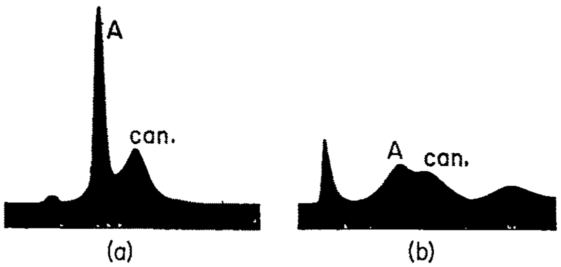

Fig. 1. Ascending limb electrophoretic patterns of 1 per cent carbonmonoxyhæmoglobin in phosphate buffer of *p*H 6.8, $\Gamma/2$ 0.02. The direction of migration is from right to left. (*a*) *A*, canine control. (*b*) *A*, canine recombined after 4 hr. dissociation at *p*H 4.7

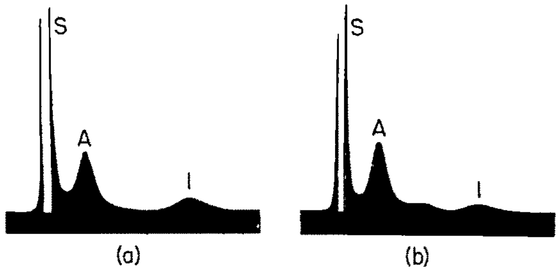

Fig. 2. Ascending limb electrophoretic patterns of 1 per cent carbonmonoxyhæmoglobin in phosphate buffer of *p*H 6.3, $\Gamma/2$ 0.02. The direction of migration is from right to left. (*a*) *S*, *A*, *I* control. (*b*) *S*, *A*, *I* recombined

hæmoglobin or bovine ferrihæmoglobin *A*. Human and canine carbonmonoxyhæmoglobins, which recombine with each other, also recombine with their respective ferrihæmoglobins to form an intermediate component. The postulated structure of this component, a molecule with two carbonmonoxyhæms and two ferrihæms, is the same as that of an intermediate compound in the oxidation of carbonmonoxyhæmoglobin to ferrihæmoglobin[2,14]. Although it is possible that sub-units of one hæmoglobin would be physically incompatible with those of another[4], it is not likely that sub-units which differ only in the chemical state of the hæms would be incompatible. Therefore the absence of an intermediate component in an acidified and neutralized mixture of the carbonmonoxy- and ferri- forms of bovine hæmoglobin indicates in all probability that the acidified mixture does not contain sub-units, that is, that bovine hæmoglobin, unlike human and canine hæmoglobins, does not dissociate at *p*H 4.7. This conclusion is consistent with other evidence of structural stability of the bovine hæmoglobin molecule, namely, its extremely high resistance to alkali denaturation[15].

These experiments suggest several applications of the recombination method. Reversible dissociability of a hæmoglobin under specified conditions can be tested by subjecting a mixture of its carbonmonoxy- and ferri- forms to these conditions. The altered chain of a dissociable abnormal hæmoglobin can be rapidly identified by electrophoretic analysis after recombination with a previously characterized dissociable form such as hæmoglobin *S*. Change in electrophoretic composition will presumably occur if the abnormal hæmoglobin dissociates reversibly and differs from hæmoglobin *S* in both chains; but no change will occur if it is abnormal only in the β-chain, the abnormal chain of *S*. Although some of our samples have not been tested for dissociability, the results in comparable cases agree with those obtained by Ingram[7] by chemical analyses. The donors of hæmoglobin *I* of our earlier report[5] and the present investigation are not known to be related. Both have mixtures of hæmoglobins *A* and *I* in their red cells; however, the proportions of *I* are different, about 60 and 20 per cent, respectively. The result in each case points to an α-chain defect in hæmoglobin *I*. The occurrence of an exchange reaction between human and canine hæmoglobins shows that these hæmoglobins have similar configurations at the surface of union of their respective sub-units in spite of large differences in amino-acid composition[16]. Isolation and chemical characterization of mixed molecules produced by recombination will permit identification of the chains in canine and other dissociable hæmoglobins that are configurational analogues of the α- and β-chains of hæmoglobin *A*.

According to Smith and Torbert[12], the gene controlling Hopkins-2 hæmoglobin segregates independently of that controlling hæmoglobin *S*. The changes observed in recombined mixtures containing Hopkins-2 hæmoglobin were small because the proportion of this form in the original sample, a mixture of *A* and Hopkins-2, was low. Nevertheless, the results in several experiments were always consistent with abnormality in the α-chain of Hopkins-2 hæmoglobin. Our results to date, together with the familial data of Smith and Torbert, are thus in accord with independent genetic control of the α- and β-chains. The hæmoglobin of double heterozygotes for *S* and Hopkins-2 has only three electrophoretic components, identified as *S*, *A* and Hopkins-2 (ref. 12), although random association of two different α-chain pairs and two different β-chain pairs, each of which is independently synthesized, would yield four molecular species. The fact that *S* and Hopkins-2 have opposite charge abnormalities with respect to hæmoglobin *A* may account for the apparent inconsistency. A molecule composed of abnormal β-chains from *S* and abnormal α-chains from Hopkins-2 would have approximately the same net charge as *A* and would not separate electrophoretically from *A*. The same mechanism has been proposed to explain the presence of only three electrophoretic components in recombined mixtures of hæmoglobins *C* and *I* (ref. 5).

A more detailed report of this work will be published. We are indebted to Dr. Ernest W. Smith for the sample of Hopkins-2 hæmoglobin.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, December 7

Institution of Electrical Engineers, Electronics and Communications Section (at Savoy Place, London, W C 2), at 5 30 p m —Mr B B Jacobsen "Frequency Patterns for Multiple-Radio-Channel Routes"

University of London (at King's College, Strand, London, W C 2), at 5 30 p m —Prof Max Derruau (University of Clermont-Ferrand) First of three lectures on the "Central Massif of France" * (Further lectures on December 8 and 10)

University of London (at Queen Mary College, Mile End Road, London, E 1), at 5 30 p m —Dr M Eigen (Max-Planck-Institut fur Physikalische Chemie, Gottingen) "Relaxation Spectra of Fast Chemical Changes in Solution" *

Manchester Literary and Philosophical Society (in the Reynolds Hall, Manchester College of Science and Technology, Sackville Street, Manchester), at 5 45 p m —Dr J Needham, F R S "Hydraulic Engineering and Society in Ancient and Medieval China" (Wilde Memorial Lecture)

Society of Instrument Technology (at Manson House, 26 Portland Place, London, W 1), at 7 p m —Mr G Pask "Discontinuous Skill Teaching Machines"

Tuesday, December 8

Zoological Society of London (at the Zoological Gardens, Regent's Park, London, S W 1), at 9 45 a m —Symposium on "Cyclical Activity in Endocrine Systems"

Society of Chemical Industry, Agriculture Group (at 14 Belgrave Square, London, S W 1), at 10 30 a m —Dr T H Rose and Mr P H Brown "Experiments Comparing a Number of Conditions for the Improvement of Glasshouse Soils", Mr J Webber and Mr F W Shepherd "Experiments Comparing Bulky Organic Manures for Horticultural Crops", Dr F Haworth "Fertilizer Responses of some Vegetable Crops"

Institute of Marine Engineers (at the Memorial Building, 76 Mark Lane, London, E C 3), at 5 30 p m —Mr A Lindén "Recent Development of the Gotaverken Engine"

University of London (at Queen Mary College, Mile End Road, London, E 1), at 5 30 p m —Dr M Eigen (Max-Planck-Institut fur Physikalische Chemie, Gottingen) "Proton-conducting H-bond Systems and their Analogies to Electronic Semiconductors" *

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 5 30 p.m —Dr L G Lajtha "Autoradiography in Bone Marrow Studies" (Fourteenth of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation *) (Further lecture on December 10)

Royal Aeronautical Society (at 4 Hamilton Place, London, W 1), at 7 p m —Dr E K Armstrong and Mr R E Stevenson "Some Practical Aspects of Compressor Blade Vibration"

Wednesday, December 9

University of London (at the Postgraduate Medical School of London, Ducane Road, London, W 12), at 2 p m —Dr J D N Nabarro "Laboratory Investigations in Endocrinology" *

Institute of Physics (at 47 Belgrave Square, London, S W 1), at 6 p m —Sir Edward C Bullard, F R S "Geological Time"

Society for Psychical Reesarch (at Leighton House, 12 Holland Park Road, London, W 14), at 6 30 p m —Dr Letitia Fairfield "Children and Witchcraft"

Oil and Colour Chemists' Association, London Section (at the Royal Society of Tropical Medicine and Hygiene, Manson House, 26 Portland Place, London, W 1), at 7 p m —Dr S H Bell "Electron Microscopy and Paint Technology"

Society for Analytical Chemistry, Biological Methods Group (at the Chemical Society, Burlington House, Piccadilly, London, W 1), at 7 p m —Annual General Meeting, followed by Dr H J Wallis, Mr S. S Kind and Dr A S Curry "Biological Methods in Forensic Science"

Women's Engineering Society (at "Hope House", 45 Great Peter Street, London, S W 1), at 7 p m —Dr Elizabeth Laverick "Radar and Telecommunications Research and Development"

Chemical Society (at Burlington House, Piccadilly, London, W 1), at 7 30 p m —Prof G H Cady "Some Recent Advances in Fluorocarbon Chemistry"

Wednesday, December 9–Friday, December 11

Crop Protection and Pest Control Exhibition (organized by *World Crops*, at the Seymour Hall, Seymour Place, London, W 1)

Thursday, December 10

Institution of Electrical Engineers, Utilization Section (at Savoy Place, London, W C 2), at 5 30 p m —Mr D B Corbyn and Mr N L Potter "The Characteristics and Protection of Semiconductor Rectifiers"

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W C 1), at 5 30 p m —Dr Sheila T Callender, "Iron Absorption" * (Last of the fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation)

Thursday, December 10–Friday, December 11

British Institute of Radiology, incorporated with the Rontgen Society (at Church House, Westminster, London, S W 1)—Annual Congress and Exhibition

Royal Society (at Burlington House, Piccadilly, London, W 1), at 9 30 a m daily—Discussion on "The Biology of the Southern Cold Temperate Zone" opened by Prof C F A Pantin, F R S

Friday, December 11

Royal Aeronautical Society (at the Institution of Mechanical Engineers Birdcage Walk, Westminster, London, S W 1) —Symposium on "Flight Safety" (All Day Discussion)

University of London (at the Postgraduate Medical School of London, Ducane Road, London, W 12), at 4 p m —Prof A Haddow, F R S 'The Present and Future Relationship of Cancer Research to Medicine"

Institute of Physics (at 47 Belgrave Square, London, S W 1), at 6 p m —Mr J F Sayers "The Ultrasonic Camera—an Alternative Approach to Ultrasonic Testing"

Institution of Electrical Engineers, London Graduate and Student Section (at Savoy Place, London, W C 2), at 6 30 p m —Sir Willis Jackson, F R S "The Trends of Electrical Progress and Their Implications"

Royal Aeronautical Society, Agricultural Aviation Group (at 4 Hamilton Place, London, W 1), at 7 p m —Mr Peter King "Aerial Operations Planning in the United Kingdom —Results and Difficulties"

Royal Institution (at 21 Albemarle Street, London, W 1), at 9 p m —Prof R E D Bishop "The Menace of Vibration in Engineering"

Saturday, December 12

London County Council (at the Horniman Museum, London Road, Forest Hill, London, S E 23), at 3 30 p m —Mr Philip Hunter-Jones "The Desert Locust" *

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Lecturer in Mathematics in St Salvator's College—Joint Clerk to the University Court, College Gate, St Andrews (December 31)

Lecturer (with a special knowledge of, and an interest in, the vertebrates) in Zoology—The Registrar, King's College (University of Durham), Newcastle-upon-Tyne 1 (December 31)

Librarian (graduate, with a recognized library qualification, and preferably experience in a University, College or Technical Library)—The Principal, Coventry Technical College, Butts, Coventry (December 31)

Senior Lecturer (with a degree in chemical engineering or applied and industrial chemistry or with experience in the practice of chemical engineering in industry and/or in teaching and research) in Chemical Engineering at the University of Cape Town, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (South Africa, December 31)

Technician (preferably with experience in a laboratory concerned with physiology, biochemistry, or the culture of micro-organisms) in the Botany Department, University of Canterbury, New Zealand —The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (December 31)

Senior Lecturer (with main interest and special qualifications in the field of petrology) in Geology at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (Australia, January 4)

Lecturer in Veterinary Anatomy at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W C 1 (Australia, February 27)

Head (graduate, with extensive experience of seed production, preferably including practical farming) of the Multiplication Branch—The Secretary, National Institute of Agricultural Botany, Huntingdon Road, Cambridge

Qualified Technician (with the Diploma in Chemical Pathology Technique) at Launceston General Hospital, Tasmania—The Agent General to Tasmania, 457 Strand, London, W C 2

UNDER-DEVELOPED TERRITORIES AND THEIR PROBLEMS

IN his presidential address to the British Association in Dublin in 1957, Prof P M S Blackett directed attention to the steadily widening gap between the Western countries and those of Asia and Africa, and advocated a loan of £1,000 million a year, in addition to commercial and short-term government lending either as a free gift or as long-term loans Britain's share of this would have amounted to £150 million a year Although the problem of aid to the under-developed countries has since been widely discussed in all its aspects, it was admitted by the Secretary of State for Foreign Affairs, Mr. Selwyn Lloyd, in a broadcast on United Nations Day (October 24), that the rapid rise in the standard of living in the highly developed countries is not being matched by improvements in those less developed For that reason, he said, the Government will support the work of the United Nations Special Fund to finance large-scale schemes of economic development in such countries, and Parliamentary approval is to be sought to increase five-fold the British contribution to that fund—a contribution at present standing at a million dollars

It should be noted that Mr P Hoffman, director of the Special Fund, has already proposed that the objective should be to double the increase of income a head in the under-developed countries during the next ten years On the calculations of a report of M. J Monnet's Action Committee for the United States of Europe, which called on the Common Market countries to adopt a common policy on economic aid to such countries, this would require doubling the amount of capital supplied to the under-developed countries by the outside world, and the figure of 7,500 million dollars annually is about equivalent to 1 per cent of the combined national income of the richer countries—rather less than the proportion represented by the United Kingdom's estimated total contribution to the development of these countries in 1958–59 of £2 15 million It should, of course, be remembered that, apart from assistance given under the Colombo Plan and under the Colonial Development and Welfare Acts, Britain is contributing in various ways to economic and technical assistance, and in its development fund for overseas territories, the European Economic Community has launched a programme of capital investment in French and Belgian African territories, while, besides its existing massive contribution of some 16,000 million dollars, the United States is being urged by the Senate Foreign Relations Committee to consider a more generous policy to Africa based on the human need to raise standards of living.

One of the biggest obstacles here is the rapid increase in population in those countries, and although the York meeting of the British Association did not give anything like as much attention to the under-developed countries as was done at Dublin, Dr L Harrison Matthews's forthright assertion attracted wide attention In his presidential address to Section D (Zoology), Dr Harrison Matthews declared that the most serious problem at present facing the human race is the frightening rate of increase of population, especially in the so-called under-developed parts of the world. Past and present experience, he said, gives no grounds for complacency, there will be no room to produce food, or indeed anything else, far less to conserve fauna, if there is one person on every square yard

This stern warning that uncontrolled increase in population inevitably builds up to a crash, which incidentally included a strong plea that we should welcome any offer of co-operation from the United States in conservation and like matters in Africa and elsewhere, has been strongly supported in a Friday Evening Discourse which Sir Norman Kipping, director-general of the Federation of British Industries, delivered at the Royal Institution on October 23 Sir Norman believes that one of the two hopes for a real advance in the material standards of the under-developed world lies in a simple, cheap and fool-proof method of birth control, which will give India, Egypt and China a breathing space for their output to catch up and run ahead of their expanding populations His other major hope lies in the development of cheap and simple 1,000 kVa nuclear-fuelled power stations Cheap and plentiful power means, among many other things, he pointed out, water which would be pumped and piped from as far as necessary or distilled from the sea.

Sir Norman showed himself much more aware than many speakers on this subject of the magnitude of the effort which the United Kingdom is already making · in personal terms, we are spending on technical assistance annually about 17*s* 8*d* a head, and, including private investment, which accounts for about half, our total contribution to the development of the under-developed countries is already rather more than 1 per cent of our gross national product Even against the 4,500 million dollars of outstanding loans at the World Bank, external assistance to the under-developed Colombo Plan countries in 1957–58 of more than 1,000 million dollars and United Nations Technical Assistance Administration expenditure of some 30 million dollars a year, this contribution is not to be disparaged, but it is right that Britain and other countries should ask themselves, as Sir Norman suggests, whether in scale or urgency such efforts measure up to the task, whether the full significance of the time factor is appreciated, and whether techniques could be improved The time factor, he recognizes, involves a dilemma, for many of the surest lines of advance involve long-term policies, and he admits that a policy of gradualness is a hard doctrine for many under-developed countries to appreciate

Much that Sir Norman said has frequently been emphasized in other connexions, for example, notably at the Commonwealth Trade and Economic Conference at Montreal in September 1958, though Sir Norman was concerned more particularly to indicate ways in which industry could render practical help. On one point, he strongly supported the views expressed recently by Mr. M. Ionides before the Royal Institute of International Affairs. Mr. Ionides had argued that Western institutions adapted to societies where the initiative comes from below cannot fully satisfy the needs of a society where the flow of initiative is from the top down. In particular, Western institutions are not organized to tap the immense capital resources in these countries already existing in the form of unused man-power. They can only touch the fringe where a cash economy exists. Frequently, by injecting the large-scale projects, we divert available enterprise and initiative from the much-needed widespread small-scale development, and without providing the means for this basic development. The large-scale project does not even teach the simple methods, or provide the required training in them, or, where it is needed, the organizing ability essential for a start.

Sir Norman Kipping elaborated this factor from a different angle, but was no less emphatic that the impetus must come from above—from the élite few in each country who are in contact with the outside world and have educated themselves in modern techniques, and from those from more advanced countries who have come to trade, to teach or to investigate. By and large, in these countries the springs of individual initiative and resource in economic matters have been lacking, and where there is a new awakening and determination the transition into the modern world is harder and more complicated than it was when European development began. This in itself largely accounts, as Sir Norman remarked, for the tendency to think in terms of the grandiose scheme at the expense of the equally important little schemes. It creates the further problem that the educated few tend, by the very fact of their education, to be cut off from the mass of their own people.

This is an aspect to be remembered in considering the functions and future of the Colonial Development Corporation. It is exactly in such a situation that new institutions are needed, new links with institutions in the more advanced countries, and, generally, a flexible and experimental approach. By its nature, the Corporation has always occupied a position between commercial enterprise and public works financed by taxation. It was enjoined, moreover, to have particular regard for the interests of the inhabitants of the countries in which it worked and not merely to pay its way.

The intertwining of social and commercial ends is naturally liable to cause difficulties and, while under Lord Reith's chairmanship much was done to bring the Corporation's affairs into good shape, in his last two years of office conflicts have arisen over policy and procedure, so much so that Lord Reith complained of frustration, and welcomed the establishment, in April 1959, of an independent investigation into the capital structure of the Corporation under the chairmanship of Lord Sinclair of Cleeve. The Committee interpreted its terms of reference—"to examine the functions of the Colonial Development Corporation within its existing statutory framework, and to consider whether any change in its financial structure is required, and to make recommendations"—as requiring it to determine whether or not the existing financial structure is suited to the fulfilment of the obligations laid upon the Corporation, and, if not, to show why and to state how it could be improved. Accordingly, the Committee began by examining the existing functions of the Corporation in the context of the changing circumstances in which more government funds are being made available both under the Colonial Development and Welfare Acts to the decreasing area of the Colonies, and by means of Commonwealth Assistance loans under the Export Guarantees Act, 1949 and 1957, to the former Colonies but now independent territories.

The wider interest of the Committee's report* arises from this preliminary examination, which appears thoroughly to justify Lord Reith's protests. The territorial scope of the Corporation's activities is diminishing, and particularly in territories which by reason of their stage of economic development would have offered more immediate scope for the Corporation's activities. The Committee unhesitatingly concludes that it is not possible for the Corporation to continue to carry out the purposes for which it was set up, and at the same time meet the obligations laid upon it under the Act, unless there is an immediate change either in its financial structure or in the nature of its activities. If it is desired that the Corporation should carry its existing commitments and, still more, should continue to invest in projects involving a considerable degree of risk, the existing financial structure must be amended to one more compatible with the nature of the Corporation's operations, and the Committee's financial recommendations are to that end.

The detailed recommendations need not be considered here, but it should be noted that although the Sinclair Committee believes that its recommendations will both ensure that the Corporation's true financial position will be more easily deducible from the accounts from year to year, and also help to prevent what would otherwise become an intolerable burden undermining the good the Corporation has done or could do, it points out that no modifications to the financial structure can by themselves transmute what is clearly a very difficult operation into an easy or highly successful one. Parliament must be clear as to what exactly the Colonial Development Corporation is intended to do. But the Sinclair Committee finds the claim valid that the Corporation is unique and essentially distinct from nationalized industries and public corporations

* Report of the Committee of Enquiry into the Financial Structure of the Colonial Development Corporation. Pp. iii+25. (Cmnd. 786.) (London: H.M. Stationery Office, 1959.) 1*s*. 6*d*. net.

operating in Great Britain. These are matters rather for the Corporation itself and the Colonial Office, but the Committee leaves no room for doubt that if Parliament wishes the Corporation to continue its efforts to assist economic development in the Colonial Territories, the ordinary rules for payment of interest and repayment of capital must be relaxed; otherwise the Corporation will ultimately be confronted with an annual obligation which it has no reasonable prospect of being able to meet.

The Sinclair Report should thus clarify thinking about both the Colonial Development Corporation and the British contribution to economic development overseas. Specifically, the Committee considers that the Corporation, under the existing Act, should be relieved of liability for interest unpaid at the date when abandonment of a project is approved, and that it should be left to the commercial judgment of the Corporation to decide when to realize on investment, bearing in mind that once a project has become firmly established and is benefiting the economy of the territory concerned, the primary purpose of the Corporation in initiating the project has been achieved. Later, the Committee reiterates the view that the question of accountability as affecting the Corporation is not in practice capable of sharp definition, and suggests that broadly the judgment whether a project is worth while on commercial grounds is primarily one for the Corporation, and the decision whether it is in accord with public policy and within the Act is for the Secretary of State.

In such circumstances it is the more important that questions of Colonial development and welfare and of assistance, whether economic or technical, to the under-developed areas generally should be discussed as free from party political prejudice as possible. The problems are too complex and difficult to be capable of easy solution even when all the facts can be ascertained beyond question. What matters is that discussion should be fully informed, and as free as possible from prejudice, and that programmes of action should be framed to take account of the social and educational difficulties, as well as those of technology, economics and finance. It is obvious that much preparation will be required, even when such discoveries or developments as those for which Sir Norman Kipping pleaded have taken place, before their results can be made available to the under-developed areas. Meanwhile, the more clearly the situation is understood, both in the advanced and the backward areas, and the more resolutely and urgently the United Kingdom and other advanced countries contribute towards meeting existing needs and filling available opportunities, the easier it should be to take full advantage of any fresh advance which will enable mankind to solve this threatening problem of unbalance between population and all its myriad needs and the material resources in food, in fuel, in energy and mineral wealth to satisfy them. Sir Oliver Franks remarked early this year that the under-developed countries cannot be free to embark upon development programmes regardless of their own resources, and then expect the industrial countries to underwrite them to an unlimited extent; and, on the other hand, for the developing countries to have any chance of raising their standards of living they must undertake capital development on a scale which is bound to make their demand for imports outstrip their ability to pay in exports for many years to come, quite apart from the population question. There, however, lies the real problem, and if the gap in living standards is to be closed and all its explosive possibilities removed, both understanding and a sense of urgency will be needed; the situation requires human sympathy as well as economic insight and the wise use of all instruments that come to hand.

NUMBERS OF PEOPLE

The Study of Population

An Inventory and Appraisal. Edited by Philip M. Hauser and Otis Dudley Duncan. Pp. xvi+864. (Chicago: University of Chicago Press; London: Cambridge University Press, 1959.) 112*s*. 6*d*. net.

THE counting of people is almost as old as man himself. Concern about numbers is old but not so old. The study of population as a narrow field of formal scientific inquiry goes back only three centuries. The recognition of the interdisciplinary character of the more embracing study of population in relation to space and resources is recent and not yet sufficiently widespread. An account of historical development linked with and supporting both a contemporary assessment of the status of demography as a science and an evaluation of the possibilities of its integration with other scientific disciplines has been needed for some considerable time. This need has now been met. Such a project is a formidable undertaking and the size of the resultant volume is also formidable. One wonders whether it was necessary to have separate chapters on the development of demography in different countries except as a concession to national pride. It would have been better to have a world review of significant developments shown in relation to the social and economic pressures which stimulated them. The editors, too, have spread themselves unduly in the introductory chapters. But it is all interesting and well written; and more ruthless editing would not have made the book much lighter.

Undoubtedly the general pattern of the book is right: four chapters on demography as a science; nine chapters covering historical development on a world-wide scale; twelve chapters on different sub-fields in demography; seven chapters on population studies in various disciplines (genetics, human ecology, sociology, anthropology, economics, geography); and, surely a blessing in so large a volume, the 'overflow and conclusions' form the subject of Chapter 1. The historical chapters make fascinating reading. The authors have succeeded in bringing to life the significant personalities and the raging controversies (of which the Malthusian is but one) of earlier days. The treatment of British demography by Prof. E. Grebenik is balanced and fair. It is sadly true that while considerable developments of technique were made by actuaries throughout the nineteenth century, formal teaching in British universities has lagged. This is mainly due to the lack of career outlets for demographers, the incentive to specialize being correspondingly small Perhaps, however, there should be less specialization In those vast areas of the world where population growth presses so menacingly upon under-developed economies, pure demographers are less in demand than those with a wider and multidisciplined approach, an understanding of the subtle inter-relationships between demographic, geographical, ecological, social and economic factors Just how wide the field of knowledge must be is excellently illustrated in the closing chapters of this symposium Everywhere knowledge is incomplete Information concerning land and other resources, the effect of locational factors, genetic changes and biological influences, cultural forces, and the manner of community expansion and reorganization—all this now concerns the population student

If any part of the book is to be criticized, it is the form and content of the middle chapters This is not a question of factual or expository deficiency, for authorship is of a very high standard One gets the impression of a little too much erudition, particularly too much factual content, and not enough concentration upon methods of measurement The chapter on population distribution criticizes the descriptive and one-sided character of contemporary studies, but appears to favour methods of multiple regression analysis which succeed only to the extent that they are descriptive, and are in disrepute because they have built-in hazards of interpretation It ignores the volumetric approach of the geographer The fertility chapter affords little space to the index problem in measurement and concentrates more on the subject of fertility regulation ; on the other hand, the chapter on population replacement is largely confined to methods of arithmetic with barely enough interpretative caution But it must be admitted that it is always difficult to decide how much space to allot to explaining how to measure and how much to discussing the essential character of the events that are being measured The book is claimed to be an encyclopædic summary It is a difficult feat of editorship to prevent this from being a contradiction in terms and the editors are to be congratulated on a very high measure of success This is more than a reference book , it will attract sustained study

STERIC EFFECTS IN ORGANIC MOLECULES

Steric Effects in Conjugated Systems

Proceedings of a Symposium held at the University, Hull, 15–17 July, 1958, by the Chemical Society Edited by Dr G W Gray Pp viii+181 (London Butterworths Scientific Publications , New York Academic Press, Inc , 1958) 30*s*

THIS relatively inexpensive book is a useful addition to the small number of books concerned with steric effects in organic molecules It contains the fifteen original papers, together with 44 pages of ensuing discussion, which were read at the symposium held in Hull during July 15–17, 1958

A lucid historical survey by E E Turner was followed by seven papers in which the relationship between the light absorption and the conformation of conjugated systems was discussed The theoretical treatments of C A Coulson and of W F Forbes were accompanied by papers by G H Beaven, C C Barker, and by E S Waight and R L Erskine, incorporating detailed measurements of the spectra of numerous alkyl diphenyls, di- and tri-phenylmethane dyes, and conjugated carbonyl compounds, respectively Certain spectral data were related to rates of reaction and the pK_a by B M Wepster, though the author pointed out that this approach is not universally applicable

Attempts to evaluate steric and electronic effects with the aid of kinetic data were described in four papers The rates of nucleophilic aromatic substitution, of the solvolysis of aralkyl halides, of the acid-catalysed H–D exchange in aromatic hydrocarbons, and of a variety of reactions involving *ortho*-substituted compounds were discussed, respectively, by N B Chapman, H C Brown, G Dallinga *et al* , and A C Farthing and B Nam

The remaining papers illustrated the application of other physical methods A paper by E A Johnson on the gas-liquid chromatography of alkyldiphenyls provided an interesting complement to that by Beaven Contributions by J W Smith and by G W Gray described dipole moment measurements and observations on mesomorphism, respectively

In summary, this collection of original papers embodying review material and some discussion provides a valuable survey of contemporary studies concerning the conformations of conjugated molecules.

COLORIMETRY

Colorimetric Methods of Analysis, including Photometric Methods

Vol 2A By Dr Foster Dee Snell and Dr Cornelia T Snell, assisted by Dr Chester Arthur Snell Pp x+793 (New York D Van Nostrand Company, Inc , London D Van Nostrand Company, Ltd , 1959) 112*s* 6*d*

THE volume under review supplements the data given in the third edition (1948–54) of Volume 2, and includes all the important publications which have appeared prior to January 1956 In dealing with such a vast compilation, now five volumes, the authors cannot from their personal experience recommend any particular method, and the question arises as to whether treatises such as this have a universally useful function The answer appears to be that this treatise has been compiled by a team of experienced abstractors who can consult their own analytical department, and who are thus well able to judge whether a method merits recording or not

The scheme adopted throughout the volume is both logical and helpful to the reader Each chapter is headed by a brief description of new and useful additions to the methods described in the previous edition of Volume 2 Where the method is the result of collaborative study by a number of laboratories it is frequently given almost in full Thus the reader can proceed with such a method in confidence, knowing that it has been tested in a number of independent laboratories, and has justified its publication by a representative body of experts While this results in recording methods which have proved sound, these methods may not be the best available even shortly after publication, since collaborative studies between widely separated laboratories are necessarily very time consuming

One of the most useful new features in the volume is the prominence given to the use of flame photometry and fluorimetry. As stated in the preface, the improvements in burners and the application of photomultiplier tubes have greatly increased the sensitivity of the flame photometer, and improved tubes that of the fluorimeter. It would have been helpful if the general principles of the improved methods both for flame photometry and fluorimetry could have been described as a separate chapter, but presumably these will follow in a supplement to Volume 1. Without such help it may be puzzling to understand why on page 471 an oxy-acetylene burner is recommended for the determination of the alkali metals, but a propane-air burner on page 475. Much depends on the concentration of interfering elements and on the choice of internal standards. While such standards are desirable, their use may be attended by difficulties, since the optimum burner temperature for development of the colour of the test element may be far removed from that of the standard. What is required is not merely high sensitivity, but also uniform light emission with varying temperature. As a useful alternative to flame photometry for the determination of lithium, the application of fluorimetry is described, the sensitivity being such as to make as little as 0·005 mgm. determinable in the presence of limited amounts of sodium and potassium.

The amount of new material described in Volume 2A is astonishing, bearing in mind the short interval of time which has elapsed since the publication of Volume 2, and the original treatise of four volumes cannot be considered complete without Volume 2A. The references have been carefully chosen from an extremely wide selection of the world's scientific journals, and unlike some U.S.A. publications have no bias in favour of American work. J. KING

STATISTICAL METHODS

Principles of Statistical Techniques

A First Course, from the Beginnings, for Schools and Universities. By P. G. Moore. Pp. viii+239. (Cambridge: At the University Press, 1958.) 22s. 6d. net.

IN the Preface to this excellent text-book the author claims that it is "... an attempt to put across the main principles of statistical methods ...". This claim is abundantly justified. The book is readable from start to finish, and only in Chapters 10 and 11 (dealing with tests of significance) will more than normal concentration be needed, even if the reader is approaching the subject for the first time. The book will be a valuable addition to every grammar-school library. Many sixth form pupils, especially those reading geography or economics, will derive great benefit from a careful study of it; in the field of general studies, however, it will appeal to a much wider audience so that merely a single reading will help towards a clear understanding of the part which observation and sampling now play in pure research and in industrial investigations.

The author's style is attractive and the reader is led easily through chapters on the collection, tabulation and representation of data, frequency distribution and dispersion, to a careful study of the power (and the weaknesses) of sampling. The application of the binomial series and time series, together with a rather more technical consideration of significance, bring the student to a treatment of regression. The printing, tabulation and graphs have the excellence normally associated with the Cambridge University Press and there are few misprints. Important among these is the misuse of $\sqrt{npq}$ for $\sqrt{(npq)}$ in a number of places, and the same error is found (p. 160) in the formula

$$s=\sqrt{\frac{1}{n}}\Sigma(x-\bar{x})^2$$

At the end of each chapter there is a good set of exercises, but the value of these is greatly reduced by the absence of answers. It is to be hoped that the author will remedy this by a pamphlet until another edition is available. With this one serious reservation the book may be recommended warmly to anyone who needs to know, either for practical purposes or as a matter of general interest, how the analysis of observations can be accomplished. W. J. LANGFORD

PERCEPTION AND LEARNING

Dynamics of Behavior

By Prof. Robert S. Woodworth. Pp. x+403. (London: Methuen and Co., Ltd., 1958.) 36s. net.

PROF. WOODWORTH began his scientific career some sixty years ago with an admirable little book on movement, written in French. He afterwards worked with Sherrington on pseudo-affective reflexes and seemed well set to develop American psychology along experimental and physiological lines. Yet leadership in research somehow eluded him. The initiative passed to others, in particular Lashley, and it was left to Prof. Woodworth to provide the text-books on which successive generations of psychology students in the United States have been nourished. Plain fare, perhaps, but wholesome.

The present volume has its origin in the author's "Dynamic Psychology", first published in 1918. But it is far less a revision of the earlier book than the substance of a lecture course based upon it and progressively developed by Prof. Woodworth over the past forty years. The content ranges from reflexes to reasoning, the greater part being concerned with perception, motivation and learning conceived in terms of biological adaptation. Although the eclectic point of view will be familiar to readers of Prof. Woodworth's earlier texts, the present volume has the advantage of bringing together a great deal of experimental material, much of it recent, relevant to the general analysis of behaviour. It also provides a useful guide to the many, and often conflicting, theories of learning which have been evolved by American psychologists during the past thirty years. This is the kind of thing which he can do very well.

Prof. Woodworth demonstrates that his capacity to expound contemporary points of view in psychology has been in no way dimmed by advancing age. At the same time, his account of modern work perhaps suffers from the lack of any well-defined point of view of his own. Had the author held fast to his Sherringtonian origins and attempted to develop a theory of behaviour along evolutionary and physiological lines, it is possible that some real clarification might have been achieved. As it is, we have to make do with a somewhat ill-assorted conglomeration of facts and theories, imperfectly related one to the other, and the whole scarcely warranting treatment as a scientific discipline. Although it may be objected that this picture truly reflects the existing state of psychology, it might seem a pity to enshrine it in a formal text.

A contribution more limited in scope, tauter and more incisive in argument, would have served the purpose better

The author's style betrays a certain trans-Atlantic homeliness that may cause some elevation of English eyebrows Thus the reader is urged to "get acquainted with gravitation" much in the same way as he might be advised in other quarters to make friends and influence people It may also be surmised that the prevailing emphasis upon "outgoing human tendencies" owes more to American culture than to the scientific study of man

It is encouraging to note that Prof Woodworth retains something of his interest in the European scene Although ethology appears to have escaped him, British work in experimental psychology is exceptionally well represented O L ZANGWILL

NUCLEAR ENERGY AND ANALYSIS

Analytical Chemistry

Vol 1 Edited by M T Kelley (Progress in Nuclear Energy, Series 9) Pp vi+372+xii (London and New York Pergamon Press, 1959) 105*s* net

THIS volume consists of a collection of some of the papers of interest to analytical chemists which were presented at the Second International Conference on the Peaceful Uses of Atomic Energy held at Geneva in 1958 These papers have already been made available in Vols 3, 19 and 28 of the records of the Conference published by the United Nations, and this new book simply presents the material in a single volume of a more convenient size The papers have been arranged in five groups as follows: "Reactor Applications", "Activation Analysis", "Spectrographic Technique", "Industrial Applications", and "Health Physics" All papers are in English with the exception of two which are in French The reason for not publishing a complete volume in English is not clear, especially since these two papers are available in English in the United Nations publications

The first group of papers contains one giving the Harwell experiences in analytical chemistry work connected with reactors Two excellent review papers are also included, one dealing with most aspects of the analytical chemistry of thorium and the other on chemical methods for the determination of uranium in ores and associated materials In the activation analysis section, much information is given about Canadian and United States experiences with this valuable technique for trace determinations, especially when used in conjunction with γ-spectrometry A notable omission from this section is the excellent paper by Smales and co-workers reporting British experiences with this technique; this paper is available in Vol 2 of the United Nations publications

Other papers of note in the remaining sections deal with the use of infra-red spectroscopy for determinations connected with the use of heavy water in atomic energy work, and the use of non-destructive X-ray spectroscopy for the analysis of reactor fuel components Fassel's spectrographic method for the determination of gases in metals is also described In the section on "Industrial Applications", developments in the analytical services given to the programmes of the Industrial Groups of the U K Atomic Energy Authority are described Other papers deal with the use of radioisotopes in Japanese industry and the determination of tungsten in steels by employing the back-scattering of β-particles

The editing of this book could have been better and the index should have been more detailed A price of 5 guineas for a book of this type is very high

G W C MILNER

NORTH AMERICAN MAMMALS

The Mammals of North America

By Prof E Raymond Hall and Dr Keith R Kelson Vol 1 Pp xxx+1–546+79 Vol 2 Pp viii+547–1083+79 (New York The Ronald Press Company, 1959) 35 dollars the set

THE North American continent has a rich mammal fauna (995 species according to this compilation), and it has also a relatively high population density of mammalogists, among whom Prof E Raymond Hall is one of the best known With Dr K R Kelson, he has completed the enormous task of bringing together the most up-to-date facts and opinions about the taxonomy and distribution of North American mammals in an excellent production

The costs of preparing the manuscript, with its 500 maps, 553 figures, and numerous line drawings, must have been high, even by New World standards The completed work is a monument, not only to Prof Hall's ability as a mammalogist, but also to his talent for raising funds from official sources

Prof Hall's attitude to the law of priority in nomenclature is regarded by some people as admirable, and by others as intransigent It is certain that the vast majority of zoologists will regret his following Hershkovitz in calling the Virginian deer *Dama*, in the face of the request by the International Commission on Zoological Nomenclature to 'freeze' the situation pending its decision If the change is accepted (and here we find it in what will be a standard work for generations), it means that the European fallow deer, known to all as *Dama*, must be called *Odocoileus* The Commission will most probably decide to use its plenary powers to preserve stability in this instance Likewise, the Commission is considering the question of the availability of Oken, 1815–16, "Lehrbuch der Naturgeschichte", and Morrison-Scott has asked it to validate, among others, the well-used names *Citellus*, *Vulpes*, *Panthera* and *Pan* Hall and Kelson have rejected Oken while the matter is still, so to speak, *sub judice*, and have made some regrettable changes

One is surprised to find Merriam's 78 species of bears still recognized, but this directs attention to the fact that the authors have not attempted to revise questions of status, but have put forward the views of the most recent workers on a group, even when those views are patently unsound Many changes in taxonomic status will occur, and many subspecies recognized here will disappear, but here they are, all clearly listed, and it is far preferable to summarily dismissing them as synonyms without explanation

Everyone will be able to find something to disagree with in such a large work as this, but on the whole the work will be welcomed by every worker on North American mammals It is essentially for the professional, and outside the United States will have limited sales, but purchase by every university is obligatory For zoologists in other countries the distribution maps alone are worth the price

PETER CROWCROFT

Synthesis of Linear Communication Networks

Vols 1 and 2 By Wilhelm Cauer Second edition edited by Wilhelm Klein and Franz M Pelz Translated from the German by G E Knausenberger (McGraw-Hill Electrical and Electronic Engineering Series) Pp xxxvi+866 (London McGraw-Hill Publishing Company, Ltd, 1958) 151s

THE classical work of W Cauer on network synthesis was first published in 1941 and has only now appeared in an English translation During the fourteen years since the death of Cauer there have been many developments in network theory which have been treated at length in a number of recently-published text-books But Cauer's work cannot be regarded as out of date nor is his book in competition with these modern American texts Rather is it one of those permanent collections of work from which modern theory derives

The first part of the book contains a thorough treatment of one-terminal pair and two-terminal pair networks along lines which have now become familiar The image-parameter network is treated in very great detail and considerable attention given to the design of filters In the second part, Cauer treats reactance networks in general and expands the theory of frequency band-separation networks, a subject neglected in most other works

An attempt is made to bring Cauer's work up to date by the inclusion of a 44-page appendix outlining the recent advances in network theory and presenting a classified bibliography containing about 450 references

Advanced Analytical Chemistry

By Prof Louis Meites and Prof Henry C Thomas With a chapter on Infrared Radiation by Prof Robert P Bauman Pp xi+540 (London McGraw-Hill Publishing Company, Ltd, 1958) 69s

MODERN thought in analytical chemistry centres largely in the field of instrumental or physico-chemical methods, this is reflected in the ever-growing number of text-books dealing with this subject, either alone or as part of a study of 'advanced analytical chemistry'

The present book, written by two authorities in the field of electrochemistry (as applied to analytical chemistry), is basically the outcome of seven years experience in teaching undergraduate and graduate students at Brooklyn Polytechnic and the University of North Carolina On reading this book one can only envy these students their courses of instruction

The book is divided into twelve formal chapters which take the reader from a short but excellent discourse on the nature of analytical chemistry to a similarly well-written account of ionic equilibria in solutions and then to a series of chapters dealing with selected methods of instrumental analysis These include *p*H and redox potentiometry, conductometry, polarography and amperometry, electrolytic methods, spectrophotometry (visible, ultra-violet and infra-red), radiochemistry and finally ion exchange and chromatography This part of the text is concluded by a chapter on the development of an analytical method, this unusual inclusion in a student text is commendable in that it illustrates admirably the nature of analytical chemical research A number of appendixes then interrupt the text and these are followed by a longish (116 pages) section devoted solely to about ninety practical applications of the methods discussed earlier

Unlike many books on this subject, the present one gives prominence to the theory of the methods, although unifying this theory with the practical exercises The instruments themselves are subordinated to the theory underlying their use and it is indeed refreshing to find that the student is taught the essentials of a method so well, often on simple instruments, that when he encounters a more elaborate instrument he can "confidently be referred to the manufacturer's instruction book for information on how to turn the knobs"

Much could be said about this book, but in the end the conclusion would be the same—an excellent book, and well worth study not only by students but also by research workers in analytical chemistry

W I STEPHEN

The Structure and Properties of Porous Materials

Proceedings of the Tenth Symposium of the Colston Research Society held in the University of Bristol, March 24th–March 27th, 1958 Edited by D H Everett and F S Stone Pp xiv+389 (London Butterworths Scientific Publications, New York Academic Press, Inc, 1958) 60s, 12 dollars

THIS is a collection of papers from the tenth Colston Research Symposium held in Bristol last year Its scope may be indicated by listing the authors Rideal, Barrer, Wynne-Jones, Kington, de Boer, Everett, Dacey and Fendley, Flood, Wiggs, Kiselev, Foster and Thorp; Schofield, Mougey, François-Rossetti and Imelik, Kavtaradze, Rance, King, Honeybone and Harris, Preston As the names indicate, the authors' interests range from almost pure physics to biology The verbal discussions are particularly interesting, and show a fair degree of cross-fertilization They have been taken from tape recordings, and the temptation to over-edit has been avoided A few staccato exchanges read like verbatim reports of cross-examination, and the flavour of the individual contributions has been retained The reviewer approves of this, though he can conceive that this approval will not be universally shared

Demographic Yearbook 1958

(Special Topic Marriage and Divorce Statistics) Pp viii+541 (New York United Nations, London H M Stationery Office, 1958) Cloth, 8 dollars, 57s, 34 Swiss francs Paper, 6 50 dollars, 46s, 28 Swiss francs

THE "Demographic Yearbook" of the United Nations continues to provide the basic data for the population of the world The 1958 issue which has recently been published shows the annual rate of increase of the world's population over the period 1950–57 to be sixteen per thousand Central America, with a rate of twenty-six per thousand, is increasing fastest, North-West Europe, with a rate of six per thousand, shows the slowest rate of increase Figures of births, deaths, birth-rates, death-rates and expectations of life are again included, but the special topic dealt with in this issue is the statistics of marriage and divorce Data on marriages, the ages of persons married, singly and in combination, and marriage- and divorce-rates are given for the various countries There is also an introductory chapter in which the uses of nuptiality statistics are discussed

The volume continues the standard of excellence that one has come to expect from its predecessors

SPIRAL AND OTHER GROWTH FORMS OF SYNTHETIC DIAMONDS: A DISTINCTION BETWEEN NATURAL AND SYNTHETIC DIAMOND

By PROF S TOLANSKY, F.R.S, and DR I SUNAGAWA
Royal Holloway College, University of London

IN our laboratory, we have, during the past fifteen years, examined the surface microstructures of many hundreds of fine natural diamonds, mainly octahedra and dodecahedra, using precision optical techniques In view of the importance of the screw dislocation theory of crystal growth, we have sought diligently for spirals on these diamonds but we have never yet found a single indication of the existence of a spiral on any of the several thousand faces examined Nor, so far as we know, has anyone else Our techniques are sufficiently sensitive to reveal spiral growth sheets of height even less than 10 A We find with natural crystals that octahedral faces invariably exhibit growth trigons, dodecahedral faces show striations, networks or elevated disks and cubic faces are extremely rough We are quite categorical about never yet having found a growth spiral on diamond, indeed, the only near resemblance to such was experimentally identified as a percussion mark, simulating in its crack directions a crude resemblance to a spiral

We have recently acquired some specimens of the micro-diamonds made synthetically by the General Electric Company of Schenectady, some kindly loaned by Dame Kathleen Lonsdale, of University College, London, and some by Dr Custers of Johannesburg These are being subjected to a detailed examination, using both interferometry and a particularly sensitive phase-contrast microscope, from Japan, which is at our disposal The new characteristics we describe here are shown by both samples They have not been reported before in the very extensive literature on natural diamonds We describe here three new characteristics shown by these synthetic diamonds

(1) There are occasional cubic faces on the synthetic diamonds which have a highly perfect smooth optical finish Fig 1 (× 480) shows such a cubic face photographed with the sensitive phase-contrast microscope It should be mentioned that this microscope has successfully revealed steps on other crystals which we have established interferometrically to be as small as some 2 5 A It follows, therefore, that the relative uniformity of the phase-contrast picture is evidence of an exceptionally smooth flat perfection of surface, a perfection locally approaching uniformity of the order of lattice dimensions Such smooth perfection on cubic faces is quite unknown on natural diamonds, although we have found such perfection occasionally on one or two highly perfect natural octahedral faces

(2) Quite a number of synthetic diamonds reveal a new form modification They are typical dendrites These dendrite characters we find in two distinct ways On most diamonds they appear as network (dendritic ?) overgrowths (see Fig 2, × 480) Slip effects are also clearly visible We believe the dendritic markings to be diamond since both strong heat and chemical reagents do not affect them However, far more striking is the occasional occurrence of complete dendritic crystals, typical examples of which are shown in Fig 3 (× 75)

In connexion with these dendrites attention is directed to the fact that they most closely resemble in shape some germanium dendritic crystals in our possession, and, of course, it will be recalled that the germanium crystal has the diamond structure

So far as we know, completely dendritic crystals such as we find here in synthetic diamond have never been reported for natural diamond, so that we have a second distinction between the synthetic and the natural crystals

(3) Our most notable observation has been the discovery of several spiral growths on quite a number of the good-quality cubic faces of the synthetics Fig 4 (× 480) shows our finest example, taken with the phase-contrast microscope On the original it can be clearly seen that the spiral arms are kinked, but that the separate components of the kinked arms are rectangular, the units are parallel to the edge between cubic and octahedral faces This establishes that the spiral really does belong to the diamond, for if it were a foreign overgrowth it would be too remote a possibility to find something completely epitaxial in lattice to fit the cubic face of the diamond In any event we cannot remove the spiral and are quite satisfied that it is really diamond

From our familiarity with comparison of our phase-contrast pictures with our multiple-beam interferograms on other crystals we can make a reasonably confident estimate of the step height of the spiral We estimate this to be of the order of some 100 A The quality of the surface between the spirals is very good, and on our originals we see close evidence of a secondary much weaker spiral originating from the same dislocation region

The kinking of the spirals is reminiscent of those we have seen at times on organic crystals and bears no resemblance to the silicon carbide spirals so often recorded in our laboratory Their character is essentially cubic The setting on our phase-contrast instrument tells us that these are true hillock spirals, the centre being the high region, as is to be expected

A number of spirals have been found on different crystals, and it would appear that most of them favour originating near a corner of the cubic face Fig 5 (× 650) is one such corner spiral and Fig 6 (× 650) is another Fig 6 exhibits a further interesting topographical characteristic, in that there are quite clearly shown a number of distinct slip lines crossing the spiral arms

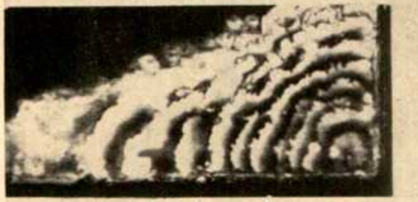
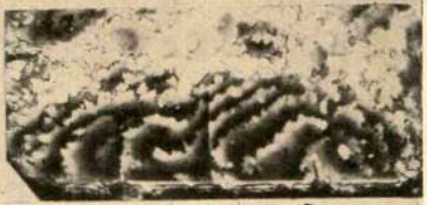
4.(X480)



5.(X650)



6.(X650)

Two matters appear to call for comment. The first is that these micro-crystals were grown rapidly, which is probably far from the case of the natural diamonds. A second, and perhaps more important, point is that, according to Dame Kathleen Lonsdale, this type of synthetic diamond may have up to even 3 per cent impurity included, in the form of metal carbide. It may well be that the inclusion of so much metal carbide in the lattice is responsible both for the appearance of the dendritic form and also for the appearance of the spiral dislocation, since neither of these features appears in the natural diamond.

Having made these observations, we secured for examination, through the courtesy of Mr. R. G. Mason, of Industrial Distributors (London), Ltd., no less than fifty well-formed natural cubic diamonds. All were Congo boarts, and the idea behind this was that we wished to examine natural cubes which clearly contained impurity too. The colours were greys, browns and blacks. Many of the 300 faces available are hopelessly too rough for precision optical examination, but some of the smaller stones were of reasonable surface quality. We have found no trace either of (*a*) a high-quality surface or (*b*) spirals.

Thus we still confirm the complete absence of any growth spirals on natural diamond faces, whether octahedral, dodecahedral or cubic. We therefore incline strongly to the view that both the spirals and dendrites reported here are due to some special causes distinguishing the synthetic from the natural diamond. This may be either due to different conditions during formation, or alternatively it may be due to metal carbide inclusion.

A VIVIPAROUS DEEP-SEA JELLYFISH

By DR. F. S. RUSSELL, C.B.E., F.R.S.
Marine Biological Association, Plymouth

ON a cruise off Santander, to collect deep-sea animals for Dr. S. K. Kon and Dr. L. R. Fisher, of the Development Commission Fisheries Research Biochemical Unit, R.V. *Sarsia* brought up on October 18, 1959, in a deep haul with the Isaacs Kidd pelagic net (3,300 metres of wire out) a very remarkable jellyfish (Fig. 1).

This is a deep brownish-red and plum-coloured semaeostome scyphomedusa measuring about 50 cm. across the umbrella. It has four simple mouth arms each more than 1 metre in length. It apparently has no tentacles. The stomach is about 25 cm. in diameter and from it issue 17 or 18 straight radial canals alternating with a number of canals joined to form networks and running for 6–7 cm. towards the umbrella margin, after which they all break up peripherally into a much finer anastomosing network. The margin is somewhat damaged but there are indications of a continuous ring canal. There are four inter-radial gonadial pores each 1·5 cm. in diameter.

But the most remarkable feature is that the medusa is viviparous. Each of the four gonads

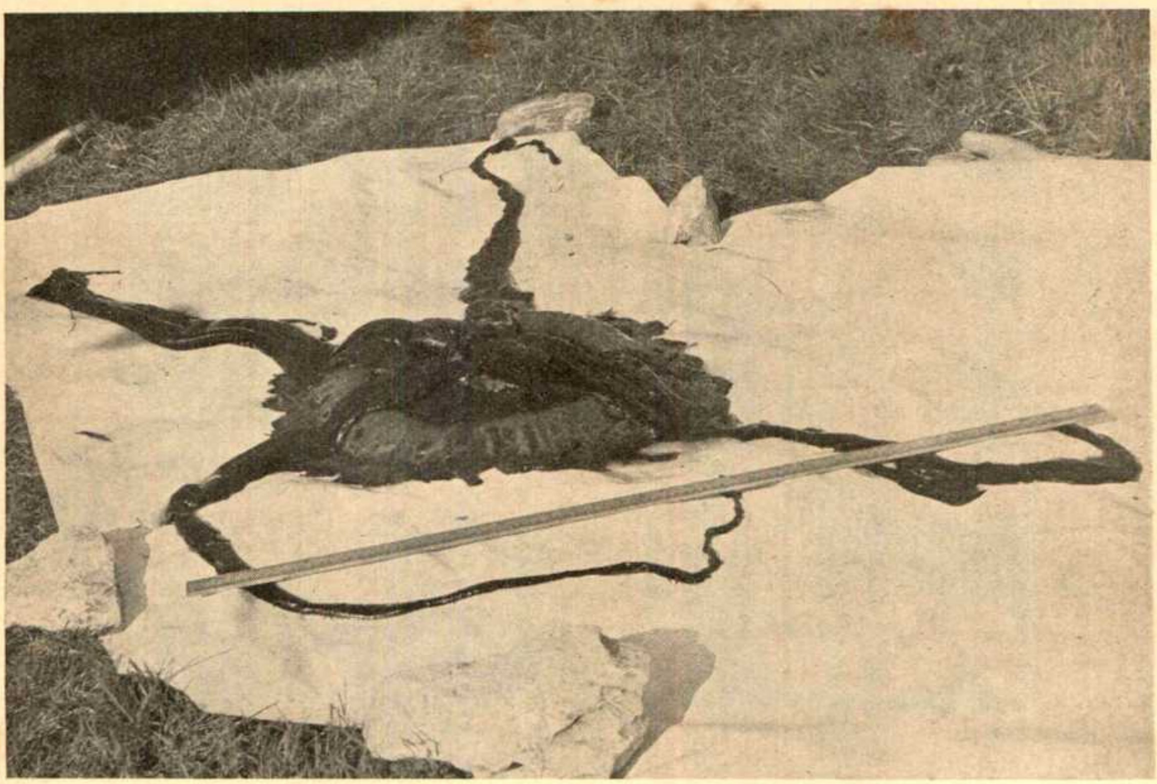


Fig. 1. *Stygiomedusa fabulosa* n.g., n.sp. There is a metre rule in the foreground

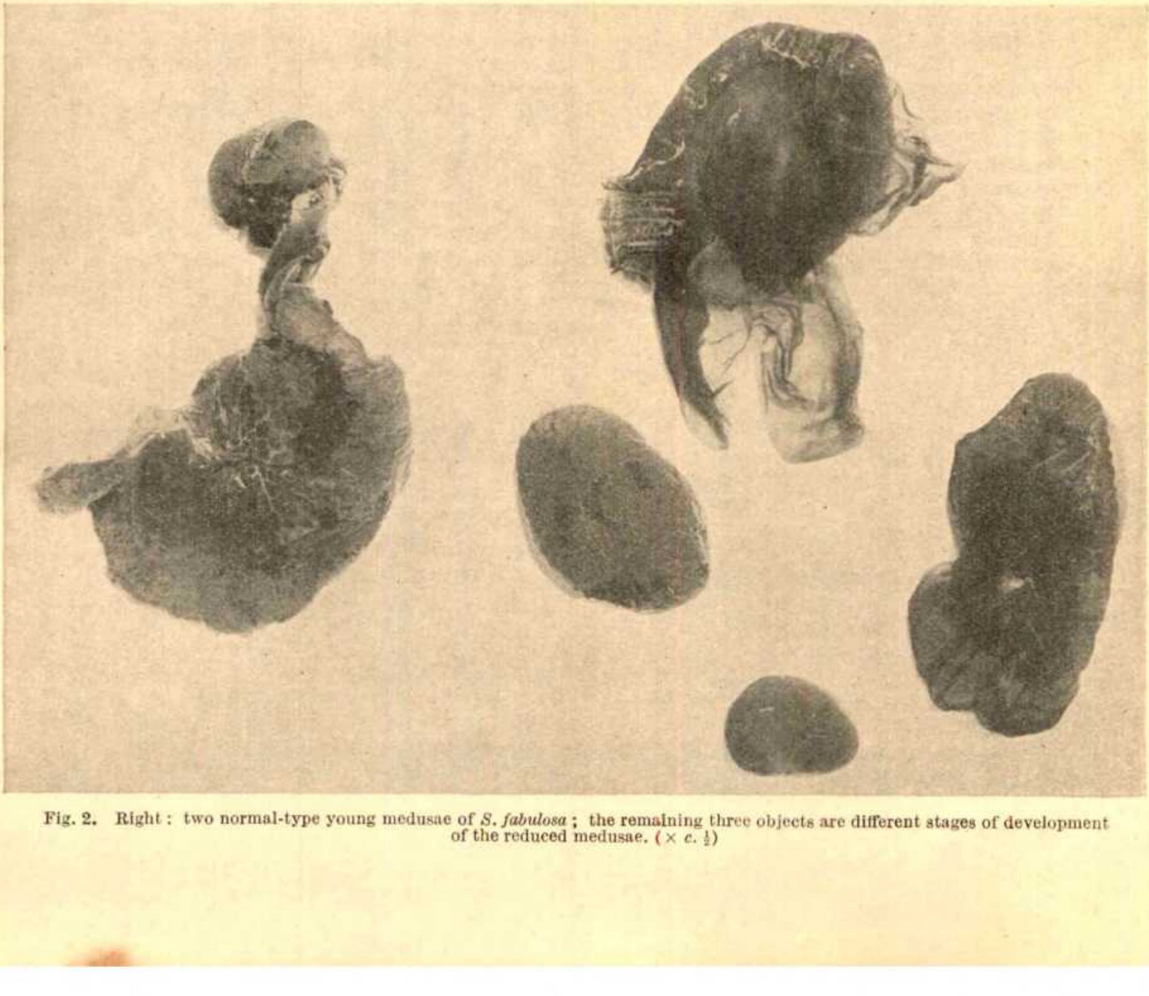

Fig. 2. Right: two normal-type young medusae of *S. fabulosa*; the remaining three objects are different stages of development of the reduced medusae. (× *c*. ½)

bears several white ovoid bodies attached to its wall These are elongated and narrowing sharply distally, and they vary in size from 1 0 cm × 0 5 cm to 5 0 cm × 2 5 cm One still larger, 7 5 cm × 5 0 cm, contains a large developing medusa There are two fully developed young, each about 10 cm in diameter These are perfect except that each has a large hole in the apex of the umbrella, presumably where they were, perhaps prematurely, separated from the stalk They have 20 or 21 marginal sense organs and about sixty marginal lappets Neither has any tentacles and this confirms their absence in the adult The mouth arms are well developed and broad and filamentous The developing gonads are already fully visible There are many canals issuing from the stomach, all forming a very branched network of canals around the periphery as in the adult This network runs into a continuous ring canal round the margin

There are also four objects which I thought at first to be developing young broken away from their stalk Two of these appear as rather featureless lumps of jelly with a honeycombed pattern In one there is the obvious beginning of the development of a lobed umbrella margin and there is one which has developed into a flat disk-like object about 10 mm in diameter (Fig 2, left) This is evidently a reduced medusa, because it has ten marginal sense organs, but no mouth The nature of these bodies must await further examination

There is no doubt that this is an entirely new semaeostome scyphomedusa coming near the Ulmaridae but differing in the absence of tentacles I am naming it *Stygiomedusa fabulosa* n g , n sp , and I hope later to be able to give a more detailed description

The position of capture was approximately lat 44° N , long 3° 45′ W It cannot be said from what depth the specimen actually came, but from its coloration and its habit of viviparity it must certainly normally live at great depths

I would like to thank Capt C A Hoodless and all those on board R V *Sarsia* for the care they took in preserving this specimen and bringing it back safely to the laboratory, and Mrs E A Peace for taking the photographs

CONSERVATION IN THE SCOTTISH HIGHLANDS

A SYMPOSIUM on "Conservation in the Scottish Highlands" was held by the Scottish Branch of the Institute of Biology during September 29 and 30 in Glasgow, followed on October 1 by an excursion to the Black Wood and Moor of Rannoch The following papers were read "Problems of Conservation in the Highlands", by Prof W H Pearsall (Nature Conservancy), "Geology of the Scottish Highlands and Islands", by A C MacGregor (Geological Survey of Great Britain, Edinburgh), "Soil Conditions in the Highland Areas", by R Glentworth (Macaulay Institute for Soil Research, Aberdeen), "Soil Erosion in Scotland", by R M Gorrie (ex-Indian Forest Service, Edinburgh), "The Role of Bracken in Highland Ecology", by Prof K W Braid (Aberdeen), "Scottish Soils in Relation to Afforestation", by W O Binns (Macaulay Institute for Soil Research), "Peat Afforestation", by M V Edwards (Forestry Commission), "The Effect of Conservation Practices on Animal Distribution", by W J Eggeling (Nature Conservancy), and "Conservation of Sheep Grazing", by R F Hunter (Hill Farming Research Organization) The present article is based on these papers and on the discussions which followed them, and the views expressed are not necessarily those of the reviewer

The Scottish Highlands comprise, in a geological sense, that part of the country to the north and west of the Highland Boundary Fault This area, in addition to the traditional crofting counties, includes more prosperous farming counties such as Aberdeenshire, Moray, Nairnshire, Banffshire and parts of Perthshire It is in the crofting counties that the problems of depopulation, social decay and land degradation have reached serious proportions, and it is these that are causing concern

When considering the Highlands, and conservation there, it is important first to pose the question, what are we trying to conserve ? It must be realized that this is a devastated habitat if the human and domestic animal populations are considered, the ratio one to the other, and the density, in the poorest parts of the Highlands, are of the same order as in parts of Africa where the country is described as semi-desert

All the evidence shows that the Highlands were once much more fertile than they are to-day Remains of large trees are found in desolate peat bogs, hillsides now bare and scree-covered show a brown forest soil below the accumulated debris of erosion, remains of human habitations are found associated with the remains of very large red deer at elevations of more than 2,000 ft , where now there is only cotton grass, heather and *Nardus*

The blame for the present desolation that characterizes much of the Highlands has often been laid on a deteriorating climate, and while it seems fairly certain that the climate has got worse in the past 2,000 years—wetter and colder—this period coincides with man's first large-scale impact on Highland biological systems the two cannot therefore be separated, but wherever deterioration has occurred, man has been present It is therefore important to get an idea what the country was like before man interfered, if any conclusions about land-use reached are to be correct

The Highland vegetation about 2,500 years ago consisted mainly of forest, grading into shrubby heath at 2,000–3,000 ft , which merged into arctic alpine vegetation where the hills were high enough Tension zones would have existed between these vegetation types, and in the deteriorating climate both blanket and raised bog tended to form extensively, and these gradually killed out much forest on the higher slopes Felling and grazing would mean retreating forests on the lower slopes Work in another mountainous area, the English Lake District, has shown that if the nitrogen content of lake deposits is taken as a measure of soil fertility at the time of deposition, and the flora of that time assessed from pollen remains, then fertility fell at the same time as the forests were cleared.

Though the natural biological system has been evolved over millennia, and is best adapted to the environment, it is not practicable to re-afforest all the land that has been cleared in the past two thousand years, and a compromise must be reached.

The failure of the 1745 rising and the break up of the clan system, with the introduction of sheep to the Highlands on a large scale for the first time, resulted in rapid devastation of the forests, already depleted by earlier fellings, and the slow death of large forest areas due to the prevention of natural regeneration by grazing. Sheep have thus been abundant in the Highlands for only 200 years, and though compilation of an accurate record of sheep populations presents great difficulties, it does seem that while numbers in the Highlands have declined in the past ninety years, in the Southern Uplands they have remained steady. This decline is probably due in part to too great a drain being made on the meagre natural resources of the Highland areas: the rocks are in general metamorphic formations poor in nutrients, with more fertile sedimentary deposits only occurring in quantity in Orkney, Caithness and the Moray Firth area. Agriculture in these areas must therefore be at a lower level of productivity than in areas more favoured geologically and climatically. Recent work by the Hill Farming Research Organization has shown that one reason for the gradual decline in the fertility of sheep runs is the feeding and manuring pattern, which causes a redistribution of nutrients from one vegetation type to another; in addition there are the normal losses due to leaching and marketing sheep, which must be made good artificially. The high ratio of sheep to cattle has been cited as a cause of degradation, and as the presence of cattle helps to put right the damage due to differential manuring, the two animals are truly complementary; any relative increase in the numbers of cattle is therefore beneficial.

The problem of spread of bracken is important in the Highlands, and though clearance is expensive there appears to be little doubt that with modern methods much quite good land could be cleared economically.

A great increase in the land area under forest in the Highlands has already been achieved by private owners as well as by the Forestry Commission, and the Commission now has authority for 'social planting' in areas where it would normally be uneconomic. The soil types available for Highland afforestation are peaty podzols with iron pan, peaty gleys, iron podzols, brown forest soils and deep peat. Peaty podzols and deep peat are two difficult types available in large amounts, and on both these the problems of establishment have been solved, now that suitable ploughing equipment has been developed and the need for additional phosphate realized; additional potash will probably be required on many peat soils. Pole-stage crops at least can be raised on deep peat dominated by *Trichophorum*, and unless windthrow proves serious, plantations should be successful in many Highland areas hitherto considered unplantable. It must be remembered, however, that blanket bog is the climatic climax in many areas.

Erosion has often resulted from deforestation, long-term overgrazing and bad draining and ploughing practices; these causes of erosion can be eliminated, though much damage has already been done. If in the relatively equable climate of Scotland erosion never takes place on a tropical scale, sheet erosion still accounts for an enormous loss of top soil, though this is seldom admitted by farmers. The practice of repeated burning, especially on peaty soils, results in degradation of the flora and eventual erosion.

A number of interests and organizations are concerned with the Highlands—forestry, crofting, sheep and cattle farming, the Hydroelectric Board, fishing, shooting, and not least tourism. At present, these interests tend to go their own ways. Rural development surveys of a number of Highland areas covering more than 3,000,000 acres have recently been made by the Department of Agriculture, and in consultation with the Forestry Commission they are deciding the best division of land for each naturally demarcated area; however, there is no guarantee that owners and crofters will co-operate in these schemes.

The future of the Highlands is bound up with the future of crofting. Whether, in this age of mechanized agriculture, crofting as it is at present practised can survive is still doubtful. Unfortunately, such a haze of emotion overlies and obscures the whole subject that it is very difficult to obtain an objective view. Although where the Forestry Commission has been working on any scale the drift to the towns has been stopped, crofters are not always willing to work for the Commission, and labour may have to be brought into areas where unemployment relief was the original objective.

The integration of farming and forestry is a prerequisite of proper land use. There are, however, conflicting claims, for if lower and middle slopes of glens are planted with trees, the ratio of inbye to hill land —usually about 6.94 per cent, which is already too low—will be still further lowered. A possible solution is to use red deer as grazing animals for the high tops, treating them as a natural resource. The population of red deer is admitted to be higher than the land can reasonably carry, and as it is undesirable to re-introduce the carnivores which are the natural predators, man must control their numbers. For example, the Nature Conservancy has calculated that the herd of red deer on Rhum should be reduced by a half to two-thirds, and the same is probably true for most parts of the Highlands.

A comparison with other regions may show what is needed. In Sweden, agriculture is subsidized by forestry, and English and Lowland agriculture is effectively subsidized by industry, while in the Highlands, some of the natural resources, for example electric power and water, are exported with little or no return: the Hydroelectric Board benefits from afforestation by a reduction of the rate of silting in reservoirs, and water boards benefit from an evening-out of run-off.

Work by the Nature Conservancy, Forestry Commission Research Branch, and Hill Farming Research Organization, to mention only three bodies, is filling in many gaps in our knowledge of Highland biological systems, but the general impression the reviewer gained from this stimulating symposium was the need for more basic information, and for a more vigorous, integrated, approach to the Highland problem by all concerned.

W. O. BINNS

OBITUARY

Prof. G. O. Sherrard

With the death in September last of Prof. G. O. Sherrard, affectionately known to all as 'G. O.', horticulture in general and Irish horticulture in particular has lost a most distinguished devoted scholar. He was born seventy-six years ago on the family estate near Cork City. As a boy, he had two great ambitions, to become a gardener and to teach. His father appeared to have different ideas and sent him to Westward Ho, Old United Services College and later to Woolwich Military Academy, where he received his commission.

A wish to travel prompted Sherrard to volunteer for foreign service. He was sent to Gibraltar, where he contracted Malta fever. Home on sick leave and advised to adopt an outdoor life, he naturally and fortunately chose horticulture. The soldier turned gardener now trained at Albert College, and afterwards entered the Royal College of Science, Dublin, on a scholarship, where in 1910 he obtained the A.R.C.Sc.I.

After a short period as a teacher of rural science in Co. Kildare, he was awarded a scholarship by the Development Commissioners and went to the John Innes Horticultural Institution to study genetics and plant breeding under Prof. W. Bateson. He interrupted study for active service in the First World War, reached captain's rank and was awarded the Military Cross.

From war to study again, and then back to Ireland as lecturer in horticulture in the Royal College of Science. At the foundation of the Faculty of Agriculture in 1926 he transferred to University College, Dublin, where in 1940 he became professor of horticulture—Ireland's first horticultural professor.

The Royal Horticultural Society of Ireland awarded him its Gold Medal for conspicuous service to Irish horticulture in 1941, and in 1953 the Horticultural Education Association elected him as president, the first and only Irishman to be so honoured. He was an active member of the council of the Royal Horticultural Society of Ireland and was president of that Society during 1955–58.

Prof. Sherrard was a wonderful teacher and a fine research worker, who contributed nobly to Irish prosperity. In his life-time, he witnessed a complete change in the horticultural pattern—a transition from the big estate garden to that of the suburban villa, and the remarkable development of commercial horticulture within the past quarter of a century. Quick to perceive the change, and adequate to cope with the changing requirements, he provided trained personnel for advisory, research and administrative posts. He was an inspiration and guide at a very critical period.

Although Sherrard's name as a research worker tends to be linked almost exclusively with his wonderful pioneering work on Brussels sprouts, he found time during a very busy life to publish papers dealing with the nutritional, breeding and cropping aspects of vegetables, fruits and glasshouse crops. He gave many public lectures, wrote a book on fruit and vegetable growing, contributed weekly press articles on popular gardening, and through friendly informative weekly gardening talks from Radio Eireann became the doyen of Irish broadcasting.

His outstanding work has been concerned with the breeding and improvement of commercial strains of Brussels sprouts, on which he embarked in 1924. Out of the chaos of that time he created a high order, and as monuments to his skill, patience and abiding interest he has left behind such wonderful varieties as Glasnevin Supreme, Irish Elegance and the freezer Irish Glacier. In whatever clime this crop is grown, Sherrard's name will be remembered and honoured.

Modesty and simplicity were innate characteristics of the man who put Glasnevin and Ireland before self-exaltation. An octogenarian, thinking aloud at his graveside, summed up what all of us who knew him felt in our hearts—"he was a great man and a thorough gentleman". We are the poorer for his passing, but take heart from his fine example.

NEWS and VIEWS

General Post Office: Engineering Appointments

The Postmaster General has approved the appointment of Mr. A. H. Mumford, deputy engineer-in-chief, to be engineer-in-chief in succession to Sir Lionel H. Harris, who is retiring on January 31. Capt. C. F. Booth and Mr. D. A. Barron, both of whom are assistant engineers-in-chief, have been appointed deputy engineers-in-chief.

Sir Lionel Harris, K.B.E.

Sir Lionel Harris joined the Post Office Research Branch at Dollis Hill in 1922, having spent four years with Signals in the Australian Imperial Forces and graduated in the University of London from the City and Guilds Engineering College. He was superintending engineer of the North Midland District of the Post Office on the outbreak of war in 1939, when he left to join his Territorial Army unit. After Dunkirk he successively commanded G.H.Q. Signals, was chief signal officer, Lines of Communication, and finally for two years chief of General Eisenhower's Telecommunications Section. After the War he became for four years director of the Post Office in Scotland, then controller of research and finally (in October 1954) engineer-in-chief.

Mr. A. H. Mumford, O.B.E.

Mr. A. H. Mumford was born in London in 1903 and was educated at Bancroft's School and the University of London. He entered the Post Office in 1924 as an assistant engineer; before very long he joined the Dollis Hill Research Laboratory, where he was particularly concerned with short- and ultra-short-wave radio systems and with multi-channel telephony and television transmission over coaxial cables He was involved in the development of the first trans-Atlantic radio-telephone service, visiting the United States in connexion with this in 1927 He was also closely connected with work on the remote-controlled short-wave radio transmitters when the Post Office Rugby Radio Station extension was being designed He was in charge of the Post Office Radio Branch during much of the war period He became deputy engineer-in-chief of the Post Office in 1954 Mr Mumford has been a vice-president of the Institution of Electrical Engineers since 1958

Capt C. F Booth, O B.E.

CAPT C F BOOTH started in the Post Office in 1923 and was for twenty-five years in the Radio Branch Laboratories of the Post Office Research Station at Dollis Hill He is an international expert on quartz-crystal and primary-frequency standards and is part author of a comprehensive text-book on the subject "Quartz Vibrators and their Applications" He is at present leading the United Kingdom delegation to the International Telecommunications Union Radio Conference in Geneva In 1952, Capt Booth was appointed deputy director of the newly established External Telecommunications Union He returned to the Engineering Department as assistant engineer-in-chief of the Post Office in 1954

Mr. D A Barron

MR D A BARRON was born in Bristol in 1907 and was educated at Bristol Grammar School and the University of Bristol He entered the Post Office Engineering Department as a probationary assistant engineer in 1927 and gained his early experience in the Technical Section of the former South Western Engineering District at Bristol and in Plymouth He was transferred to the Telephone Branch of the Engineer-in-Chief's Office in 1940 as assistant staff engineer In 1945, he led a team which went to India to prepare plans for the transfer of the Calcutta telephone service to automatic working On his return to Britain in 1947 he was placed in charge of a working party which examined the problems of subscriber trunk dialling which was introduced in Bristol a year ago He was appointed assistant engineer-in-chief in 1954

Animal Research at the Commonwealth Scientific and Industrial Research Organization

Mr D A Gill

MR D A GILL, chief of the Commonwealth Scientific and Industrial Research Organization Division of Animal Health and Production, has retired after a lifetime of service to the animal industry A graduate of the Royal College of Veterinary Surgeons, London, he joined the Organization in 1934, succeeding the late Sir Ian Clunies Ross as officer-in-charge of the McMaster Animal Health Laboratory in the grounds of the University of Sydney He took a leading part in the practical development of methods for the control of blow-fly strike in sheep He has been influential in improving facilities for research for the sheep industry and was closely associated with the establishment of the Organization's laboratories at Prospect and Armidale, New South Wales, and Yeerongpilly, Queensland For some years Mr Gill lectured on veterinary bacteriology at the University of Sydney During the Second World War he was seconded for a time as pastoral adviser to the Department of War Organization of Industry Instead of appointing a successor to Mr Gill the executive of the Commonwealth Scientific and Industrial Research Organization has decided to split the large division (which has an annual budget of £850,000) into three divisions, namely, the Division of Animal Genetics, the Division of Animal Health and the Division of Animal Physiology

Dr J M Rendel

THE new chief of the Division of Animal Genetics will be Dr J M Rendel, of Sydney Dr Rendel went to Australia in 1951 from the Institute of Animal Genetics in Edinburgh As assistant chief of the Division of Animal Health and Production he has taken part in much of the Organization's animal breeding work, and has been particularly interested in cattle In 1958 he made a report on the cattle industry in Papua and New Guinea for the Department of Territories

Dr T S. Gregory

DR T S GREGORY, of Melbourne, has been appointed chief of the Division of Animal Health, with Dr D F Stewart, of Sydney, as associate chief Dr Gregory has been on the Organization's staff since 1926, except for a period of eight years as lecturer in bacteriology at the University of Melbourne, and during the Second World War

Dr. I. W McDonald

THE Division of Animal Physiology will be led by Dr I W McDonald of Sydney Dr McDonald gained a Hawkesbury diploma in agriculture before undertaking his course in veterinary science at the University of Sydney Before being appointed officer-in-charge of the Organization's Sheep Biology Laboratory at Prospect in 1955, he had spent several years at the Institute of Animal Physiology in Cambridge, England

Underground Test Explosions in Britain

THE Prime Minister said in the House of Commons on July 30 that H M Government has decided that tests involving small underground firings of conventional explosives should be carried out in the United Kingdom to obtain information on the detectability of small underground nuclear explosions He emphasized that no radioactive materials would be used The United Kingdom Atomic Energy Authority more recently announced that preparations were in hand for the first series of tests to be carried out towards the end of this year in a disused mineshaft in the Kit Hill area, north of Callington, Cornwall The Atomic Energy Authority, in consultation with the Atomic Energy Division of the Geological Survey, has now located a suitable site for a further series of tests at the Greenside lead mine, Glenridding, Westmorland This mine was about to be closed The owners of the mine are co-operating in the arrangements and have agreed to carry out the civil engineering work involved in preparing the underground chambers in the mine for the tests Preparations at the mine will begin shortly, and it is planned to carry out the tests in a few weeks time The potential productive capacity of the mine will not be impaired by the tests. The proposed series of tests will investigate the effects of firing charges at greater depths, and of greater size than is possible in the Kit Hill mine. Precautions will be taken to ensure that there will be no surface disturbance or damage. It is planned to register the results on seismic instruments at various distances from the mine. Local authorities and other interests concerned are being consulted and planning permission is being sought.

British Neutron Source Thermal Reactor

THE United Kingdom Atomic Energy Authority has signed a contract with the Hawker Siddeley Nuclear Power Co. for the purchase of a reactor to be installed at the Atomic Energy Establishment, Winfrith, Dorset, to be in operation by December 1960. Contracts for shielding, and other equipment associated with the reactor, are being placed. The reactor, which will be known as *Nestor* (Neutron Source Thermal Reactor), is based upon the Company's *Jason* reactor. Its purpose will be to provide the neutrons required for the experimental assemblies of nuclear fuels and moderators which are used to obtain data for the design of future reactor systems. To meet the requirements of the Authority, the *Jason* reactor has been modified to be capable of continuous operation at a power of up to 10 kW. and its layout has been altered so that it can drive up to five experimental assemblies simultaneously. Details of the modifications have been worked out in collaboration between the Authority and the Company. The nuclear fuel in *Nestor* is an alloy of highly enriched uranium and aluminium arranged in an annulus. Natural water is used both as coolant and moderator. The reactor is capable of operation of 10 kW. giving a thermal neutron flux of 10^{11} neutrons per cm.^{2} per sec. in the centre of the core and of up to 10^8 neutrons per cm.^{2} per sec. in typical assemblies. The thermal neutron flux can be varied by altering the reactor power-level, by using neutron shutters or by arranging the fuel loading in the annular core.

Dungeness and the Nature Conservancy

IN the light of the Government's recent decision to consent to the construction of a large nuclear power station on Dungeness, the Nature Conservancy states that the direct and indirect repercussions of the power station on the remaining area show conclusively that the future scientific interest will be too much reduced to qualify it for the status of a national nature reserve. The proposed Dungeness National Nature Reserve is accordingly abandoned and the negotiations for it will not be pursued. The Conservancy will not, however, cease to concern itself with the preservation of such assets as can still be saved. For this purpose the undeveloped area (apart from that section now compulsorily purchased by the Central Electricity Generating Board) will remain designated by the Nature Conservancy under Section 23 of the National Parks and Access to the Countryside Act, 1949, as a 'site of special scientific interest', and the Conservancy will accordingly continue to be consulted about any further development which may be proposed for any other parts of the area. The Conservancy will in particular welcome and encourage any measures which the Royal Society for the Protection of Birds may be able to take for maintaining and defending the fauna and flora and, in particular, the bird-life of the 1,234 acres of shingle which it owns between the power station site, the Lydd Army Ranges and the bungalow settlement. If Kent naturalists wish to attempt further salvage work in the remaining area of the 'site of special scientific interest' they will have the Conservancy's support. The Conservancy will continue to keep in touch with the Central Electricity Generating Board and its contractors with the view of minimizing destruction of scientific interest over the area surrounding the power station site.

Field Studies

ANNUAL reports of the Field Studies Council have recorded accounts of scientific investigations which have been made in areas surrounding the Council's field centres in Pembrokeshire, Suffolk, Surrey, Yorkshire, Salop and Devon. The growth of these centres and the increasing amount of original work which is being carried out at them have made it impossible to publish anything but a small part of the material available. The Council has now decided to issue an additional publication about new knowledge being gained in field-studies connected with archæology, botany, geography, geology and zoology. "Field Studies" will appear once yearly and, in time, it is hoped that the series of papers published for each centre will have grown into a thorough local survey. The first issue ("Field Studies", Vol. 1, No. 1 (May 1959). Copies obtainable from the Publicity Secretary, Field Studies Council, Ravensmead, Keston, Kent. 5*s*.) describes the birds, land-use, farm practice, and climate of parts of the Dale peninsula, the land snails of Flatford, the geomorphology of the Tillingbourne, stratigraphy and pollen analysis of Malham Tarn and Tarn Moss, the geography of the Alberbury Breccia, and freshwater studies in the Shropshire Union Canal.

The Young Darwin

To mark the hundredth anniversary of the publication of Darwin's "Origin of Species", a commemorative oration was delivered by Prof. C. F. A. Pantin at Christ's College, Cambridge, on September 29 ("Young Darwin and the 'Origin of Species'." By Dr. C. F. A. Pantin. Pp. 17. Cambridge: Christ's College, 1959). The address was noteworthy for a number of features. Attention was concentrated not on an old man suffering from ill health but on the pleasant, virile young man who went up to Christ's College in 1828 to prepare himself for the Church, the reasons for Darwin's subsequent ill health were also examined by Prof. Pantin, who suggested that this may have been due not to any suppressed psychological antagonisms towards his father, but to the hardships and rigours encountered during the five-year voyage on H.M.S. *Beagle*, a 10-gun brig of only 242 tons. Darwin's contributions to knowledge in many branches of natural history include references to the origins of coral seas. There are also some valuable gleanings of the way in which "The Origin of Species" emerged.

The London Mathematical Society

THE annual general meeting of the London Mathematical Society was held on November 19 at Burlington House. The De Morgan Medal was presented to Sir William Hodge, physical secretary of the Royal Society and Master of Pembroke College, Cambridge. In presenting the Medal, the president (Prof. H.

Davenport) paid tribute to Sir William's distinguished work in algebraic and differential geometry Prof Davenport briefly reviewed the Society's affairs, and announced that a loan granted by the Nuffield Foundation had enabled the Society to begin reprinting those of its publications which are out of print He also announced that the Oxford University Press had agreed to publish the Collected Papers of G H Hardy, with the assistance of an editorial board appointed by the Society Prof H Heilbronn (University of Bristol) was elected president for the ensuing session The retiring president delivered his presidential address on "Some Recent Progress in the Analytic Theory of Numbers"

Model Marine Engines

LIVERPOOL Public Museums have recently placed on exhibition a series of working models of steam reciprocating marine engines They cover the period 1837–1937 and start with the side-lever paddle engine of 1837 Then comes a set of oscillating cylinder paddle engines of the 1840's Also in the paddle engines section is a set of diagonal compound machinery of about 1890 Screw propulsion came into general use during the 1840's and '50's, and the earliest model is of the horizontal return connecting-rod type All the remaining screw engines are inverted direct-acting The models are displayed working, and the side-lever and oscillating cylinder engines run at ten and twelve revolutions a minute, which is their correct working speed The other models run at forty revolutions a minute, which is well below the average speed of their real prototypes Running at this low speed is necessary, however, to preserve the bearings of the models, for they have been acquired for posterity as well as the present generation The models are fully described in a paper by Mr E W Paget-Tomlinson in the October issue of the *Museums Journal*

Replicas of Workshops

THE *Museums Journal* of September includes an account by Mr Keith Dunham of the workshops which have been reconstructed in the Museum of Science and Industry at Birmingham The city has always had a reputation for a multiplicity of trades, all of which have grown from the skill in iron-working possessed by the inhabitants since early times The building erected in the mid-nineteenth century in which this Museum is now housed was formerly the premises of a firm of silversmiths and electroplaters, and thus gives an excellent background for reconstruction of early workshops The trades chosen were those of the brass-turner, the action filer (gunmaker), the nailer, the jeweller and the cooper The workshops of a silversmith and brass-founder were already in existence Details of the display are given in the paper quoted

Phycology in Britain

THE recent issue of the *British Phycological Bulletin* (No 7, July 1959) contains the presidential address, "Buoyancy in Relation to the Ecology of the Fresh-water Phytoplankton", presented to the Society by Dr J W G Lund, together with abstracts of the other papers read at the London meeting in January 1959 There are also the first part of a list of the chromosome numbers in the Chlorophyta, notes on the algal herbaria of Hudson and Lightfoot, a list of marine algae collected in the course of field excursions organized during the Third International Seaweed Symposium held in Galway in July 1958, reviews of recent phycological literature and a number of shorter articles

Prize for Man-powered Aircraft Flight

THE Royal Aeronautical Society announces that a prize of £5,000 has been offered by Mr Henry Kremer for the first successful flight of a man-powered aircraft, designed, built and flown within the British Commonwealth under conditions to be laid down by the Royal Aeronautical Society The Royal Aero Club is to be invited to act as official observers The prize is offered personally by Mr Kremer and not by any of the companies with which he is associated Mr Kremer has been on the production side of industry all his life, and before the War pioneered the resin-bonded composition board industry After the War he began to take an interest in plastics, and in 1950 he formed Microcell, Ltd , which has been extended to include an aircraft engineering division and an electronics division, as well as the plastics division Since 1950 two other companies have expanded under his chairmanship, namely, Glass Yarns and Deeside Fabrics, Ltd , producing glass fibre, and Artrite Resins, Ltd Microcell, Ltd , has since merged with BTR Industries

Postdoctoral Awards U S National Science Foundation

POSTDOCTORAL fellowships are offered by the U S National Science Foundation to citizens of the United States with special aptitude for advanced training and who hold the doctoral degree or have the equivalent in training or experience Fellowships will be awarded in the mathematical, physical, medical, biological, engineering and other science fields, including anthropology, psychology (other than clinical), geography, certain interdisciplinary fields and selected social science fields A grant of 4,500 dollars a year will be awarded to successful applicants under the postdoctoral fellowship programme Dependency allowances will be made to married Fellows Fellows may engage in study and/or research at appropriate non-profit American or non-profit foreign institutions A limited allowance to aid in defraying a Fellow's cost of travel will also be available Further information can be obtained from the Fellowship Office, National Academy of Sciences—National Research Council, 2101 Constitution Avenue, N W Washington 25, D C All applications must be made by December 22

"Animal Clocks"

REFERRING to the report of his paper at the York meeting of the British Association in the symposium on "Animal Clocks", published in *Nature* of September 12, p 763, Dr Malcolm B Wilkins states that the last two sentences should read as follows "The period of the rhythm is slightly sensitive to temperature Ball and Dyke have shown that the growth-rate rhythm in *Avena* coleoptiles is inhibited in nitrogen, and Bunning has shown that the period of the rhythm of leaf movement of *Phaseolus multiflorus* is increased by the mitotic poisons colchicine and phenylurethane "

University News · Leeds

THE following grants are announced £4,310 for the period of one year from the National Coal Board, Scientific Department, for six research projects in mining , £3,860 from the Central Electricity Generating Board for research on the utilization of pulverized fuel ash in the Department of Agriculture

Dr A F Thomas has been appointed lecturer in the Department of Organic Chemistry

London

The following appointments are announced Mr P R Bell, of University College, to the University readership in botany tenable at that College , Mr A V Bradshaw, of the Imperial College of Science and Technology, to the University readership in extraction metallurgy tenable at that College

The title of professor of electrical engineering in the University of London has been conferred on Dr A H M Arnold, in respect of his post at King's College

Oxford

Research grants are announced as follow from the Department of Scientific and Industrial Research a grant not exceeding £35,900 for the period July 1, 1959, to July 31, 1962, for research on high-energy phenomena using photographic plates, being carried out under the direction of D H Wilkinson, professor of experimental physics , from the United Kingdom Atomic Energy Authority a grant not exceeding £8,500 for the period October 1, 1959, to September 30, 1962, for a study of polarized nuclear systems using resonance techniques, to be carried out in the Clarendon Laboratory under the direction of Dr F N H Robinson , and from the Ministry of Aviation a grant not exceeding £1,395 for the year beginning October 1, 1959, for research on the mechanism of operation of the cryotron, being carried out in the Clarendon Laboratory under the direction of Dr K A G Mendelssohn, reader in physics

Sheffield

It is announced that the Strength of Materials Laboratory in the Department of Mechanical Engineering is to be named the F C Lea Laboratory, in honour of the late Prof F C Lea, who was professor of mechanical engineering during 1923–36 and whose researches carried out in Sheffield made important contributions to knowledge in this field

Announcements

Mr Bryan Harris, a graduate in metallurgy from the University of Birmingham, has been appointed to a Tube Investments Research Fellowship for work in the physics and chemistry of solids, at the Cavendish Laboratory, Cambridge

Mr G G Gouriet is to give the Christmas Holiday Lecture of the Institution of Electrical Engineers on December 30, at 3 p m , and repeat it at the same time on the following afternoon He will speak on "Colour Television" Tickets, which are free, must be obtained from the Secretary, Institution of Electrical Engineers, Savoy Place, London, W C 2

The Science Museum, South Kensington, London, S W 7, has arranged the following Christmas lectures for boys and girls December 22 and 23, "From Man Power to Atomic Power", by Mr Victor Wall , December 28 and 29, "From Tinfoil to Tape the History of the Gramophone", by Mr John Cain , December 30 and 31, "The Story of Flight", by Mr Victor Wall , January 1, "Science and Magic", by Mr John Cain

The Zoological Society of London has arranged the following Christmas Lectures for children December 29, "Looking for Animals in East Africa" by Mr E H Tong , December 31, "British Carnivores" by Mr R F S Creed , January 4, "Animals in Hiding" by Mr D G Lambert The lecture hour is 3 p m and admission is free by ticket obtainable on application to the Education Department, Zoological Society, Regent's Park, London, N W 1 , only three tickets can be supplied to a Fellow for each lecture

The seventh Sir Thomas Middleton Memorial Lecture will be given in the Auditorium, Wellcome Building, 183 Euston Road, London, N W 1, on December 8 by Dr E B Worthington (deputy director-general (scientific), Nature Conservancy), entitled "Nature and Agriculture" Further information can be obtained from Miss D F Bray, Sir Thomas Middleton Memorial Trust, 3 Dean's Yard, London, S W 1

A two-day symposium has been arranged by the Linnean Society during December 17–18, entitled "Quaternary Ecology" The meeting will be held at Burlington House, Piccadilly, W 1 Further information can be obtained from the General Secretary, Linnean Society of London, Burlington House, London, W 1

The British Society of Rheology will hold a meeting in Manchester during April 7–8, and will include sessions on lubrication, disperse systems, and the methods and concepts of rheology , and a choice of visits to British Rayon Research Association, the Shirley Institute, Jodrell Bank and the Fluid Motion Laboratory of the University of Manchester Full details can be obtained from the Hon Secretary of the Society, 8 The Broadway, Pontypool, Mon

The Electronics and Communications Section of the Institution of Electrical Engineers, in association with the International Federation for Medical Electronics, is organizing the third International Conference on Medical Electronics which will be held at Olympia, London, during July 21–27, 1960 Further information can be obtained from the Secretary, Institution of Electrical Engineers, Savoy Place, London, W C 2

Sunvic Controls, Ltd , is to combine with the Instrument and Meter, Scientific Apparatus and X-Ray Departments of Metropolitan-Vickers Electrical Co , Ltd , to form the Instrumentation Division of Associated Electrical Industries, Ltd

It is announced by Birlec, Ltd , that the name of the company is to be changed to A E I -Birlec, Ltd The change coincides with the final reorganization of the structure of the parent company, Associated Electrical Industries Ltd , into several product divisions The internal organization of Birlec, Ltd , will not be affected The company will continue to operate as in the past for the manufacture of heat-treatment furnaces, gas plants and adsorption dryers The name of its associate company, Birlec-Efco (Melting), Ltd , will not be changed

Errata In the communication entitled "Nature of the Olefines produced by Apples" in *Nature* of September 26, p 996 par 2, line 15, for "1-hexane" read "1-hexene" , par 3, line 4, for "necessary" read "unnecessary"

BRITISH IRON AND STEEL RESEARCH ASSOCIATION

LONDON GROUP LABORATORIES OPEN DAYS

THE British Iron and Steel Research Association recently held open days at its Battersea premises to show its members something of the current and continuing work of the London Group laboratories. Of the five Divisions and three Departments of the Association, the London Group comprises the Plant Engineering and Energy Division, part of the Iron-making Division, and the Physics, Chemistry and Operational Research Departments.

Notwithstanding the wide spread of interests represented, the displays clearly reflected the interest of the steel industry in automation and allied subjects. Not only has the Physics Department recently formed a new Section to deal specifically with the subject of automation, but also the Electrical Engineering Section of the Plant Engineering Division has pioneered several developments which, in effect, apply 'automation' in the handling of information.

Some years ago this Section developed a 'performance recorder' which recorded and stored production data, and processed it so that periodical tabulated totals would be available in printed form for office use. Equipment of this kind has since been installed in several British steel-works and other factories, and a development of the basic idea was designed and supplied for a big Russian contract for the erection and equipment of a giant tyre factory in the Soviet Union by a British consortium.

The Electrical Section of the Association has now completed a further development—the 'Tallimarker' system for conveying essential information in a steel-works. Starting from the premise that efficient production depends on accurate, easily accessible information, this automatic system represents a great advance on the traditional pattern of circulating data by paper chits or word of mouth. It consists basically of three essential units: 'push-button' desks, and display screens at key points along the production line, and a central 'memory'. As applied in a steel-works rolling mill, for example, the operators at the soaking pit, primary mill, primary shears, section mill and saw-bench, would all have press-button stations into which information is fed, and all stations after the soaking pit would have a display screen showing the previous history of the product as it is progressively reduced from the original ingot. As the ingot or subsequent bloom passes down the line, the operator at each point reads off the facts on his display screen, and feeds in more information as he completes his operation, for the following stations. When a section is being cut at the final saw, the 'Tallimarker' store holds the complete history of the section. Details are relayed to the mill office and recorded in the most convenient form; for example, on a teleprinter record, punched card or magnetic tape. The basic system can, of course, be adapted for use in any production line; in construction it is reliable, robust and accurate, reduces clerical work, and saves time and money.

The new Automation Section of the Physics Department is studying several possible applications of automation to steel-works production methods. Among these is a scheme for the automatic inspection and treatment of rolled billets, which often have surface defects which must be made good. The new plan is to dip the billet in a fluid which fluoresces under ultra-violet light, and which penetrates the flaws. The billet will then be washed and passed to an inspection chamber, where the flaws show up under ultra-violet lamps and can be detected by photocells. The photocells can be linked electrically with finishing tools such as grinders or de-seaming torches for automatic treatment. Billets without flaws would be diverted and stored, later rejoining the line in their original order.

The increasing use by manufacturers of steel sheet and strip has led to a growing pre-occupation with methods of quality control. Automatic gauge control was developed by the Association some years ago, and has been widely adopted in industry. On show at Battersea was a proposed new method of measuring small reductions in strip thickness, which can be integrated with automatic correcting equipment. The system is based on the fact that the reduced strip leaves the rollers faster than it enters them—the greater the reduction, the greater the change in speed. Therefore, by measuring the change in speed, the reduction can be calculated. It is proposed to do this by comparing identical signals obtained by photo-electric measurement of reflectivity at two points 'down the line'. The time-lag between the signals gives the time the sheet or strip takes to travel the distance between the points of measurement. One of these instruments before and one after rolling will give the change in speed, and therefore the reduction in thickness. This 'non-contact' method avoids any complications which would arise from the use of contact rollers or similar devices.

Because automatic control demands as an essential prerequisite exact information, instrumentation may be said to be the first step towards automation. An interesting new instrument is the 'bar section meter' displayed by the Physics Department. It has been designed to measure simultaneously four diameters of a hot solid bar at 45° intervals while it is moving at a high speed. This information is valuable not only for checking that the section is being rolled to the specified size, but also for early detection of such defects as finning.

The water-cooled viewing head forms images from the opposite edges of the bar across each diameter to be measured. These images are placed side by side in a single field of view, and are magnified and transposed so that the edges point towards each other. The instrument thus shows four parallel bands of light representing the four diameters measured. Each nominal diameter of the bar is set on the instrument by a micrometer adjustment; if this corresponds to the diameter being viewed, then the appropriate band is continuous across the field of view (that is, the fact that the edge images have been brought to coincidence in any band indicates that the diameter is as set) If there is a gap in the middle of the band, the diameter of the bar is less than the scale reading, while a bright central zone caused by the images overlapping indicates that the diameter is greater First experiments show that deviations in diameter of about 0 005 in can be detected

Leaving the theme of automation, an interesting sidelight on the technique of research was provided by the Ironmaking Division Although the blast furnace is a remarkably efficient vessel for the large-scale exercise in physical chemistry which iron-making represents, there is still much to be learned about the course of the reduction process There are severe limits on what can be deduced from experimental work on a blast furnace, and the Division therefore developed laboratory apparatus to simulate the reactions taking place in the blast furnace The *Scice* apparatus (stationary charge in controlled environment) metaphorically turns the blast furnace 'inside-out' In the blast furnace the charge moves down the stack, encountering changing conditions and undergoing various reactions, in *Scice* the charge is held stationary while gas of varying compositions and temperatures corresponding to these changing conditions is passed through it and reacts with it By controlling the conditions continuously, the ironmaking process can be reproduced and its reactions studied with relative ease

The practicability of this approach was originally proved in the laboratory by experiments using a charge container of three inches diameter A much larger and more elaborate version has now been installed at the Battersea Laboratories It incorporates a gas producer, gas absorbers, gas booster, electric heater for the gas, a reaction chamber 20 in in diameter by 24 in high, dust cyclone, and a gas cooler Instrumentation has been provided for flow-rates, temperatures, pressures and gas compositions, with provision for easy control of the variables This scaled-up version of the original bench conception provides a unique tool with which to solve some of the remaining unknowns about blast furnace operation

Also housed at Battersea is the Association's Operational Research Department, which now consists of three Sections Computer Applications, Operational Investigations and Human Factors

The first of these is primarily concerned with helping the steel industry to make use of the electronic computer This involves the use of the computer not only as a research tool but also as an administrative and/or production aid Using the Ferranti *Pegasus* computer installed at Battersea in 1958, the Section has carried out extensive studies of the feasibility and economics of using computers for such familiar problems as production scheduling, stock control, wage calculation, plant and process control, and allocation of materials, and already much valuable data have been collected

The Operational Investigations Section is operating a service—at present confined to the Association's member firms—whereby the Department's experience and facilities can be used to supplement managerial experience with forecasts of the effects of alternative policies A typical problem, involving a decision on stock control methods, was illustrated by displays The example taken was a company keeping large stocks of billets to ensure against production hold-ups This involved problems of locked-up capital and periodic rises in storage and transport costs

The first step was to analyse existing order and stock control methods From this, and from quantitative records, the main characteristics of production and raw material delivery over a long period were mapped out, and the effects of different control methods simulated on paper and carefully studied

Eventually, a set of 'ordering rules' was drawn up which in practice proved so successful as to release £100,000 of working capital by reducing the average stock-level, and a further saving of some £6,000 annually by reduced labour and transport costs

The Human Factors Section of the Department is concerned with such things as accident prevention, protection against heat and injury, and the broad subject of ergonomics, or 'fitting the machine to the man' In this latter field, displays showed many advances in control equipment design, aimed at reducing operator fatigue, eliminating strain and increasing efficiency An experimental control point was on display incorporating variable hand (and foot) controls, which has proved the genesis of a series of improvements already being adopted in production practice

It is, of course, impossible to give other than an arbitrary selection of the features of the display which, in any event, was representative of a part only (about one-third) of the whole programme of the British Iron and Steel Research Association This account, however, provides an indication of some types of problem being tackled and of the methods of approach

D U Hunt

COMPUTER LABORATORY AT THE UNIVERSITY OF LIVERPOOL

THE University of Liverpool has had a Mathematical Laboratory for more than twenty-five years—it was established by Prof L Rosenhead in 1934 shortly after he became head of the Department of Applied Mathematics The primary object of the Laboratory was always to train students in the honours school of mathematics and research students in other schools in the basic methods of numerical analysis applied to all branches of science

The Laboratory has always been well equipped with accounting machines as well as desk calculating machines An important feature of the teaching in the Laboratory has been the insistence on the fullest possible exploitation of all types of calculating aids, and much effort has been spent on not only investigating the possible uses of machines but also on developing methods suitable for them

The spectacular post-war growth in the demands for numerical analysis has led to very greatly increased demands being made on the Laboratory, the problems received for solution have been growing more numerous, more complex and greater in scope At first, the need was met in part by making use of punched card accounting machinery, and later by using the facilities of electronic computing establishments elsewhere—particularly at the University of Manchester, the generosity of which in this respect has been greatly appreciated by several other northern universities as well as Liverpool More than four years ago, however, it was already clear that the University of Liverpool should be equipped with its own computer, and detailed plans were made for the expansion of the Laboratory It was therefore with very keen disappointment that the University learned two years ago that money could not be provided at that time by the University Grants Committee for the provision of a computer

A survey made in the University had established the fact that the lack of an adequate computing service was causing research in some departments to be retarded seriously—particularly in the fields of nuclear physics and oceanography In view of this situation, the University Council decided that a computer must somehow be provided and an appeal was launched among local business concerns and friends of the University for donations towards the cost of purchasing a machine The response was generous—particularly as the appeal was made within a year of the major appeal to finance the general building development of the University—and as a result the University was able to place an order with the English Electric Co , Ltd , for a *Deuce*, the remaining balance of the cost being advanced by the University itself At the same time the staff of the Laboratory was increased and its name changed to the Computer Laboratory, Mr Andrew Young being appointed as its first director

The machine was installed and came into operation last July It is a 64-column *Deuce*, which is at present equipped with punched card input and output mechanisms A comprehensive range of punched card ancillary equipment—card punches, sorter, reproducer and tabulator—has also been installed, a card-operated typewriter is due for early delivery In addition, paper tape input and output devices and the necessary tape editing ancillary equipment have been ordered, but have not yet been delivered

The Computer Laboratory was officially inaugurated at an open day held on October 28, when the University entertained donors to the appeal fund and members of Council and Senate The guests were welcomed by the Vice-Chancellor, Sir James Mountford, and were shown over the Laboratory by the staff, the Director gave an account of the work being done in the Laboratory

It is already clear that the computer is meeting a very real need Extensive use of the machine is being made, as expected, by the Departments of Applied Mathematics, Physics—mainly analysing results of experiments made on the University's large synchrocyclotron—and Oceanography as well as several departments in the Faculty of Engineering, including the new Department of Building Science

What has surprised—and gratified—the University, however, is the unexpectedly large use of the machine by departments which had not hitherto been expected to use it extensively, if at all Some of the most frequent users are members of a group of physiologists working on a problem of liver function Members of the Department of Psychology and of the Medical Research Council are now analysing the results of gerontological studies with the computer, which, because of its ability to cope with the heavy arithmetic involved in factor analysis, has enabled them to extend their work In addition, educational, economic and social scientific surveys have been helped by the new computing facilities available

Training in programming and using the computer and its ancillary equipment is given regularly to members of the staff of the University, research students, and to outside users, a number of whom are making use of the machine on a basis of time-hire

It is now a commonplace occurrence that the installation of a computer leads to an expansion in the scope of the work undertaken in an institution, and it is already abundantly clear that in this respect the installation in Liverpool will prove to be no exception The University is proud of its new project, and is confident that the decision to embark on it will be fully justified

BRITISH ELECTRICAL AND ALLIED INDUSTRIES RESEARCH ASSOCIATION

A NEW format has been adopted for the 1958 annual report of the Electrical Research Association (Thirty-eighth Annual Report for the year ended 31st December 1958 Pp 103 Leatherhead Electrical Research Association, 1959) The report, which is attractively reproduced, departs from previous practice in having some fifteen illustrations, mostly photographs relating to research projects One diagrammatic illustration of special interest shows the proportions of the income of the Association coming from various sources and the distribution of expenditure among the main fields of research, in administration and in services to members

The total income of the Association for the year was just over £458,000, subscriptions from members totalling some £213,000, income from directly sponsored researches earning nearly £113,000, and the grant from the Department of Scientific and Industrial Research contributing £100,000 From the chart showing the distribution of expenditure it appears that some 9 per cent is used in administration A slightly greater amount represents services to members which, in addition to general technical liaison, cover the answering of requests for advice and information and the provision of abstracts Research expenditure appears under seven headings, divided as percentages of the total expenditure, roughly, as follows

Properties of materials	19	Applications of electricity	12
System problems	14	Transmission	6
Control and transformation	10	Specialized plant	10
		Miscellaneous researches	9

On the basis of expenditure, properties of materials thus represents, by a substantial margin, the biggest research effort of the Association, and it is evident from the report that this effort, which is devoted largely to insulation, has contributed both to fundamental knowledge and to technological progress. Much of the Association's technological work in this field has contributed to the drafting of British Standard specifications and similarly, at the international level, to the recommendations of such bodies as the International Electrotechnical Commission. During the past year the Electrical Research Association's recommendations relating to electrode systems for electric strength tests and for methods of measurement of permittivity and loss angle have been so adopted.

Work conducted at the National Physical Laboratory on the effects of electron and neutron irradiation of polythene is reported. It has been shown that the loss tangent of the material is little affected by irradiation dosages up to 10 Mrads, but thereafter increases due to oxidation.

Among the investigations of a fundamental character concerning the phenomena of instability in dielectrics, one may be mentioned dealing with the formation of gas in impregnated insulation. This has established the relation between moisture content and the stress required to initiate gas production. It has been possible to observe the slow growth of breakdown channels in a very viscous liquid and this forms the subject of one of the illustrations in the report.

A reliable technique has been developed for measuring the electric strength of liquefied gases, it having been established that the state of the electrode surfaces and particularly the degree of oxidation have a marked influence on the result. The parts played by anode and cathode have been separated by using electrodes in which the cathode and anode surface were different.

The influence of impurities on the magnetic properties of silicon–iron transformer sheet has been under investigation at the laboratories of the British Iron and Steel Research Association. It has been shown that, with respect to hysteresis loss, nitrogen is much more harmful than carbon, and two methods of minimizing the ill-effects of nitrogen are being examined. One method involves applying a thin coating of aluminium to laminations before annealing while the other utilizes a small admixture of titanium.

Theoretical work on deviations from Ohm's law in semiconductors has predicted that in sufficiently strong fields mobility should decrease with the 0·8th power of the field strength. This prediction has been confirmed by measurements made at Purdue University.

Circuit breaking and associated fundamental studies in arc physics continue to constitute an important part of the research programme. The temperature within the conducting core of the arc and, in particular, the formation of successive discrete cores as the current increases, have been studied in terms of dissociation and ionization, and it has been shown that the pinch pressures occurring at the electrodes outweigh the effects of natural convection and may provide an explanation of the phenomena of metal transfer in welding arcs.

Work on the creep properties of steel continues and is being extended. The first test-results have been obtained on the bursting of thick-walled pipes under creep conditions. A new laboratory to meet the needs of the augmented programme of work on creep testing is to be built at Leatherhead.

A result of considerable industrial significance has been obtained in the course of the programme of work on flame proofness and intrinsic safety. A re-evaluation of the maximum safe-gap for hydrogen made with improved research technique has shown the safe gap to be appreciably greater than was previously accepted. The value has been established as 11 mils. This opens up the possibility of designing flame-proof apparatus for use in hydrogen and some of the other most explosive gases.

The rural electrification work of the Association, which is concerned very largely with the application of electricity to agriculture and to horticulture, has, in the past, embodied a considerable programme of research on plant environment. This continues but it is now supplemented by a parallel programme on animal environment.

In a foreword to the report the president, Sir Josiah Eccles, points out that we are entering an era in which the scale and complexity of equipment and of automatic control systems will be such as to render capital charges a dominant factor in industrial costs. There will thus be an increasing premium on ingenuity and skill in producing more effective and cheaper equipment which, in effect, means an increasing emphasis on research. Bearing in mind that the vast majority of manufacturing firms in Great Britain employ less than 500 people and that many problems can be better tackled co-operatively than in specialized laboratories, it is evident that research associations have an important part to play in the effort to develop to the full the nation's scientific potential. In furthering this development the greatest responsibility falls, almost certainly, to the electrical industry. J. Greig

FLOW PROPERTIES OF BIOLOGICAL SYSTEMS

A MEETING, under the joint auspices of the Faraday Society (Colloid and Biophysics Committee) and the British Society of Rheology, was held during September 23 and 24 in the School of Physiology of the University of Oxford. On the first day, the flow properties of various biological systems were discussed, while the second day was devoted entirely to blood and blood vessels. The attendance of more than seventy included a number of overseas guests.

The Conference was opened by Prof. P. R. Allison, Nuffield professor of surgery, who welcomed the meeting to Oxford and spoke of the increasing importance of rheology in medicine and surgery. A general introductory lecture, under the chairmanship of Prof. M. Reiner (Haifa, Israel), was given by Dr. A. S. Lodge. Many of his audience were not rheologists and, for their benefit, Dr. Lodge outlined the scope and methodology of this branch of physics.

Several papers were read which concerned uterine cervical mucus and the connective tissue of the cervix. Dr. F. K. Beller (Tübingen, W. Germany) described the rheological changes which take place in human mucus during the menstrual cycle and following certain hormone treatments, and Dr R A Gibbons and Mr F A Glover (National Institute for Research in Dairying, Shinfield) discussed measurements of flow birefringence and the information which these might give concerning the size and shape of mucoid molecules Drs M L R and D R Harkness (University College, London) were concerned with the very marked changes which must take place in the lower end of the uterus and in the cervix to allow of the passage of the fœtus at parturition The concentration of collagen drops from 10 per cent (wet basis) in the non-pregnant animal to about a third of this amount during pregnancy

Drs J C White and P Elmes (London Postgraduate Medical School) described viscosity, intrinsic viscosity and thixotropy measurements on dilute bronchial mucoid sputum A special apparatus was designed to measure the yield-values of undiluted samples, which may be related to the force required to initiate movement of the mucus in the smaller respiratory passages Dr H J Rogers discussed hyaluronidase and hyaluronic acid

Living skeletal muscle has remarkable rheological properties, contracting rapidly and completely from extensions of up to 130 per cent, but this extreme elasticity is quickly lost *post mortem* J R Bendall (Low Temperature Research Station, Cambridge) spoke of the form of the deformation-time curves and the biochemical processes underlying the changes which take place in them Also concerned with muscle, Dr J J Connell (Torry Research Station, Aberdeen) described measurements of toughness and firmness of fish and of fish pastes and jellies as related to subjective assessments

Prof L V Heilbrunn (Philadelphia) discussed methods for measuring the rheological properties of protoplasm, and stressed the differences between these and the behaviour of purified proteins Prof J A V Butler and Dr A B Robins (Chester Beatty Research Institute, London) described simple viscometric measurements (using concentric cylinders) for the study of nucleic acid solutions , and the significance of intrinsic viscosities and of viscous anomalies such as dependence of viscosity on shear rate

Dr G W Scott Blair (National Institute for Research in Dairying, Shinfield) read two papers, the first of which dealt with the rather complex properties of milk coagulated by rennet which, at best, requires four parameters for its specification ('Burgers body') On the second day, he described similar experiments on coagulated blood, which, surprisingly enough, except in the earliest stages, requires only two parameters ('Maxwell body')

The symposium on blood was introduced by Dr L W Bayliss (University College, London) under the chairmanship of Prof I de Burgh Daly Dr Bayliss outlined studies which have been made on viscous anomalies in blood flowing through artificial capillaries, emphasizing the importance of the relatively easier flow which is found in the narrower tubes and which reflects axial movement of corpuscles Dr R L Whitmore (Nottingham) gave a theoretical treatment of these differential flow velocities of plasma and corpuscles in the living body By means of radioactive tracers, changes in concentration due to radial movements can be followed He discussed turbulent conditions, which also formed the theme of a paper by Dr W E Stehbens (Sydney, Australia and Oxford), who pointed out that, especially in the neighbourhood of bifurcations, turbulence takes place at quite low Reynolds' numbers Nor must the pulsatile nature of the flow be forgotten Streamline conditions are not as general in the body as used to be supposed Dr D A McDonald also discussed the hydrodynamics of pulsatile flow, basing his treatment on the theoretical work of the late Dr J R Womersley and of Dr M G Taylor

Prof A L Copley (New York and London) discussed the nature of the flow-curve of blood in glass capillaries which has recently been shown to follow Casson's equation (see G W Scott Blair, Nature, 183, 613 , 1959) When the surface of the capillary is coated with fibrin, the apparent viscosity falls and the differential flow velocities appear to be accentuated Moving 'indexes' of blood in sloping capillaries also adhere less to fibrin than to glass surfaces In the living blood vessel, an endo-endothelial fibrin film may constitute a major factor in helping circulation He also presented work on native blood and plasma and the effects of anticoagulants

Prof S Baez (New York) described pressure effects in living microscopic vessels and pointed out the important part which the tone of the vasculature plays, not only in hæmodynamics but also in those studies now often referred to as 'hæmorheology' Dr H Hartert (Heidelberg, Western Germany) discussed the rheology of his well-known technique for following the process of blood coagulation by measuring the progressive increase in shear modulus ('thrombo-elastography') and also described his more recent invention, the 'retractograph', which follows the process of retraction, claimed to start immediately at the clotting point and to increase in parallel with increase in the shear modulus Dr H H Pfeiffer (Bremen, Western Germany) described his measurements of rheodichroism, a phenomenon which throws much light on the molecular nature and characteristics of the so-called 'leptones' which are responsible for differential light absorption in flow Prof A Katchalsky (Rehovoth, Israel) and his colleagues discussed recent experiments on osmotic effects in individual erythrocytes These behave rather like football bladders, in that they are very readily deformed up to a certain degree of swelling, after which they offer enough resistance for the pressure quickly to exceed their apparent strength, a fact which may help to account for the comparative ease with which red cells appear to pass along very narrow vessels

In the afternoon of the second day of the meeting, there was an exhibition of apparatus Many of the instruments associated with the papers which had been read were on view The demonstrations were introduced by a lecture by Prof K Weissenberg in which he showed many strange rheological phenomena which, in less dramatic form, are likely to make their appearance in biological systems His own 'rheogoniometer' was among the exhibits

In the evening, films were shown which developed further the themes already described by Dr D L McDonald and his colleagues, by Prof S Baez and by Prof A L Copley, Dr G W Scott Blair and their colleagues Finally, Prof M H Knisely (Charleston) showed a film to illustrate his work on 'sludged blood'

Much of the success of the meeting was due to the excellent local organization, in the hands of Dr R G Macfarlane, who also acted as honorary treasurer The proceedings of the Conference will be published in book form early in the New Year under the joint editorship of Prof A L Copley and Dr G Stainsby

G W SCOTT BLAIR

BRITISH COLONIAL TERRITORIES

"THE Colonial Territories, 1958–59"* provides the usual convenient compendium of information to such further publications as "Colonial Research" dealing with the British Commonwealth and itself includes a 24-page chapter dealing with "Research and Surveys", to which grants totalling £800,824 were made from Colonial Development and Welfare Funds for a further 134 research schemes The recommendations of the meeting at Lagos in January 1958 for the future organization of research in West Africa have now been accepted by the Governments of Ghana, Gambia, Nigeria and Sierra Leone, and the West African Research Office came formally into being on April 1, 1959 The Government of Ghana has now abandoned its intention of taking over the West African Cocoa Research Institute, which will accordingly continue as a fully inter-territorial research body The Commission for Technical Co-operation in Africa South of the Sahara has decided to transfer the headquarters of the joint secretariat from London to Lagos

Approved technical assistance projects in the British-dependent territories in 1959 under the United Nations Expanded Programme of Technical Assistance (to which the United Kingdom Government at present contributes the sterling equivalent of 2,240,000 dollars a year) amounted to 1,062,750 dollars Expenditure from Colonial Development and Welfare Funds was £17 8 million and the Vote for Colonial Services included £24,223,000 as financial aid to Colonial Governments Exports (excluding Northern Rhodesia and Nyasaland) fell by £46 million and imports by nearly £80 million, including about £35 million in Hong Kong and Singapore and nearly £20 million in East Africa Capital formation in 1958 remained at about the same value as in 1957

Among some other points which may be mentioned are the rapid expansion of educational facilities, although the provision of new school places and additional teachers remains the over-riding problem in most territories In October 1958, the two universities and three university colleges in Central Africa had 3,783 students, compared with 3,400 the previous year, and there were 1,615 students at the University of Malaya, which serves Singapore as well as the independent Federation of Malaya Capital sums provided under the Colonial Development and Welfare Act for university institutions are now almost completely committed, and a main financial problem is now to provide the required increase in accommodation for residence and teaching The Singapore Polytechnic opened in November 1958 with 385 full-time, 506 day-release and 2,005 evening students, and a second new technical college in Jamaica opened in March 1958 with 60 students In Jamaica, 11,000 extra primary places were provided out of the 16,000 required, and in Uganda the number of African pupils in aided secondary schools has risen from 5,517 in 1951 to 17,306 in 1958

Attachments of American teachers to institutions in British Colonial territories continued under the Fulbright Agreement, and the Overseas Visual Aids Centre was officially opened in London in February Departments of health generally were able to meet increasing demands on all services while maintaining a fair balance between curative and preventive work Mass campaigns and surveys or pilot projects preceding them have been used extensively to combat endemic diseases, but although the incidence of malaria and yaws has been dramatically reduced in this way, tuberculosis remains a serious problem Progressive improvement in water supplies in rural and urban areas has considerably assisted the control of water-borne diseases The Institute of Health in Singapore was completed in 1958 with assistance of a grant of 1,500,000 dollars from Colonial Development and Welfare Funds, and during 1958, 144 medical students and 5 dental students from the Colonial territories were placed by the Colonial Office in teaching schools in the United Kingdom and the Irish Republic Several overseas governments are now contributing to the Applied Nutrition Unit at the London School of Hygiene and Tropical Medicine

GERM-FREE VERTEBRATES: PRESENT STATUS

IN a recent publication by the New York Academy of Sciences résumés are given of a series of papers delivered at a conference held by the Academy during May 1958* It is divided into five parts the first and second are concerned with instrumentation and with rearing of germ-free vertebrates, the third is concerned with the biological characteristics of germ-free animals, the fourth and fifth describe ways in which germ-free animals have been successfully used as a tool to solve otherwise intractable problems and discusses future possibilities in this direction

It has taken thirty years of technical development to produce germ-free animals of most laboratory species and thereby refute the opinion of Pasteur that germ-free animals would not survive Although the methods adopted are subject to continuous improvement, simplification and standardization, they remain expensive and complex Nevertheless, the time has come when germ-free animals are produced on a limited scale for practical research projects and, since the maintenance of the germ-free state over a limited time is much simpler than the production of germ-free animals, a plea is made for wider support for centres to produce and distribute them Study of the physiology and nutritional requirements of germ-free animals is a necessary preliminary to their use in research In this connexion, it is noted that their lymphoid tissue is immature compared with that of conventional animals Plasma cells are present in small numbers and the amount of serum γ-globulin is much reduced.
